I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Ginny Masullo

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 2:33:08 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Heather Beck

Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

J Morgan Chism-Diebold

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

Dear Arkansas Department of Environmental Quality,

I really don't think Arkansas can truthfully call itself The Natural State while outgassing coal burning pollution. I grew up in Arkansas and I don't want pollution to harm me and my family, the wilderness areas nor citizens of our neighboring state Missouri. Let's focus on clean alternative energy!

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Jane House

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Sunday, January 07, 2018 8:50:54 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Jo Johnson

Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

John Moszyk

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Julia Ranft

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 4:24:00 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Katherine Alexander

Dear Arkansas Department of Environmental Quality,

I live in the other direction from St. Louis. I live in South Arkansas. I moved here 4 years ago from Central Mississippi. I use a CPAP machine nightly. One filter in my CPAP machine would begin to look dirty in Mississippi after 6 months use. Another after a year. Here in South Arkansas, they look dirtier after one weeks use than what I just wrote about my Mississippi experience. Also, I am a gardener. The soil here is different and for awhile I couldn't remember what it reminded me of. It finally dawned on that the soil in South Arkansas reminds me of the ash heaps in Saltville, Virginia, that are now an EPA Superfund Site.

And, I am 60 years old and used to teach. When I visit my granddaughter's schools, I am always astounded at what to me seems like a very high number of special needs children. I am worked in schools in towns and counties with a similar number of people, but which did not have this many special needs students. Also, I see larger numbers of special needs adults that I am used to from living in cities outside of Arkansas. There seems to be something very very wrong here and I suspect it is in the environment. This is a terrible strain on individuals, their families and government programs like Social Security Disability. Taking care of our environment is the most important issue to me. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Kenneth Koniczny

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 2:47:12 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Laura Allers-Lowry

This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Linda Wigger Kraft

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

We need to protect the health and lives of Americans. We cannot do that and simultaneously support coal fired plants in Arkansas. Please, please end coal pollution being generated by Arkansas plants. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Margaret Lincourt

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 5:03:47 PM

Dear Arkansas Department of Environmental Quality,

Stop coal pollution now! All living things deserve to breathe clean air.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Mary Cornell

The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Michael Garner

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Dear Arkansas Department of Environmental Quality,

Coal is dead - these companies just don't know it. Get with the future; clean up your mess.
In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Nancy Schick

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 6:02:58 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Patrick Keough

The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Philip Fredericks

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. Dear Arkansas Department of Environmental Quality,

Unbelievable that this technology has not been already required. Renewable energy and end-user conservation alternatives should be pursued as well.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Richard Dietzen

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Thursday, January 18, 2018 7:31:48 AM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Roy and Jill Moed

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Shari Farrar

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

You must know about the technology that prevents this pollution. Such pollution is going to make life increasingly difficult for generations to come. It is not going to go away.

There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Stephanie Holbert

Dear Arkansas Department of Environmental Quality,

Sop working against the health of the people of the United States!

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Susie Getzschman

Dear Arkansas Department of Environmental Quality,

Xcel Energy in Colorado got 96 bids at a median price of \$18.10 per MWH for over 42 GW of wind alone and 11 bids on wind plus battery storage at a median price of \$21 per MWH for a total of 5.7 GW. The incremental increase from the storage is less than the cost of a gas turbine peaker plant. This is presumably due to the extremely low cost of electricity from wind in Colorado, while natural gas peakers are the source of the most expensive marginal electricity prices because of the inefficiency of peakers in burning NG. For solar PV, Xcel got 152 bids at a median price of \$29.50 per MWH for a total of almost 30 GW of total bids, and 87 bids on solar PV and battery storage at a median price of \$36 per MWH for almost 17 GW of total bids. The last are similar to merely operating the dirty coal plants at White Bluff and Independence. Arkansas has better solar resources than Colorado. The wind plus storage bids are cheaper than the operating cost of the White Bluff coal plant. SW EPCO shows that Arkansas utilities can access some of the cheapest wind electricity in the world with Capacity Factors above 50%.

SWEPCO to save customers over \$5 billion by buying 1.4 GW of 50% CF wind power from Oklahoma. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Thomas Franck

Dear Arkansas Department of Environmental Quality,

We as human beings are now at a particular time in our history to make decisions that will guarantee whether or not we will have a future at all. Those of us with the power to make changes that will save lives still seem more preoccupied with the kind of profiteering off of toxic energy sources that will ultimately poison our planet while simultaneously destroying the resources (air/food/water) that no living being can survive without. When smoke and toxic fumes dissipate into our air...It is still there. When oil, coal ash, fracking chemicals, and nuclear waste leaks into our oceans, lakes, rivers, and groundwater...It is still there. When any of these toxins seep into our earth...It is still there.

"Out of sight" may mean "out of mind" to those lacking common sense, but the more we pour poisons into our environment, the more we will feel and see the effects...and ultimately all life will end without a sustainability agenda that all humans must honor. The path we are already on leads only towards a slow suicide on a planetary scale...and it picks up speed every day we ignore the truth.

North Little Rock, AR 72118

RE: Comments on Proposed Revisions to the 2008 Regional Haze State Implementation Plan

Dear Ms. Treece:

Arkansas Electric Cooperative Corporation (AECC) respectfully submits these comments on the Proposed Revisions to the 2008 Regional Haze State Implementation Plan (SIP). As the owner or co-owner of seven electricity generating units discussed in the proposal, AECC has much interest in the outcome of this plan.

AECC's ownership of these units is described below.

- 100% of Carl E. Bailey Generating Station Unit 1;
- 100% of John L. McClellan Generating Station Unit 1;
- 50% of Flint Creek Power Plant Unit 1;
- 35% of White Bluff Steam Electric Station Units 1 and 2; and
- 35% of Independence Steam Electric Station Units 1 and 2.

AECC supports ADEQ in its decision to replace the federal implementation plan (FIP)¹ with a SIP. AECC believes that, as proposed, the SIP is a very beneficial improvement over the FIP – not only for AECC and its members but also the state as a whole.

AECC agrees with ADEQ that no add-on controls beyond best available retrofit technology (BART) controls are necessary for reasonable progress during the 2008-2018 planning period.² AECC agrees that installation of add-on controls is neither reasonable nor necessary to achieve reasonable progress for the 1st planning period. This is especially true since monitoring data

¹ Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule (81 FR 66332, September 27, 2016)

² Proposed Revisions to the 2008 Regional Haze State Implementation Plan at 46 (Issued by ADEQ on October 31, 2017)

demonstrates that Arkansas' two Class I areas are currently meeting their Reasonable Progress Goals and are expected to continue to meet those goals through the second planning period.³

AECC requests that ADEQ edit the language describing the White Bluff plant as "installed in 1974." The two units at the White Bluff plant meet EPA's definition of "in existence" in 1974 which makes them BART-eligible; however, the two units were not commissioned until 1980 (Unit 1) and 1981 (Unit 2).

Specifically, in the second paragraph in Section D on page 21 of the proposed SIP, AECC requests that "installed in 1974" be changed to "in existence in 1974".

AECC requests that ADEQ remove any language that may indicate that the two Independence units are nearing the end of their useful lives. The term "aging" is used to describe the Independence plant on page 47 of the proposed SIP. AECC believes that these units are designed to operate for 60 or more years if maintained properly; therefore, given the commissioning dates of these units, they have several decades of useful life remaining.

AECC requests that the word "aging" be eliminated from the description of the Independence plant on page 47 of the proposed SIP.

This concludes AECC's comments.

Sincerely,

Stephen Cain
Manager – Environmental Compliance

Re: Revisions to Arkansas Regional Haze State Implementation Plan (AR RH SIP)

Dear Ms. Treece:

The Arkansas Environmental Federation (AEF) is a non-profit association with over 200 members, primarily Arkansas businesses and industries that manufacture products, provide services, and employ skilled workers in Arkansas while also insuring that their operations comply with all federal and state environmental, safety and health regulations. As such, the AEF and its members have an ongoing interest in the State's Regional Haze SIP. We respectfully submit the following analyses:

The U.S. Environmental Protection Agency (EPA) has recently granted reconsideration to certain aspects of the 2017 Regional Haze Rule Revisions¹. In light of this reconsideration, as well as the ongoing legal challenges to these 2017 revisions, ADEQ should avoid reliance on the 2017 revisions and associated draft guidance in the development of this Regional Haze SIP.

ADEQ takes inconsistent positions in its Petition for Reconsideration of the FIP and the proposed replacement SIP regarding the need for a reasonable progress analysis. Arkansas is already below the glidepath for the first planning period, so no reasonable progress analysis is necessary. Arkansas appealed the FIP based on the imposition of controls even though the State was already meeting the reasonable progress goals EPA established in the FIP, but the State is now relying upon the same assessment that it appealed in crafting the replacement SIP. The State should continue to find that a reasonable progress analysis is not necessary to evaluate controls where evidence indicates that Arkansas will achieve reasonable progress without any controls.

The threshold issue when addressing reasonable progress is whether further actions are *necessary* to ensure that visibility improvement is continuing on or below the glidepath. The CAA requires implementation plans to “contain such emission limits, schedules of compliance and other measures as

¹ <https://www.epa.gov/visibility/epas-decision-revisit-aspects-2017-regional-haze-rule-revisions> (Jan. 18, 2018)

may be necessary to make reasonable progress.” See 42 U.S.C. § 7491(b)(2) (emphasis added). Consistent with this, EPA’s Reasonable Progress Guidance² makes clear that reasonable progress controls may not be necessary in the first planning period, noting that, “[g]iven the significant emissions reductions that we anticipate to result from BART” and other Clean Air Act programs “it may be all that is necessary to achieve reasonable progress in the first planning period.”). Reasonable Progress Guidance at 4-1. See also, *id.* at 1-4 (“[Y]ou should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for you to defer reductions to later planning periods in order to maintain a consistent glidepath toward the long term goal.”). ADEQ may require additional controls only if further action beyond BART and other CAA programs is *necessary* for reasonable progress in this planning period.

ADEQ’s current approach also may limit its ability to change course in the second and subsequent planning periods. An EPA approval of ADEQ’s decision to perform an unnecessary reasonable progress analysis may limit ADEQ’s discretion if it were to determine in a future planning period that a reasonable progress analysis is unnecessary under similar conditions (i.e., visibility improvement is on or below the glide path based on emissions reductions already occurring so that further controls are not needed). ADEQ might be forced to assess reasonable progress controls even if visibility improvement exceeds the goals, increasing the likelihood that future unnecessary controls would be imposed upon Arkansas point sources.

ADEQ’s focus on a source-specific reasonable progress analysis sets a precedent that could force more sources to install controls in the second planning period. EPA’s guidance makes it clear that states have flexibility in evaluating the statutory factors and including other factors determined to be relevant but ADEQ has focused its analysis narrowly and failed to consider other important factors. More troubling, ADEQ’s approach endorses the very Regional Haze Rule revisions that EPA has adopted which limits state discretion in conducting reasonable progress analyses. This is particularly troubling for Arkansas given that it is already below the glidepath for the first planning period. ADEQ is unnecessarily setting a precedent that may be difficult to avoid for future planning periods.

If ADEQ determines a reasonable progress analysis nonetheless is required, then it should be a broader analysis than the one ADEQ conducted, looking at more sources and at all relevant factors rather than a source-specific analysis. Specifically, such an analysis should look at all relevant sources as well as beyond the four statutory reasonable progress factors: (1) non-air quality environmental impacts, (2) cost of compliance, (3) time necessary for compliance, and (4) RUL. See 42 U.S.C. § 7491(g)(1).

ADEQ is not limited to consideration of the four factors mandated by the CAA. Instead, ADEQ has authority to consider other relevant factors, and it should do so here. EPA’s Reasonable Progress Guidance, which applies to the first planning period, is clear that the four statutory factors are the *minimum* that ADEQ must consider. In other words, when determining reasonable progress, states can consider other factors that it has found to be relevant. See Reasonable Progress Guidance at 5-1 (“In determining reasonable progress, CAA § 169A(g)(1) requires States to take into consideration a number of factors. However, you have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant.”). ADEQ also is not limited to an analysis that mirrors a BART analysis in analyzing reasonable progress controls. For example, EPA has explained

² U.S. EPA, *Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program* (June 1, 2007) (hereinafter Reasonable Progress Guidance”). Available at: https://www3.epa.gov/ttn/naaqs/aqmguide/collection/cp2/20070601_wehrum_reasonable_progress_goals_reghaze.pdf.

that the cost of compliance factor for reasonable progress purposes – one of the factors that overlaps with a BART analysis – “can be interpreted to encompass the cost of compliance for individual sources or source categories, and more broadly the implication of compliance costs to the health and vitality of industries within a state.” Reasonable Progress Guidance, at 5-1.

In summary, ADEQ should:

- Continue to find that a reasonable progress analysis is not necessary to evaluate controls where evidence indicates that Arkansas will achieve reasonable progress without any controls; and
- Resist the application of source-specific reasonable progress analysis under the circumstances, i.e. visibility improvement is on or below the glide path based on emissions reductions already occurring so that further controls are not needed.

Thank you for your attention to this matter and the opportunity to comment on the pending revisions to the Arkansas Regional Haze State Implementation Plan.

Sincerely,

Charles M. Miller

Subject: Regional Haze: SIP Revision

I am writing in to express my outrage that the Arkansas Department of Environmental Quality (ADEQ) is proposing to weaken the plan that the EPA created for our state. Clean air is essential to the health of the people of Arkansas and also to the health of the animals and plants of our state. ADEQ should be holding the power companies that are polluting our air to higher standards not trying to allow them to continue with pollution business as usual. Please scrap this weak plan and adopt the stronger plan that the EPA wrote for us. I understand that ADEQ failed to come up with our own plan earlier which necessitated that the EPA write a plan for us. ADEQ is not living up to its name, that's for sure. Please put in place changes that will improve the air quality in our wild areas as well in the whole state.

Subject: Arkansas State Implementation Plan for Regional Haze
Date: Monday, January 22, 2018 8:54:06 PM

Ms. Treece,

I am writing to express my concern regarding revisions to Arkansas's Regional Haze SIP.

Haze reduction is more than a decade overdue in Arkansas, yet ADEQ's proposed plan will delay haze reduction even further. ADEQ should not reject the robust EPA plan in favor a plan that will result in dirtier air and less haze reduction in our parks. If not for ADEQ's decade of delay and obstruction, we would be well into implementing the EPA's haze reduction plan and improving visibility in our Arkansas parks and wilderness areas that I cherish.

I ask that ADEQ revise its proposed plan to include scrubbers on the massive White Bluff and Independence coal-burning power plants. SWEPCO's Flint Creek coal-burning power plant installed a scrubber last summer, and now it is time for White Bluff and Independence to have scrubbers. I also ask that ADEQ's plan retain source-specific NOx limits instead of the trading program.

ADEQ should stop delaying haze reduction and do its job! Be a proponent for high air quality.

Sincerely,

Daniel Scheiman

Subject: Clean Air Act Hearing
Date: Friday, January 19, 2018 7:38:37 AM

Ms. Treece,

My name is Mason Jewell and I am a junior at the University of Arkansas. It has come to my attention that the ADEQ's Haze Reduction plan required by the Clean Air Act has some major issues. By not requiring scrubbers at coal-burning power plants we are ensuring that haze, and the harmful particles that make it up, continue to damage both the aesthetic beauty of our Natural State, and the health of the people, plants, and animals that call it home.

An emissions trading program in lieu of point-source limits defeats the purpose of the initiative. Power plants will continue to release harmful emissions into the air, and while the statewide average may be reduced, those areas surrounding each plant will get the same amount of, if not more, pollution.

As a college student and now majority age citizen, actions like these from an institution that is supposed to protect my environment, *my home*, are worrisome. I hope that your organization will make the decision that is in the best interest of the state and its people, not the power companies. My generation is watching and planning for the inevitable repairs that will have to be made to existing societal systems. Don't add this issue to a growing legacy of environmental blunders. It's not too late.

Sincerely,
Mason Jewell

Guys,

We need cleaner air and water, not less so. I want to climb Pinnacle and not see haze in every direction. I want to save more elderly and children from premature deaths due to exposure to particulate matter. I'd like to eat the fish I catch without fear of exposure to too much mercury. Please do your jobs and put the needs of the majority of Arkansans over the greed of the few that profit from polluting. We can grow our economy and invest in clean energy jobs and have cleaner air and water. It's not either/or.

sincerely,

Matthew Bintliff

Re: Proposed Revisions to the Arkansas State Implementation Plan – Regional Haze SIP
Revisions for 2008-2018 Planning Period, October 2017

Dear Ms. Treece:

Domtar appreciates the opportunity to provide comment on the Arkansas Department of Environmental Quality (ADEQ) proposed revisions to the Arkansas State Implementation Plan (SIP) addressing Regional Haze SIP revisions for the 2008 to 2018 planning period (the 1st planning period). As noted in these comments, we are respectfully asking ADEQ to revise portions of the proposed SIP to ensure consistency with positions previously taken by the State in challenging the EPA's Arkansas regional Haze Federal Implementation Plan.

Domtar is a leading provider of a wide variety of wood fiber-based products, including communication, specialty and packaging papers, market pulp and absorbent hygiene products. The foundation of our business is a network of fiber converting assets that produce papergrade, fluff and specialty pulps. While most of our pulp production is consumed internally to manufacture paper and consumer products, we are also a large volume pulp vendor, with significant amounts of both market pulp and fluff pulp sold to customers around the globe. Domtar is the largest integrated marketer of uncoated freesheet paper in North America. With approximately 9,700 employees serving more than 50 countries around the world, Domtar is driven by a commitment to turn sustainable wood fiber into useful products that people rely on every day. Domtar operates pulp and paper mills and personal care facilities in the U.S., Canada, Spain, and Sweden. In the U.S. we operate in the following states: Arkansas, Illinois, Kentucky, Georgia, Michigan, Missouri, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Texas and Wisconsin.

Our Ashdown Mill, located in Ashdown, Arkansas, is one of the largest of Domtar's thirteen pulp and paper operations in North America. We are the largest employer in Ashdown providing about 850 local jobs and providing significant economic support for the local community. Ashdown's pulp and paper products are sold into global markets competing with low cost producers from other jurisdictions. Due to the continued decline in paper markets, the Ashdown Mill has recently undergone a major manufacturing process change with the conversion of a paper machine to manufacture fluff pulp. While the Ashdown Mill self-generates much of our manufacturing energy needs using renewable biomass and combined heat and power, we are still a net purchaser of electricity from our local utility.

Since the Ashdown Mill operates in highly competitive global markets, we continually look for ways to manage costs. As a large ratepayer, we are concerned our electricity costs could increase and our manufacturing costs could also increase due to approaches selected to address Regional Haze requirements for the 2008 to 2018 planning period and beyond.

The Regional Haze visibility program differs from most Clean Air Act programs in its focus on aesthetic rather than human health concerns. The Arkansas SIP proposal addresses Regional Haze requirements for sulfur dioxide and particulate matter at Arkansas power plants, evaluates controls necessary for ensuring reasonable progress toward natural visibility conditions, and sets reasonable progress goals for the first planning period ending in 2018. The SIP proposal also establishes a long-term strategy for improving visibility.

In January 2017, U.S Environmental Protection Agency (EPA) finalized amendments to The Requirements for State Plans for the Protection of Visibility. In this final rule, EPA changed requirements states must meet for the reasonable progress goals in the second and subsequent implementation periods. These changes were described as clarifications and streamlining of the visibility program. However, many of these revisions expand the scope of the program, adversely effects individual sources, and add significant burden to states. In addition, these changes can lead to certain stationary sources being targeted, resulting in competitive imbalance and market distortions. In the end, these so-called "clarifications" will cause states to "re-tool" the Regional Haze Program.

Several entities petitioned EPA to reconsider the 2017 final rule. The rule also is being legally challenged. EPA recently announced its decision to revisit aspects of the 2017 Regional Haze amendments and intends to commence notice and comment rulemaking to address the final rule.

Given the uncertain fate of the 2017 final rule and the likelihood that some or most of the rule may change, it is premature for Arkansas to rely on aspects of this rule and/or draft guidance for the proposed SIP. Domtar is concerned that moving forward now will only result in being required to withdraw the SIP changes and redo the effort to conform to the revised rule. This stop/start approach is not likely to achieve results helpful to the Arkansas business community and the residents of Arkansas.

In the proposed SIP, ADEQ is taking a position that is inconsistent with the position Arkansas has taken in challenging the EPA Arkansas Regional Haze Federal Implementation Plan. Since Arkansas' Class I areas are already meeting and exceeding the uniform rate of progress (URP) or "glide path" for this 1st planning period, no reasonable progress analysis is needed. Moreover if recent trends in actual observation data continue, the 2064 goals will be achieved well in advance. ADEQ's proposed approach for reasonable progress is inappropriate and not necessary and furthermore sets a bad precedent that may limit the State's flexibility for future planning periods. While Domtar is not directly affected by ADEQ's reasonable progress evaluation proposal for the 1st planning period, we will be indirectly affected through an inevitable increase in electric power prices. As such, Domtar is concerned with ADEQ's approach in the proposed SIP. ADEQ should continue to find that a reasonable progress assessment to evaluate controls is not necessary since Arkansas will achieve reasonable progress and is meeting its glide path with no additional controls needed.

Domtar requests ADEQ revise portions of the proposed SIP that are inconsistent with positions taken by Arkansas in challenging the EPA's Arkansas regional Haze Federal Implementation Plan and that rely on draft guidance and/or the challenged 2017 rule.

Thank you for the opportunity to comment on the proposed rule. Please contact me if you have any questions about these comments or would like to further discuss.

Sincerely,

Re: Comments on Proposed Revisions to Arkansas Regional Haze State Implementation Plan (AR RH SIP)

Dear Ms. Treece:

The Energy and Environmental Alliance of Arkansas (“EEAA”) is an ad-hoc association of Arkansas’ investor-owned, municipal, and independent electric utilities and other energy companies formed to advocate, communicate and encourage energy and environmental policies that promote sound and predictable regulation of Arkansas’ utility industry, and support an economically viable and environmentally secure future for all Arkansans, including access to reliable and affordable energy resources.

Members of EEAA own part or all of several facilities directly impacted by the Draft Revisions to the State Implementation Plan (“SIP”) related to Regional Haze. In particular, EEAA members own or operate the Flint Creek Electric Power Plant (“Flint Creek”), the White Bluff Steam Electric Station (“White Bluff”), the Independence Steam Electric Station (“Independence”), and the Lake Catherine Plant (“Lake Catherine”). Accordingly, EEAA is critically interested in the development of the State’s Regional Haze SIP, and respectfully submits the following comments.

On October 31, 2017, the Arkansas Department of Environmental Quality (“ADEQ”) publicly released draft revisions to certain disapproved portions of the 2008 Arkansas Regional

Haze State Implementation Plan (“SIP”) (“Draft SIP”). The Draft SIP addresses certain best available retrofit technology (“BART”) and reasonable progress controls for Arkansas sources during the first planning period. If the Draft SIP is approved by EPA, the applicable BART and reasonable progress requirements in the Arkansas Regional Haze Federal Implementation Plan (“Final FIP”) would be withdrawn.¹ 81 Fed. Reg. 66,332 (Sept. 27, 2016).

Arkansas is already below the glidepath for the first planning period, so no reasonable progress analysis is necessary. ADEQ takes inconsistent positions in its Petition for Reconsideration of the FIP and the Draft SIP regarding the need for a reasonable progress analysis. Arkansas is already below the glidepath for the first planning period, so no reasonable progress analysis is necessary. Arkansas appealed the FIP based on the imposition of controls even though the State was already meeting the reasonable progress goals EPA established in the FIP. The *necessity* of controls for achieving visibility improvements at or below the glidepath is a threshold issue when addressing reasonable progress. The CAA requires implementation plans to “contain such emission limits, schedules of compliance and other measures as may be **necessary** to make reasonable progress.” See 42 U.S.C. § 7491(b)(2) (emphasis added). The State position should remain that no controls are necessary where evidence shows that Arkansas will achieve reasonable progress without any controls.

In addition, the Regional Haze program is intended to be a gradual phasing in of measures to improve visibility, and does not demand the best controls for all sources. Conducting an unnecessary reasonable progress analysis now could also limit ADEQ’s ability to take advantage of technological developments, improvements in economic performance, and other improvements in subsequent planning periods. It would thus become more likely that unnecessarily stringent and costly controls would be imposed upon Arkansas sources without measurable benefits.

ADEQ should take full advantage of available regulatory flexibility. EPA’s guidance makes it clear that states have flexibility in evaluating the statutory factors and

¹ In 2016, EPA promulgated the FIP to address the disapproved portions of Arkansas’ regional haze plan.

including other factors determined to be relevant. “In determining reasonable progress, CAA § 169A(g)(1) requires States to take into consideration a number of factors. However, you have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant.” *See Reasonable Progress Guidance at 5-1.*² ADEQ’s focus on a source-specific reasonable progress analysis ignores “the implication of compliance costs to the health and vitality of industries within a state.” Reasonable Progress Guidance at 5-1. Rather than perform a source-specific reasonable progress analysis under the time constraints associated with this SIP development period, ADEQ and sources within the state should be given an opportunity to consider more broadly the complete set of relevant factors to be considered, and allowed to await resolution of the challenges to EPA’s 2017 state planning requirements.

ADEQ should consider all relevant specific operational information presented by a Permittee. ADEQ failed to utilize critically important specific facility information provided by a Permittee (Entergy) regarding the planned operating conditions of permitted facilities. In particular, Entergy has stated it has planned a specific cease to use coal date and agreed to accept an enforceable restriction in that regard. However, this key operational fact was not considered by ADEQ in analyzing the cost-effectiveness of certain control options. ADEQ must consider all available information provided in developing its Long-Term Strategy, including planned controls, and planned retirement dates. 40 C.F.R. §§ 51.308(d)(3). The measures must be made enforceable to make the SIP durable and less susceptible to legal challenge.

ADEQ should avoid re-opening already approved SIP provisions. ADEQ is attempting to rescind and re-propose certain limits that have were approved and accepted by EPA in the initial SIP submission. Those previously approved limits are already effective and are included in the Title V permits. The act of rescinding and re-proposing already approved

² U.S. EPA, *Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program* (June 1, 2007) (hereinafter Reasonable Progress Guidance”). Available at: https://www3.epa.gov/ttn/naaqs/aqmguide/collection/cp2/20070601_wehrum_reasonable_progress_goals_reghaze.pdf

February 2, 2018

limits, could have the unintended side-effect of making them susceptible to a second round of challenges by parties seeking to oppose them.

EEAA appreciates the opportunity to comment on the Draft SIP. The final SIP will impact Arkansas utilities, other industries, and citizens for decades to come. EEAA urges ADEQ to broadly consider all relevant factors in determining reasonable progress, avoid unnecessary controls, take into account all relevant facility information provided by permittees, and avoid re-opening previously approved SIP provisions. These steps should assist ADEQ in developing a final SIP that is legally supportable and that provides regulatory certainty. EEAA Members appreciate the progress that ADEQ has made in helping return this program to the State of Arkansas and its citizens.

Sincerely,

Subject: Haze Plan
Date: Friday, January 19, 2018 7:38:45 AM

Tricia Treece, Office of Air Quality, ADEQ

Ms Treece,

I would like to submit my comments to the requirement of the 1999 Clean Air Act that requires states to take action to reduce smog/haze in certain parks and wilderness.

First, why are we so far behind? Does Arkansas prefer to ignore responsibility? Arkansas was once a leader in environmental quality why have we now become an inadequately educated environmental agency that hasn't begun with the basic plan and already implemented our smog and haze reduction where we know it exists. How many of our streams and lakes have high levels of coal particulates making it unsafe to eat the fish? I have watched this list grow yearly, it is time to act and I hope you will quickly. How much does Arkansas receive yearly from EPA, 60 plus million?

Arkansans depend on air and the quality of the air reflects the quality of the health of the citizens and those that visit. Pollutants lift, drift, rain down or settle with cooler air temperatures into valleys and lands that may be inside not only national parks, but state parks, streams, lakes and rivers and all lands.

I ask that ADEQ revise its proposed plan to include scrubbers on White Bluff and Independence, and to retain source-specific NOx limits instead of the trading program.

The last few years have shown me Arkansas has lagged in its support of clean water and air quality. I think this directly relates to the health of its citizens. Please take into account the highest quality of education and utilize what knowledge we have to make a future that can make a difference in the lives of all Arkansans.

RE: Comments on the State of Arkansas's "Revisions to the Arkansas Regional Haze State Implementation Plan" prepared by the ADEQ – October 2017

Dear Ms. Treece:

The Louisiana Electric Utility Environmental Group ("LEUEG") hereby submits the following comments related to the draft revisions to the Arkansas Regional Haze State Implementation Plan ("SIP"). LEUEG appreciates the opportunity to provide these comments to the Arkansas Department of Environmental Quality ("ADEQ") and requests that ADEQ include this letter in the administrative record for this regulatory evaluation.

On October 31, 2017, ADEQ released for public review a draft revision to certain disapproved portions of the 2008 Arkansas Regional Haze SIP (the "Proposed SIP"). The Proposed SIP addresses best available retrofit technology ("BART") and reasonable progress controls for sources in Arkansas for the first planning period. It is our understanding that EPA's approval of the Proposed SIP will result in the withdrawal of the applicable BART and reasonable progress requirements in the Arkansas Regional Haze Federal Implementation Plan ("Final FIP") promulgated by the U.S. Environmental Protection Agency ("EPA") in 2016. *See*, 81 Fed. Reg. 66,332 (Sept. 27, 2016).

As discussed in the comments below, LEUEG believes that ADEQ should amend the Proposed SIP to improve and clarify certain sections set forth therein.

Comment 1 – ADEQ is not legally required to conduct a reasonable progress analysis on a source-specific basis and, for this Proposed SIP, should not do so. Instead, other relevant factors should be considered by ADEQ in the Proposed SIP to justify reasonable progress.

Section 169A(a) of the federal Clean Air Act sets forth statutory requirements relating to the protection of visibility in federal Class I areas, including directing EPA to "promulgate regulations to assure reasonable progress toward meeting the national goal" of prevention of

visibility impairment. *See*, 42 U.S.C. § 7491(a). CAA §169A(b) further directs SIPs “to contain such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal specified in [CAA §169A(a)], including ... a long term strategy ... for making reasonable progress toward meeting the national goal specified in [CAA §169A(a)].” With respect to reasonable progress factors, CAA §169A(g)(1) states:

in determining reasonable progress there shall be taken into consideration the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements.

42 U.S.C. § 7491(g)(1). To comply with this mandate, EPA established regulations and guidance relating to reasonable progress, including a document entitled “Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program,” dated June 1, 2007 (EPA’s “*Reasonable Progress Guidance*”). This guidance document, which applies to the first planning period, is clear that the four statutory factors set forth above (*i.e.*, cost of compliance, time necessary for compliance, energy and non-air impacts, and remaining useful life) must be considered by states in a reasonable progress analysis. However, when determining reasonable progress, the Reasonable Progress Guidance is also clear that states have the authority to consider other relevant factors. For instance, Section 5.0 of EPA’s reasonable progress guidance concerning applying the statutory factors to potentially affected stationary sources states:

In determining reasonable progress, CAA § 169A(g)(1) requires States to take into consideration a number of factors. However, you have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant.

Reasonable Progress Guidance, p. 5-1. Section 4.2 of the same guidance further states:

After determining the amount of emissions reductions of visibility impairing pollutants that may be expected from implementation of other CAA programs, you will be ready to identify any additional measures that are reasonable. The [Reasonable Haze Rule] gives States wide latitude to determine additional control requirements, and there are many ways to approach identifying additional reasonable measures; however, you must at a minimum, consider the four statutory factors. Based on the contribution from certain source categories and the magnitude of their emissions you may determine that little additional analysis is required to determine further controls are not warranted for that category. As discussed further in section 5, you have considerable flexibility in how you take these factors into consideration.

Id., p. 4-2 (emphasis added).

Based on the foregoing, ADEQ is not limited to consideration of the four factors mandated by the CAA on a source-specific basis. Instead, ADEQ is specifically authorized by EPA's guidance to consider other relevant factors. In addition, there is no requirement that the analysis mirror a best available retrofit technology ("BART") analysis. In fact, EPA confirmed this in a 2006 guidance document in which it states: "The reasonable progress demonstration ... is not a source-specific demonstration like the BART assessment." Rather, the "reasonable progress demonstration involves the test of a strategy." *See*, EPA's "Additional Regional Haze Questions," Q.1, p. 9 (Sep. 27, 2006 Revision). As discussed below, LEUEG believes it is appropriate for ADEQ to consider other factors to satisfy its reasonable progress goals in the Proposed SIP.

Comment 2 – Because Arkansas is already meeting its reasonable progress goals, a “source-specific” reasonable progress analysis is not required and should not be included in the Proposed SIP.

Based on our review of the Proposed SIP and supporting data, Arkansas is already meeting its reasonable progress goals ("RPGs") for the first planning period and is requiring eligible sources to meet BART limits. For this reason, no additional controls are necessary to assure reasonable progress for Arkansas' first planning period.

The threshold issue when addressing reasonable progress is whether further actions in addition to other requirements that will reduce emissions, such as BART, are *necessary* to ensure that visibility improvement is continuing on or below the glide path. As noted in Comment 1, the Clean Air Act states that implementation plans must "contain such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress." *See*, 42 U.S.C. § 7491(b)(2) (Emphasis added). Consistent with this mandate, EPA's *Reasonable Progress Guidance* makes clear that reasonable progress controls may not be necessary in the first planning period. In Section 4.1 of the guidance, EPA states:

Given the significant emissions reductions that we anticipate to result from BART, the CAIR, and the implementation of other CAA programs, including the ozone and PM_{2.5} NAAQS, for many States this will be an important step in determining your RPG, and it may be all that is necessary to achieve reasonable progress in the first planning period for some States.

Id., p. 4-1. In addition, EPA states the following in Section 1.2 addressing the meaning of the term "reasonable progress goal":

In deciding what amount of emissions reduction is appropriate in setting the RPG, you should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for you to defer reductions to later planning periods in order to maintain a consistent glidepath toward the longterm goal.

Id., p. 1-4. Thus, ADEQ should require additional controls only if further action is determined to be *necessary* for reasonable progress. Based on our review of the Proposed SIP and supporting documents, ADEQ has not made this determination. Rather, for the first planning period, controls beyond BART are not necessary for reasonable progress based on the current air quality in Arkansas's Class I areas and supporting air quality data. Visibility improvement in Arkansas's Class I areas is on such an accelerated pace that the rate of progress towards the visibility goal exceeds the Uniform Rate of Progress ("URP") necessary to remedy visibility impairment at Caney Creek Wilderness Area ("CACR") and Upper Buffalo Wilderness Area ("UPBU") by 2064. Arkansas already has achieved visibility improvements in its Class I areas that surpass the RPGs in the Final FIP for the first planning period, rendering the imposition of additional reasonable progress controls unnecessary for the first planning period.

Analysis by ADEQ demonstrated that visibility in Caney Creek and Upper Buffalo very likely will meet the levels EPA ultimately finalized as the RPGs for 2018, even in the absence of additional controls. *See*, Arkansas Department of Environmental Quality, *State Implementation Plan Review for the Five-Year Regional Haze Progress Report*, at 55-56 (May 2015). EPA also recognized in its Proposed FIP that Arkansas' Class I areas were projected to meet the URPs for the first planning period, even without controls on stationary sources. These predictions have been confirmed by more recent IMPROVE data for 2016, which show that visibility measurements in both CACR and UPBU were better than the RPGs in the FIP.

Because Arkansas is already meeting its reasonable progress goals, additional controls are unnecessary and should not be required in the Proposed SIP. If ADEQ intends to require a source-specific reasonable progress analysis, this determination should be fully justified by the agency in the final SIP.

Comment 3 – ADEQ is unnecessarily taking inconsistent positions in this Proposed SIP and its *Petition for Reconsideration* of the Final FIP promulgated by EPA in 2016.

In addition to being legally unnecessary, ADEQ's assessment of reasonable progress control options despite Arkansas' substantial progress toward the national visibility goal is counter to its own pending petitions for reconsideration and review of the Final FIP. In its administrative petition requesting that EPA reconsider the Final FIP, ADEQ urges EPA to "reconsider whether controls on Independence are necessary under the Clean Air Act because 2015 monitoring data shows that Arkansas is currently meeting the reasonable progress goals set in the FIP and will continue to meet those goals for the remainder of the first planning period." Administrative Petition for Reconsideration and Request for Stay of ADEQ at 3 (Nov. 23, 2016). Similarly, in its opening brief in the litigation challenging the Final FIP, ADEQ argues that "[t]he Final [FIP] should be vacated because EPA ignored evidence that Arkansas would achieve reasonable progress—and natural visibility before 2064—without any additional controls." Opening Br. for Arkansas at 36, *Arkansas v. EPA*, No. 16-4270 (8th Cir.). These assertions are inconsistent with ADEQ's interpretation of the reasonable progress requirements of the CAA. In fact, ADEQ is arguably requiring in the Proposed SIP what it is challenging EPA for doing in the Final FIP.

It is also possible that ADEQ's current approach could limit its ability to change course in the second and subsequent planning periods. An EPA approval of ADEQ's decision to perform an unnecessary reasonable progress analysis may limit ADEQ's discretion if it decides not to perform a reasonable progress analysis under similar conditions in the future. In this scenario, ADEQ might be forced to assess reasonable progress controls even if visibility *exceeds* the goals, increasing the likelihood that unnecessary controls would be imposed upon Arkansas stationary sources.

In light of the foregoing, ADEQ should revise the Proposed SIP to eliminate the four-factor analysis and determine that no controls are necessary for the evaluated utilities given the observed visibility improvements at Arkansas's Class I areas. Based on the most recent air quality monitoring data, no further measures are *necessary* for Arkansas to make reasonable progress toward the Regional Haze Program national goal in the first planning period, so a reasonable progress analysis is not required. Such a determination would be consistent with EPA's guidance that reductions may be deferred "to later planning periods in order to maintain a consistent glidepath toward the long-term goal." *Reasonable Progress Guidance*, p. 1-4.

Ms Teece,

Thank you for your work serving our great state.

Please do not revise ADEQ's proposed plan to include scrubbers on White Bluff and Independence, nor retain source-specific NOx limits instead of the trading program.

The people of AR love our natural state but they also love having a job. I believe ADEQ is doing an increasingly better job striking that difficult balance.

Sincerely,

Bart Hester

Tricia Treece, Office of Air Quality, ADEQ

Ms Treece,

I would like to submit my comments to the requirement of the 1999 Clean Air Act that requires states to take action to reduce smog/haze in certain parks and wilderness.

First, why are we so far behind? Does Arkansas prefer to ignore responsibility? Arkansas was once a leader in environmental quality why have we now become an inadequately educated environmental agency that hasn't begun with the basic plan and already implemented our smog and haze reduction where we know it exists. How many of our streams and lakes have high levels of coal particulates making it unsafe to eat the fish? I have watched this list grow yearly, it is time to act and I hope you will quickly. How much does Arkansas receive yearly from EPA, 60 plus million?

Arkansans depend on air and the quality of the air reflects the quality of the health of the citizens and those that visit. Pollutants lift, drift, rain down or settle with cooler air temperatures into valleys and lands that may be inside not only national parks, but state parks, streams, lakes and rivers and all lands.

I ask that ADEQ revise its proposed plan to include scrubbers on White Bluff and Independence, and to retain source-specific NOx limits instead of the trading program.

The last few years have shown me Arkansas has lagged in its support of clean water and air quality. I think this directly relates to the health of its citizens. Please take into account the highest quality of education and utilize what knowledge we have to make a future that can make a difference in the lives of all Arkansans.

I understand the State of Arkansas is suing to stop the EPA plan requiring White Bluff and Independence coal burning power plants to install modern pollution control. And with the support of ADEQ, intends to replace it with a weaker plan. I cannot understand how an agency whose reason for being is largely to protect the citizens of the state (and those in other states as well) could support such a measure. If I'm misunderstanding the gist of the argument for replacing a strong plan with a weaker one, please inform me.

Mr. Beverly C. D. Edwards, Jr.
2905 West Highway 88
Oden, Arkansas 71961

January 18, 2018

Arkansas Department of Environmental Quality

Dear ADEQ:

A massive amount of regional haze in Arkansas is caused by exhaust pollution from coal fired electric power plants in Arkansas. Coal should be eliminated as a fuel in our electric power plants. Natural gas, wind turbine farms and solar farms should replace coal as the fuel to be used.

Sincerely,

Bev Edwards

Date: Friday, January 19, 2018 1:22:43 PM

ADEQ,

The fact that this department is even considering not doing everything it can to make our coal plants as clean as possible is ridiculous. Your website states "We protect, enhance and restore the natural environment for the well-being of all Arkansas." However, the plan you have chosen to pursue directly contradicts your mission for the protection of Arkansas.

Scrubbers should be required at all plants, and the fact that you are even considering not installing them is shameful. There is no reason not to make the air as clean as possible. With the national government failing on all aspects to protect the environment, and even going as far as reversing regulations in the name of increasing profits for a few CEO's, it falls to the state and local governments to do everything they can to help protect our natural resources.

It is also critical to ensure that there are source-specific NOx limits are in place in order to protect those living near the polluting plants.

This department has repeatedly ignored the requests and desires of the people in its decisions on environmental regulations. It is time for you to start moving in the right direction and start protecting the natural state. Listen to the will of the people and do what is best for everyone.

Protect this land we all call home,

Garrett Lampson

I would ask that you reread your mission statement. I also ask that you drop your opposition to reducing smog in our parks. My tax dollars going into your budget of over \$4 mil need to be allocated to doing more to reduce this problem. I am also wondering why you seem to be in Entergy's back pocket. They are one of the biggest producers of industrial pollution. This is a serious problem and if ADEQ doesn't give serious consideration to clean air, this will be brought to the attention of the media. I, for one, do not want my tax dollars going to an ineffective organization.

Sincerely,
Gladys Sutliff

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Keaton Smith

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

William Hiers

Dear Arkansas Department of Environmental Quality,

Even Exxon, China, India and are divesting from coal to safe renewables. We all know coal is dead. We need to retrain the coal workers to make solar panels and wind turbines. Do the right thing. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Alice Ault

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

So the "Natural State" is working towards a new motto - the "Toxic State". That should really encourage businesses to invest in doing business in Arkansas. I'm sure it'll be quite the enticement for corporations and employees alike.

And I'm sure our healthcare system in America will take care of these issues without any problems.

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Anne Philipps

Dear Arkansas Department of Environmental Quality,

Arkansas...the Natural State...will no longer BE the clean, pristine State the attracts tourists from all over the world as it does now. I am appalled that this would be done in such an allegedly Christian state,..to do something so harmful to all life.

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Ben Sandmon,usn Ret.

Dear Arkansas Department of Environmental Quality,

Please stand strong for clean air for your customers. As a major corporation, please respect the planet and its resources. In addition, please move forward with renewable energy in your strategic planning for your corporation. We, as a progressive nation along with all major world leaders, are concerned about climate change and the need to become diverse in our energy resources.

Dear Arkansas Department of Environmental Quality,

Please think of the environment(s) and how this is putting you - your families and many of the rest of us in health dangers. Demand to work with your State and local areas to get the most up to date equipment and work with only the plant facilities that do so. Kindest regards,
Betsy

Dear Arkansas Department of Environmental Quality,

As an Arkansan with family in St. Louis, I am disgusted by Entergy's management of these coal plants and their effect on the air. There is no good reason for Arkansan energy sources to be considered the dirtiest.

Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Brad Catoe

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Wednesday, January 17, 2018 10:59:19 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Caroline Pufalt

Dear Arkansas Department of Environmental Quality,

We need to make coal clean, or, it will need to go! Consumers would pay a few more cents to breath fresh air. But the technology needs to be used.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

Dear Arkansas Department of Environmental Quality,

Entergy is also much more expensive than our rural coops. They are pocketing a huge amount of profit. This profiteering on the backs of their customers and their neighbors is unacceptable. Clean it up NOW. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Tuesday, December 19, 2017 10:08:38 AM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Chris Mihill

Dear Arkansas Department of Environmental Quality,

As someone with family members in both AR and MO, this is extremely upsetting. If you're going to continue to burn dirty coal rather than converting to cleaner technologies, at least add catalytic reduction to your power plants!

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Curtis Stuck

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

David Nilles

Dear Arkansas Department of Environmental Quality,

Please consider the people impacted by your actions -- or inactions -- and make the responsible, morally correct decision to enforce regulations that reduce or mitigate emissions. Thank you.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 2:04:50 PM

Dear Arkansas Department of Environmental Quality,

Please require cleaner air standards so I, and many other asthma sufferers, will be able to breathe!!!
In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Dorothy Funk

This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Elyse Partee

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

Why should my grandchild's very breath subsidize a coal plant's bottom line? Her asthma is not her fault---it's yours, Entergy. Shame on your criminality! Try finding some morals and ethics in your company.

Let's preserve Arkansas' beauty and natural resources by NOT allowing companies to muddy up our skies and water!

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Gamin Davis

Dear Arkansas Department of Environmental Quality,

I have lived in Arkansas for the past 30 years. I am appalled to know that you have used the money I pay Entergy for services every month has not been used to better the life and welfare of Arkansas. I beg you to end coal pollution and smog that harms the Natural State and its inhabitants. Clean up the emissions from the Entergy plants!

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 11:19:12 AM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Gordon Messling

Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Holly Goodrich

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

James Phelps

Dear Arkansas Department of Environmental Quality,

I really don't think Arkansas can truthfully call itself The Natural State while outgassing coal burning pollution. I grew up in Arkansas and I don't want pollution to harm me and my family, the wilderness areas nor citizens of our neighboring state Missouri. Let's focus on clean alternative energy!

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Jeff Albers

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Joe Boersma

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Wednesday, January 17, 2018 10:43:38 PM

Dear Arkansas Department of Environmental Quality,

Solar and Wind power are better options, and less harmful on the environment.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Josh Kuykendall

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Karen Gerot

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

I live in the other direction from St. Louis. I live in South Arkansas. I moved here 4 years ago from Central Mississippi. I use a CPAP machine nightly. One filter in my CPAP machine would begin to look dirty in Mississippi after 6 months use. Another after a year. Here in South Arkansas, they look dirtier after one weeks use than what I just wrote about my Mississippi experience. Also, I am a gardener. The soil here is different and for awhile I couldn't remember what it reminded me of. It finally dawned on that the soil in South Arkansas reminds me of the ash heaps in Saltville, Virginia, that are now an EPA Superfund Site.

And, I am 60 years old and used to teach. When I visit my granddaughter's schools, I am always astounded at what to me seems like a very high number of special needs children. I am worked in schools in towns and counties with a similar number of people, but which did not have this many special needs students. Also, I see larger numbers of special needs adults that I am used to from living in cities outside of Arkansas. There seems to be something very very wrong here and I suspect it is in the environment. This is a terrible strain on individuals, their families and government programs like Social Security Disability. Taking care of our environment is the most important issue to me. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Kathy Smith

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Kim Lovely

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Lauren Daniel

Dear Arkansas Department of Environmental Quality,

The health of Arkansans and Missourians is at stake.

It is the duty of the coal plants to have rigorous cleanup plans that actually protect the residents of Arkansas and Missouri. Take the responsible course of action!

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Lynne Clifton

Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Mark Mcandrew

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 1:03:41 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Mary Kriegshauser

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Wednesday, January 17, 2018 10:37:06 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Michelle Schultz

The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Nicole Roberts

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Paul Ohlendorf

Dear Arkansas Department of Environmental Quality,

Over my many years of teaching high school, I have seen the number of students suffering from asthma rise dramatically, especially in urban areas. This is unacceptable and you have the means to correct the situation. Act on behalf of people rather than profits.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Thursday, January 18, 2018 1:27:27 PM

Dear Arkansas Department of Environmental Quality,

Like many others, I suffer from asthma. Pollutants mean that I rarely get a break from breathlessness. Pollution kills slowly. I am dying in St Louis.
In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Rebecca Richardson

Dear Arkansas Department of Environmental Quality,

Unbelievable that this technology has not been already required. Renewable energy and end-user conservation alternatives should be pursued as well.

Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Robert Pankratz

Dear Arkansas Department of Environmental Quality,

It is far past time for clean energy - wind and solar. Let's embrace the 21st century, not go backwards. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Sandi Walters

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Wednesday, January 17, 2018 6:04:07 PM

Dear Arkansas Department of Environmental Quality,

We must be proactive in protecting the air quality and water quality.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Sherlene Watkins

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Steve Hooper

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Terry Kippenberger

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Thursday, January 18, 2018 12:44:28 AM

Dear Arkansas Department of Environmental Quality,

Xcel Energy in Colorado got 96 bids at a median price of \$18.10 per MWH for over 42 GW of wind alone and 11 bids on wind plus battery storage at a median price of \$21 per MWH for a total of 5.7 GW. The incremental increase from the storage is less than the cost of a gas turbine peaker plant. This is presumably due to the extremely low cost of electricity from wind in Colorado, while natural gas peakers are the source of the most expensive marginal electricity prices because of the inefficiency of peakers in burning NG. For solar PV, Xcel got 152 bids at a median price of \$29.50 per MWH for a total of almost 30 GW of total bids, and 87 bids on solar PV and battery storage at a median price of \$36 per MWH for almost 17 GW of total bids. The last are similar to merely operating the dirty coal plants at White Bluff and Independence. Arkansas has better solar resources than Colorado. The wind plus storage bids are cheaper than the operating cost of the White Bluff coal plant. SW EPCO shows that Arkansas utilities can access some of the cheapest wind electricity in the world with Capacity Factors above 50%.

SWEPCO to save customers over \$5 billion by buying 1.4 GW of 50% CF wind power from Oklahoma. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Dear Arkansas Department of Environmental Quality,

In addition, Xcel Energy in Colorado got 96 bids at a median price of \$18.10 per MWH for over 42 GW of wind alone and 11 bids on wind plus battery storage at a median price of \$21 per MWH for a total of 5.7 GW. The incremental increase from the storage is less than the cost of a gas turbine peaker plant. This is presumably due to the extremely low cost of electricity from wind in Colorado, while natural gas peakers are the source of the most expensive marginal electricity prices because of the inefficiency of peakers in burning NG. For solar PV, Xcel got 152 bids at a median price of \$29.50 per MWH for a total of almost 30 GW of total bids, and 87 bids on solar PV and battery storage at a median price of \$36 per MWH for almost 17 GW of total bids. The last are similar to merely operating the dirty coal plants at White Bluff and Independence. Arkansas has better solar resources than Colorado. So, the wind plus storage bids are cheaper than the operating cost alone of the White Bluff or Independence coal plants. SWEPCO proved that Arkansas utilities have access to some of the cheapest and most reliable wind electricity in the world with Capacity Factors above 50%.

Also, SWEPCO reports that they are going to save their customers over \$5 billion by buying 1400 MW of 50% CF wind power from Western Oklahoma. This size is comparable to each of the double units White Bluff and Independence.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. Dear Arkansas Department of Environmental Quality,

We as human beings are now at a particular time in our history to make decisions that will guarantee whether or not we will have a future at all. Those of us with the power to make changes that will save lives still seem more preoccupied with the kind of profiteering off of toxic energy sources that will ultimately poison our planet while simultaneously destroying the resources (air/food/water) that no living being can survive without. When smoke and toxic fumes dissipate into our air...It is still there. When oil, coal ash, fracking chemicals, and nuclear waste leaks into our oceans, lakes, rivers, and groundwater...It is still there. When any of these toxins seep into our earth...It is still there.

"Out of sight" may mean "out of mind" to those lacking common sense, but the more we pour poisons into our environment, the more we will feel and see the effects...and ultimately all life will end without a sustainability agenda that all humans must honor. The path we are already on leads only towards a slow suicide on a planetary scale...and it picks up speed every day we ignore the truth.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Tommi West

Re: Comments of Southwestern Electric power Company on
Proposed Revisions to the Arkansas Regional Haze SIP
For the 2008 – 2018 Planning Period (October 2017)

Dear Ms. Treece:

Southwestern Electric Power Company (SWEPCO), an operating company of the American Electric Power system, appreciates the opportunity to participate in the development of revisions to the Arkansas Regional Haze State Implementation Plan (RH SIP) for the first planning period from 2008 to 2018. SWEPCO owns and operates the Flint Creek Plant, a source regulated in this first planning period, and other sources that may be affected in future planning periods. Therefore, SWEPCO has a vital interest in the application of sound principles to evaluate the measures that might be required to achieve visibility improvements, and has supplied technical and other information to help inform ADEQ's plan development process.

The RH SIP submitted by the Arkansas Department of Environmental Quality (ADEQ) in October will allow the state to resume full control of the planning and administration of this program that will gradually improve visibility in some of the most scenic places in the country. ADEQ is best equipped to consider how to make measureable and reasonable progress toward these goals by considering the key characteristics of individual facilities, including applicability of specific technologies, economic considerations, and site-specific characteristics.

ADEQ has already successfully revised the best available control technology (BART) requirements for nitrogen oxides (NO_x) by gaining approval to rely on compliance with existing requirements under the Cross-State Air Pollution Rule to provide greater emission reductions than would otherwise be achieved through the application of source-specific BART controls. Notice of U.S. EPA's approval of that plan should be published in the *Federal Register* shortly. This revision allows BART-eligible sources to comply in an extremely cost-effective manner by making emission reductions where they are most economic, and including a wider group of facilities within the emission reduction program.

BOUNDLESS ENERGY

SWEPCO appreciates ADEQ's willingness to consider all of the technical information submitted to U.S. EPA in support of the BART determination made at the Flint Creek Plant for sulfur dioxide (SO₂). This information amply supports ADEQ's determination that the equipment already installed at Flint Creek satisfies the requirements of the regional haze program at this facility, and that achieving an SO₂ emission rate of 0.06 pounds of SO₂ per million British thermal unit (#/mmBtu) will reduce visibility impacts at Class 1 areas in Arkansas. These measures, in combination with the state-of-the-art technologies and controls already in place at the John W. Turk, Jr. Power Plant and the Mattison Power Plant, allow SWEPCO to continue providing affordable and reliable electric service to customers in Arkansas in compliance with all applicable environmental standards.

SWEPCO would like to comment on two aspects of the plan that create some concerns. First, ADEQ plans to rely on administrative consent orders to establish emission limitations for the BART-eligible facilities, rather than modifying the rules in APC&EC Regulation No. 19 Chapter 15. SWEPCO supports the use of administrative orders negotiated with the facilities as an efficient way to adopt requirements that are not currently effective. However, ADEQ proposes to repeal currently effective requirements for particulate matter that have already been approved by U.S. EPA as part of the Arkansas SIP, and replace them with identical requirements under the administrative orders. There is no need for such action, and it potentially exposes ADEQ and the facilities to legal challenges when no change is occurring.

Second, SWEPCO has reviewed the comments prepared by the Arkansas Environmental Federation, and the Energy and Environmental Association of Arkansas, and encourages ADEQ to reconsider whether any reasonable progress analysis is necessary as part of the first planning period submission. The State of Arkansas and other parties challenged U.S. EPA's aggressive interpretation of these requirements in the litigation over the federal implementation plan, and have also opposed regulatory changes that would limit state discretion. Given the excellent progress Arkansas has made in improving visibility, the better course would be to defer this analysis to the next planning period in 2021.

If you have any questions concerning these comments, please contact Brian Bond at (618) 673-3595. We appreciate the opportunity and the efforts made by ADEQ to facilitate the return of this program to the state.

Very truly yours,

Janet Henry
Deputy General Counsel
American Electric Power Service Corporation

Re: Revisions to the Arkansas State Implementation Plan: Proposed
Regional Haze SIP Revision for 2008-2018 Planning Period, October
2017.

Dear Ms. Treece:

This firm represents the Arkansas Affordable Energy Coalition (“AAEC”). Attached please find AAEC’s comments on the Arkansas Department of Environmental Quality’s (“ADEQ”) Proposed Revisions to the Arkansas State Implementation Plan, Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017 (the “Phase II RHR SIP Revision”).

As explained in more detail in the attached comments, the AAEC is a coalition that includes electric consumers, and associations of electric consumers, that purchase power from electric utilities that own and operate electric power plants

located in the State of Arkansas that are affected by the Phase II RHR SIP.

AAEC appreciates the opportunity to submit these comments. Please let me know if you have any questions.

Sincerely,

A handwritten signature in blue ink, appearing to read "Mark Walters", with a stylized flourish at the end.

Mark Walters

COMMENTS OF THE ARKANSAS AFFORDABLE ENERGY COALITION

FEBRUARY 2, 2018

REVISIONS TO THE ARKANSAS STATE IMPLEMENTATION PLAN
REGIONAL HAZE SIP REVISION FOR 2008-2018 PLANNING PERIOD

ARKANSAS DEPARTMENT OF ENVIRONMENTAL QUALITY
OFFICE OF AIR QUALITY

OCTOBER 2017

The Arkansas Affordable Energy Coalition (“AAEC” or the “Coalition”) submits the following comments on the Arkansas Department of Environmental Quality (“ADEQ”) Proposed Revisions to the Arkansas State Implementation Plan, Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017 (the “Phase II RHR SIP Revision”).

AAEC is a coalition that includes electric consumers, and associations of consumers, that receive power from the electric power plants affected by the Phase II RHR SIP, namely Entergy’s White Bluff and Independence plants, and SWEPCO’s Flint Creek plant. For example, the Arkansas steel mills of AAEC members Nucor Corporation and Nucor-Yamato Steel Company (“NYS”) are significant customers of and members in the Mississippi County Electric Cooperative, Inc. (“MCECI”). MCECI is a member of Arkansas Electric Cooperatives, Inc. (“AECI”), which is a co-owner of the Independence, White Bluff, and Flint Creek plants. Much of the electricity purchased by the Nucor and NYS Arkansas mills comes from these three power plants. AAEC’s membership also includes Arkansas Electric Energy Consumers, whose members are large, industrial customers of Entergy Arkansas, Inc.

Although public utility plant owners and operators will be responsible initially for the cost of installing the pollution controls or taking other actions

required under the Phase II RHR SIP, under Arkansas law, such owners and operators are permitted to directly pass through and recover the costs and expenses of installing, operating, and maintaining pollution controls from electric utility customers and ratepayers, such as Nucor and other AAEC members, through electricity rates and tariffs filed with the Arkansas Public Service Commission. *See* Ark. Code Ann. §§ 23-4-501, -504 (authorizing an immediate utility rate surcharge to recover costs incurred by a utility to comply with environmental regulations). In addition, utility plant owners and operators must obtain regulatory approval from the Arkansas Public Service Commission and other authorities, and are permitted to recover from electric utility customers and ratepayers the cost of replacement power or capacity needed to replace the premature retirement of electric generating units, or the costs of switching fuel at such facilities. *See*, Declaration of Kurt Castleberry, January 11, 2018, ¶¶ 17-26 (copy attached hereto as Exhibit A).

In addition, AAEC's members include providers of goods and services to power plants, in particular coal-fired power plants, including those affected by the Phase II RHR SIP. These providers of goods and services would be harmed financially if, instead of installing additional controls, any of these plants were to curtail or modify operations or close pursuant to the Phase II RHR SIP.

AAEC generally supports the proposed Phase II RHR SIP, which is intended to address certain elements of the State of Arkansas's Regional Haze Rule SIP for the first Regional Haze Rule planning period that were disapproved by EPA in 2012. The first Regional Haze Rule planning period ends on December 31, 2018; consequently, the Phase II SIP should focus on and be limited to one-time BART determinations and Reasonable Progress and Long Term Strategy requirements for the planning period that ends Dec. 31, 2018. Controls, strategies, limits, determinations and other requirements that take effect after that date should not be adopted or made finally enforceable as part of the Phase II RHR SIP revision.¹

¹ To the extent that the Phase II RHR SIP relies on or utilizes elements of the Final Rule, Protection of Visibility: Amendment to Requirements of State Plans, 82 F.R. 3078 (Jan. 10, 2017) ("2017 RHR Amendments") or any guidance issued with respect to that final rule, ADEQ should consider whether those parts of the plan should be modified or deleted to avoid reliance on that final rule and associated guidance. The Phase II RHR SIP is intended to address certain elements of the State's RHR that were disapproved by EPA in 2012. EPA's disapproval of the SIP in 2012 was based on regulations and guidance that were in effect at that time; consequently, in addressing the disapproved elements of the SIP it is appropriate to use the same regulations as EPA used for its disapproval. In addition, it should be noted that the 2017 RHR Amendments are the subject of litigation in the D.C. Circuit Court of Appeals, and that EPA has recently published notice of its intent to reconsider that rule. See, <https://www.epa.gov/visibility/epas-decision-revisit-aspects-2017-regional-haze-rule-revisions> (Jan. 18, 2018).

BART DETERMINATION FOR ENTERGY'S WHITE BLUFF UNITS

AAEC supports ADEQ's determination that improved use of low sulfur coal ("LSC") constitutes Best Available Retrofit Technology for the White Bluff units. There is less than one year remaining in the first planning period, and improved use of LSC is an effective control that can actually be implemented during the first planning period. ADEQ's BART analysis and BART determination should not be premised on any plan for early retirement or cessation of use of coal at White Bluff during the next or any future planning period. Such a requirement is outside the scope of this SIP since it would not take effect during this planning period. In addition, BART does not require the premature retirement of White Bluff or fuel switching. Furthermore, early closure of White Bluff or cessation of use of coal, as contemplated in Entergy's proposed five-factor analysis as a practical matter requires Entergy and the other White Bluff co-owners to obtain the the approval of other regulatory authorities. See, Declaration of Kurt Castleberry, January 11, 2018, ¶¶ 17-26 (copy attached hereto as Exhibit A); Declaration of Jonathon F. Long, January 11, 2018, ¶¶ 9-13, (copy attached hereto as Exhibit B). Consequently, any such requirement is not practically or finally enforceable at this time, and should not be included in the Phase II RHR SIP.

ADEQ's determination of LSC as BART is supported even without taking into account Entergy's proposed early retirement date or cessation of use of coal

date. In addition, ADEQ's selection of a later date than the date contained in Entergy's five factor analysis also is supported.

The cost of controls, and "cost-effectiveness" in terms of the cost per ton of pollutants removed, is only one of five factors that must be considered in arriving at a BART determination. While a high cost/ton figure could be used to eliminate certain technologies from further consideration, over-reliance on cost-effectiveness calculations based on an arbitrary remaining useful life does not properly take into account or give proper effect to other BART factors. For example, even where a technology is determined to be cost-effective, a decision to select another cost-effective technology can be justified based on other factors, for example minimal visibility improvements. See 77 Fed.Reg. 23988, 24031 (April 29, 2012) (determining that BART was use of LSC instead of dry sorbent injection, even though DSI was determined to be cost-effective). As EPA recently stated in approving the State of Louisiana's determination of low sulfur coal as BART:

Each BART determination is dependent on the specific situation and requires consideration of a number of factors including, the characteristics of the fuel burned at the source, the existing controls, the control efficiency of available control technologies, the remaining useful life, the costs and incremental costs of controls and the anticipated visibility benefit of each potential control. The Regional Haze Rule and BART Guidelines do not require the state to select as BART a more effective technology merely because it has visibility benefits or cost effectiveness that fall within the range of previous cases, nor do they prohibit the state from choosing as BART a less

effective technology measure that falls outside the range of previous cases. The state must consider all 5 statutory factors.

(82 Fed.Reg. 60520, 60535, Dec. 21, 2017).

Entergy's most recent visibility analysis in its August 18, 2017, five factor analysis for White Bluff continued to present visibility impacts using the CALPUFF model. This modeling purports to demonstrate that the difference in visibility improvement between LSC and the most stringent control technology is less than 0.5dv. As explained in Nucor and NYS's April 8, 2015 comments on EPA's proposed Regional Haze Rule Federal Implementation Plan for Arkansas, use of CALPUFF modeling at the distances involved for the Arkansas Class I areas results in overestimation of visibility impacts by at least five (5) times if not more. See, Nucor and NYS Comments on EPA's proposed Regional Haze Rule Federal Implementation Plan, EPA Docket No. EPA-R06-OAR-2015-189, at pages 40-50 and the report of Dr. Richard McNider (copies attached as Exhibits C and C-2, respectively). Thus, in reality both the overall visibility improvement at Arkansas Class I areas from the use of control technologies, as well the difference in visibility improvement between use of LSC and use of other more expensive

technologies is negligible.² Furthermore, as Entergy noted in its five factor analysis,

Trinity and EAI assert that CALPUFF is not the most appropriate model for estimating visibility impacts. Due to its numerous inherent limitations (e.g., limited chemistry mechanism, distance limitations, blanket background ammonia values, etc.), CALPUFF does not yield reliable results. Furthermore, CALPUFF is no longer an EPA-preferred model, which further indicates CALPUFF's unreliability. More advanced models like the Comprehensive Air Quality Model with Extensions (CAMx)—if processed appropriately—can yield more reliable characterizations of visibility impairment.

See, Entergy's August 17, 2017 updated five factor analysis for White Bluff, footnote 7. Furthermore, as discussed at page 46 of the proposed Phase II RHR SIP, use of the more advanced CAMx model on the Entergy Independence plant produced modeled visibility impacts **ten (10) times less** than the modeling impacts reported using the CALPUFF model. Presumably, use of CAMx modeling for

² BART requires consideration of the "degree of visibility improvement which may reasonably be anticipated to result from the use of such technology." 42 U.S.C. §7491(g)(2). Based on (a) the acknowledged deficiencies in the CALPUFF model under the circumstances present and the parameters used for modeling the White Bluff units, (b) the analyses submitted in support of Nucor and NYS's comments on the EPA Regional Haze Rule FIP, (c) the small amount of light extinction from SO₂ at Arkansas Class I areas attributable to all Arkansas point sources, and (d) the demonstrated differential between the results of CALPUFF modeling and CAMx modeling for Entergy's sister Independence facility, the visibility improvement that may reasonably be anticipated from use of any of the evaluated technologies is an order of magnitude lower (or more) than presented in Entergy's five factor analysis (Tables 3-2, 4-6, 4-7, B-8, B-9), and is far below any perceptible visibility improvement (1.0 dv), and likely well below the 0.5 dv threshold for determining that a unit is subject to BART.

White Bluff would show similar negligible visibility improvements, i.e., ten times less than those presented in Entergy's five factor analysis and consistent with Dr. McNider's assessment and opinion. As a result, use of LSC indefinitely instead of installing some other technology or premature retirement of White Bluff is justified as BART.

In addition, use of a premature retirement date or cessation date for use of coal to determine BART for White Bluff is inappropriate in these circumstances under applicable regulations and guidance.³ EPA guidance from the 1980 RAVI BART Guidelines states:

For example, BART could alter the economics of the plant to the point where the decision would be made to cancel expansion of the facility, to reduce the scale of operation, or to change the production mix. The local employment effects, including number of jobs, dollars paid in salaries, and changes in employee skill levels required should be evaluated. The guideline does not imply that the BART decision should force a plant to the brink of shutdown. The BART decision must be based on sound judgment, balancing environmental benefits with energy, economic, and other impacts. [emphasis supplied]

Guidelines for Determining Best Available Retrofit Technology for Coal-Fired Power Plants and Other Existing Stationary Facilities, EPA-450/3-80-009b (1980), p. 20. Appendix Y to 40 C.F.R. Part 51 states "it is not our intent to direct States

³ It should be noted that the State of Louisiana recently determined that use of low sulfur coal was BART for Entergy's coal-fired Nelson plant, and EPA has approved that determination. 82 Fed.Reg. 60520, Dec. 21, 2017. That BART determination was not based on any retirement date or cessation of coal use date.

to switch fuel forms, e.g., from coal to gas. . . . We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis.” (Appendix Y, IV.D.3, 5). Appendix Y also warns that even if control technology is cost effective “there may be cases where the installation of controls would affect the viability of continued plant operations.” Appendix Y, IV.E.3. As explained in the Declaration of Kurt Castleberry, the premature deactivation of White Bluff or Independence, will result in severe local economic impacts including loss of jobs and erosion of the local tax base. Declaration of Kurt Castleberry, January 11, 2018, ¶¶ 27-30 (copy attached hereto as Exhibit A). To the extent that the Phase II RHR SIP BART determination for White Bluff is based on a premature plant retirement date that has not been approved, but would otherwise result in significant costs that would affect the viability of continued operation of White Bluff before the end of its actual remaining useful life, the BART determination is contrary to the intent of the Clean Air Act and the BART guidelines.⁴

⁴ On the other hand, the cost analysis in Entergy’s updated five-factor analysis fails to take into account the historical and existing use of low-sulfur coal at White Bluff. As explained in the attached September 14, 2017 white paper –

In summary any early retirement date for White Bluff or an early date for cessation of coal use would require other regulatory approvals, and thus cannot be the basis for an enforceable condition in the Phase II RHR SIP. Nevertheless, because of the excessive costs of DSI or FGD when the additional costs of continued use of LSC are included, and because of the miniscule and imperceptible visibility impacts to be expected from the use of DSI or FGD, either in absolute terms or in comparison with visibility impacts from use of LSC, the indefinite use of LSC, or a longer use of LSC than proposed by Entergy, is justified as BART. Because Entergy's proposed retirement date for White Bluff or the cessation of use of coal at White Bluff is contingent, the BART determination for SO₂ at White Bluff should explicitly recognize that contingency, and rely instead on the indefinite use of LSC as BART.

“Consideration of Low-Sulfur Coal in a BART Five-Factor Analysis for the White Bluff Power Plant” which is attached hereto as Exhibit D and incorporated herein by reference - the proposed use of dry flue gas desulfurization as BART is premised on the continued use of low sulfur coal as a fuel source; consequently, the historic and ongoing costs of acquiring, transporting and using low sulfur coal (instead of a less expensive, higher heat content coal) must be added to the costs of for additional controls such as FGD or DSI, which would result in an even higher cost/ton number for those control technologies.

REASONABLE PROGRESS ANALYSIS

AAEC also supports ADEQ's analysis of the visibility glidepath and the determination that Arkansas has already achieved its Reasonable Progress goals for the first regional haze rule planning period. AAEC also agrees that as a result of this determination that no additional controls beyond BART are necessary to achieve the Arkansas Reasonable Progress goals for this planning period.⁵ In this regard, AAEC notes ADEQ's determination that only a very small portion of light extinction from SO₄ and NO₃ at the Arkansas Class I areas comes from point sources located within the State of Arkansas, and that most of the light extinction comes from sources located outside the State.⁶

With regard to ADEQ's reasonable progress analysis for Entergy's Independence plant, AAEC disagrees that additional emission limits for SO₂ are necessary in order to achieve the State's reasonable progress goals for this planning period. As indicated, the reasonable progress goals have already been met, there are only a few months left in this planning period, there is no suggestion that the Independence plant would change its use of LSC, and thus no additional

⁵ See, Nucor and NYS Comments on EPA's proposed Regional Haze Rule Federal Implementation Plan, EPA Docket No. EPA-R06-OAR-2015-189, at pages 16-19, which are attached hereto as Exhibit C, that controls under the reasonable progress analysis must be "necessary."

⁶ See, Figures 2 – 9 of the Phase II RHR SIP.

controls or emission limits are necessary for purposes of the regional haze rule.⁷

Furthermore, to the extent such controls might be necessary to continue visibility progress in the next planning period, then such controls should be considered in the SIP for that planning period – not this one.⁸ In addition, ADEQ’s reasonable progress analysis for Independence is improper because it constitutes an individual, single-source reasonable progress analysis. As explained in Nucor and NYS’s comments on EPA’s Regional Haze Rule Federal Implementation Plan for Arkansas:

Reasonable progress provisions are intended to address contributions from a wide range of sources that can be best addressed on a source-category basis. They are fundamentally different from other provisions such as those for BART and reasonably attributable visibility impairment (“RAVI”), which are specifically designed to address individual sources.

Nucor and NYS Comments on EPA’s proposed Regional Haze Rule Federal Implementation Plan, EPA Docket No. EPA-R06-OAR-2015-189, attached hereto as Exhibit C, at page 19.

⁷ AAEC notes that visibility is projected to improve in the State of Arkansas and stay well below the Uniform Rate of Progress long into the next regional haze rule planning period.

⁸ AAEC notes that ADEQ did not propose additional reasonable progress controls for Independence in the State’s Five Year Regional Haze Rule Progress Report to EPA.

In summary, because the State of Arkansas has met its reasonable progress goals for the first planning period, no additional controls, by way of emission limitations or otherwise, are necessary to achieve reasonable progress. As a result, no additional emission limitations are needed for Independence

LONG TERM STRATEGY

The AAEC also supports ADEQ's proposed Long Term Strategy. AAEC notes that there is less than a year left in the first regional haze rule planning period and that the State's reasonable progress goals have already been met. AAEC also notes that the proposed Long Term Strategy recognizes planned retirements of large power plants in Texas during 2018 that affect Arkansas Class I areas. Any future retirements of stationary sources that may occur after the end of the first planning period should be addressed in long term strategies for future planning periods.

INTERSTATE VISIBILITY TRANSPORT

AAEC also supports ADEQ's determination that no additional controls, provisions or measures are necessary in order to satisfy the so-called interstate visibility transport provisions of 42 USC §7410(a)(2)(D)(i)(II). ADEQ has not identified any measure included in any other state's implementation plan to protect

visibility that will be interfered with by emissions from any source or emissions activity within the State.

PROVISIONS OF THE ADMINISTRATIVE ORDERS

Several provisions of the proposed Administrative Order (“AO”) for Entergy should be deleted or modified consistent with the comments above. The SIP and the AO should explicitly recognize that the early closure or cessation of use of coal at White Bluff is not required in connection with the use of LSC as BART. The SIP and the AO also should explicitly recognize that no additional controls or emission limitations are necessary at Independence in order to achieve reasonable progress during the first regional haze rule planning period.

This clarification is necessary in light of ambiguous language in the AO wherein ADEQ references Entergy’s prior proposal to close or cease using coal at White Bluff by a date certain, as well as proposed emission limits for Independence that are not necessary in this regional haze rule planning period. AAEC notes that in ADEQ’s December 18, 2017 Notice of Data Availability (“NODA”) ADEQ acknowledged that “Entergy may have additional obligations regarding reliability and cost recovery with respect to the two facilities referenced in this NODA that are outside the scope of ADEQ’s authority and outside the scope of the Proposed SIP.” ADEQ December 18, 2017 NODA at page 2.

Clarification is needed to emphasize that the reference to future operation of White Bluff is informational and is not intended to create mandatory, federally enforceable requirements of the SIP that, for the reasons noted above, would be contrary to law. Specifically, paragraph 10 of the Findings of Fact should be modified to provide that no additional controls or emission limits are needed for the Independence facility in order to achieve reasonable progress during this planning period. Paragraph 3 of the Order should be modified to recognize that any early retirement or cessation of use of coal at White Bluff is contingent on other regulatory approvals for Entergy and the co-owners of White Bluff, and thus cannot be the basis of an enforceable limitation under the AO, and that BART constitutes use of LSC. Paragraph 5 of the Order should be removed or modified.

We applaud ADEQ's use of Paragraph 10 of the Order to allow modification of the Administrative Order during future regional haze rule planning periods to account for ever-changing circumstances that could materially impact future Reasonable Progress assessments or Long Term Strategies. For example the AO could be modified to include emission limitations on Independence based on the use of LSC, or to include an enforceable early retirement date or date for cessation of use of coal at White Bluff if all necessary approvals have been obtained from the Arkansas Public Service Commission and other regulatory authorities. By the same token, the AO could be modified in the future to factor-in new control

technologies or visibility measurement techniques or changes in governing regulations. These types of changed circumstances are the reason that current EPA regulations contemplate adjustments to reasonable progress determinations and long term strategies, including prior determinations and proposals in future planning periods.

In addition, the AO also should include a provision for public notice and comment on any future modifications of the AO. This will ensure that stakeholders will be able to fully scrutinize such modifications and provide the Department valuable input.

FEBRUARY 2, 2018

REVISIONS TO THE ARKANSAS STATE IMPLEMENTATION PLAN
REGIONAL HAZE SIP REVISION FOR 2008-2018 PLANNING PERIOD

EXHIBIT A

Declaration of Kurtis W. Castleberry, Jan. 11, 2018

Declaration of Kurtis W. Castleberry
Director, Resource Planning and Market Operations, Entergy Arkansas, Inc.

**DECLARATION OF KURTIS W. CASTLEBERRY
IN SUPPORT OF MOTION TO STAY FINAL RULE OF THE
U.S. ENVIRONMENTAL PROTECTION AGENCY
BY ENTERGY ARKANSAS, INC., ENTERGY MISSISSIPPI, INC.,
ENTERGY POWER, LLC, AND ENERGY AND ENVIRONMENTAL
ALLIANCE OF ARKANSAS**

I, Kurtis W. Castleberry, hereby state as follows:

1. I am the Director of Resource Planning and Market Operations for Entergy Arkansas, Inc. ("EAI"). I am making this declaration in support of the motion by EAI, Entergy Mississippi, Inc. ("EMI"), and Entergy Power, LLC ("EPI") (collectively, the "Entergy Companies"), and Energy and Environmental Alliance of Arkansas ("EEAA") to stay the final regional haze plan for Arkansas issued by the U.S. Environmental Protection Agency ("EPA"), titled "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan" ("Final Rule").
2. I am over 18 years of age, of sound mind, and in all respects competent to make this declaration.
3. I received a Bachelor of Science Degree in General Engineering from Arkansas Tech University in 1982. I received a Master's Degree in International Business from Webster University in 1995.
4. I have been employed by EAI and its affiliates for 35 years. EAI is an electric utility engaged in the generation, purchase, transmission, distribution and sale of electricity primarily in Arkansas. EAI provides electrical utility service to approximately 712,000 residential and commercial electric customers. EAI

owns portions of the two coal-fired electric generating units at the White Bluff Electric Power Plant ("White Bluff") and one of the two coal-fired electric generating units at the Independence Steam Electric Station ("Independence"). EAI operates both White Bluff and Independence pursuant to an agreement with the other co-owners. EAI is a regulated public utility subject to the rate and general operating jurisdiction of the Arkansas Public Service Commission ("APSC") and the Federal Energy Regulatory Commission ("FERC"). All of the stock of EAI is owned by Entergy Corporation.

5. EMI is an electric utility engaged primarily in the generation, purchase, transmission, distribution and sale of electricity in Mississippi and is a co-owner of the coal-fired electric generating units at Independence. EMI provides electrical utility service to approximately 447,000 residential and commercial electric customers. EMI is a regulated public utility subject to the rate and general operating jurisdiction of the Mississippi Public Service Commission ("MPSC") and FERC. All of the stock of EMI is owned by Entergy Corporation.
6. EPI is an electric utility company that sells electric energy at wholesale and is a co-owner of the coal-fired electric generating units at Independence. Its principal business office is located in The Woodlands, Texas. EPI is an indirect wholly owned subsidiary of Entergy Corporation.
7. In my current position, I lead EAI's Resource Planning and Market Operations team, which is responsible for the management and administration of EAI's resource planning and operations activities as a member of the Midcontinent Independent System Operator, Inc. ("MISO") Regional Transmission Organization. My team's duties include conducting resource planning activities for EAI, such as developing and implementing EAI's integrated resource plan

for meeting the load and energy requirements of EAI's customers. I also serve as the Chairman of EAI's Resource Planning and Operations Committee, which reviews and provides advisory input and recommendations on a number of planning and operational issues for EAI to the EAI President and Chief Executive Officer. My group also manages the relationship between EAI and the co-owners of Independence and White Bluff, which include, variously, EMI, EPI, Arkansas Electric Cooperative Corporation ("AECC"), East Texas Electric Cooperative ("ETEC"), and several Arkansas municipalities: the City of Conway, the City of West Memphis, the City of Jonesboro, and the City of Osceola.

8. Independence is located in Newark, Arkansas, and has two coal-fired electric generating units, the 836-megawatt ("MW") Unit 1 and the 842 MW Unit 2. Independence is owned by several co-owners, including EAI, EMI, and EPI, as well as several not-for-profit entities, such as AECC, ETEC, and the City of Osceola, and several EEAA members, including the City of Conway, the City of West Memphis, and the City Water and Light Plant of the City of Jonesboro. EAI operates both units pursuant to an Operating Agreement among the co-owners.
9. White Bluff is located in Redfield, Arkansas, and has two coal-fired electric generating units, the 815-MW Unit 1 and the 820-MW Unit 2. White Bluff is owned by several co-owners: EAI and several not-for-profit entities, such as AECC, and several members of EEAA, including the City of Conway, the City of West Memphis, and the City Water and Light Plant of the City of Jonesboro. EAI operates both units pursuant to an Operating Agreement among the co-owners.

I. **Requirements for Nitrogen Oxides Emissions Reductions at White Bluff and Independence**

10. The Final Rule requires each coal-fired unit at White Bluff and Independence to meet a nitrogen oxides (“NO_x”) emission limit of 0.15 pounds per million British thermal units (“lb/MMBtu”) on a rolling 30-boiler operating day basis at loads of 50-100 percent of maximum heat input rating (the “full load limit”), and a rolling 3-hour average limit of 671 pounds per hour (“lb/hr”) at loads of less than 50 percent of maximum heat input rating (the “low load limit”). These emission limits are based on the installation of low-NO_x burners and separated overfire air technology (“LNB/SOFA”) on each unit. These limits must be met beginning April 27, 2018.
11. EAI has completed installation of LNB/SOFA at three of the coal-fired units and is scheduled to begin installation at the fourth unit in mid-January. *See* Declaration of Bryan Sikes, Entergy Services, Inc., at ¶ 10.
12. The NO_x controls are currently not performing as anticipated and the three units where the controls have been installed are unable to reliably meet the Final Rule’s NO_x limits. *See id.* at ¶¶ 11, 15, 16. There will not even be time before the April 27, 2018 compliance deadline to properly tune the NO_x controls on the fourth unit to determine whether the controls will meet the NO_x limits. *Id.* at ¶ 11.
13. If a stay is not granted and EAI is unable to achieve compliance with the NO_x emission limits across all operating conditions at the units by April 27, 2018, EAI would need to explore temporary operational restrictions for the units that would allow the units to meet the NO_x emission limits, *see id.* at ¶ 17, which

would result in irreparable harm to EAI and its co-owners. EAI would have to inform its regional transmission operator, MISO, of the operating restrictions, which could impact MISO's dispatch of the units. Any operational restrictions that limited the units' dispatch would have negative financial impacts on EAI, its customers, and its co-owners. The financial impacts could not be calculated without a firm understanding of which operational restrictions would be effective in allowing the units to meet the NO_x emission limits, but the impacts likely would be multiple millions of dollars.

II. Requirements for Sulfur Dioxide Emissions Reductions at White Bluff and Independence and Compliance Planning Process

14. The Final Rule requires each coal-fired unit at White Bluff and Independence to meet a 50 boiler operating day rolling average sulfur dioxide ("SO₂") emission limit of 0.06 pounds per million British thermal units ("lb/MMBtu") by October 27, 2021. This emission limit is based on the installation of a dry scrubber (flue gas desulfurization ("FGD") technology) on each unit.
15. The Final Rule, if not stayed, exposes the plants' co-owners (including the Entergy Companies and their shareholders), and their customers and communities to immediate and irreparable harm. In light of the fact that the state has proposed a state implementation plan ("SIP") to replace the Final Rule, which would not require EAI to install FGD on any the units, EAI is not currently expending resources to design, procure, or install FGD at White Bluff and Independence. As a result, if a stay of the SO₂ limits is not granted and the Final Rule is not superseded, EAI would have to deactivate the White Bluff and Independence units by October 27, 2021, and obtain replacement power.
16. To plan for the possibility that the Final Rule will not be successfully superseded, either because EPA does not approve it or it is overturned through

litigation, the process to deactivate the units and obtain replacement capacity is complex and must begin in 2018. EAI and its co-owners would have to replace over 3,300 MW if the units were deactivated, which would require EAI and its co-owners (other than EPI) to undertake a resource procurement process. If constructing additional generation, likely a combined cycle gas turbine (“CCGT”), were determined to be the best option for EAI, this could not be done by October 27, 2021. *See* Declaration of Jonathan Long, Entergy Services, Inc., at ¶ 11.

III. Deactivation and Replacement Capacity Compliance Path

1. Deactivation Process

17. A decision to retire a unit can have significant implications for the remainder of the grid, some of which may require upgrades to the transmission system to ensure that the grid can be operated reliably after the generating unit is retired. Accordingly, owners/operators of a generating unit typically request that MISO perform an “Attachment Y-2 study,” which would determine, on a non-binding basis, whether the retirement of the generating unit would affect transmission system reliability, or whether the unit would need to continue to operate until transmission upgrades or other system changes to maintain reliability can be completed. In EAI’s experience, an Attachment Y-2 study takes approximately three to four months for a standard request. However, this situation is not standard, and assessing the retirement of four units totaling over 3,300 MW of capacity may take much longer. EAI would incorporate the Attachment Y-2 results into its internal economic analysis. Depending on the time needed to perform the economic analysis, coordinate with co-owners, and obtain the results of MISO’s Attachment Y-2 study, this decision-making process would take between six and nine months.

18. In addition to the Attachment Y-2 study, if a decision to deactivate is made, EAI would need to provide at least six months' notice of its intent to retire the unit to MISO. Upon receipt of the notice, MISO would conduct an "Attachment Y study" to determine if the generator can retire in a manner consistent with reliability. MISO endeavors to complete this determination within 75 days, but in EAI's experience, it has taken between four and nine months.
19. To allow sufficient time for EAI and MISO to complete these steps, the planning must begin by the second or third quarter of 2018. Although the exact cost of the deactivation planning steps over the next 12-24 months has not yet been projected, based on past experience they will cost several million dollars.

2. Replacement Capacity

20. If the units must be deactivated, the co-owners would need to replace the over 3,300 MW in electricity generation capacity from White Bluff and Independence that are necessary to meet the needs of their respective customers and to satisfy the co-owners' respective obligations to MISO. The over 3,300 MW from these two plants is enough to power approximately 500,000 homes at peak hours.¹ It represents approximately 23 percent of the total net generation in the state of Arkansas, according to 2015 data from the U.S. Energy Information Administration. Additionally, I understand that the combined 251 MW owned by the City Water and Light Plant of the City of Jonesboro represents approximately 80% of that co-owner's customers' electric

¹ This calculation assumes 10 percent line losses and 6 kW per home at the time of peak.

capacity demand and more than 65% of their energy usage. *See* Declaration of Jake Rice, III, Jonesboro City Water and Light, at ¶ 11.

21. To evaluate the best options to replace the capacity from these two power plants, EAI and its co-owners (other than EPI) each would undertake a resource planning process. Where constructing additional generation is determined to be the best option, the specific co-owner would need to begin designing, constructing, and making operational a new generating unit to provide the replacement generation, as well as seeking to obtain any required approvals, including preconstruction permitting and regulatory rate adjustment approvals. Constructing replacement capacity is a lengthy process, and approval from the APSC would be required in connection with the construction and/or purchase of a new generating unit. *See* Declaration of Jonathan E. Long at ¶¶ 11.
22. Replacement capacity and associated energy cannot be installed by the October 27, 2021, compliance deadline in the Final Rule. *Id.* Therefore, until the replacement capacity and associated energy is available, the co-owners would have to purchase replacement capacity, either through a specific agreement or through MISO's annual capacity auction, and purchase replacement energy (as opposed to replacement capacity) through the operation of MISO's day-ahead and real-time markets. The co-owners' respective customers would be exposed to the market price, and its inherent variability, for this power.
23. Being dependent on the MISO annual capacity auction and its day-ahead and real-time energy markets for such a large amount of capacity and energy would expose customers to an unacceptable level of price risk, which would include being required to pay MISO's Cost of New Entry ("CONE"). If MISO is unable to clear sufficient capacity to meet the peak load plus reserve margin

requirement for a Local Resource Zone (“LRZ”) through the annual MISO Planning Resource Auction (“PRA”), then the LRZ would clear at the CONE price. EAI would not hold an amount of capacity sufficient to meet its peak load plus reserve margin in the annual PRA. If the Arkansas LRZ cleared at the CONE price, absent EAI procuring replacement capacity under a specific agreement, its customers would be charged CONE for the capacity deficit and they also would be subjected to the volatility of prices in the day-ahead and real-time energy markets. Accordingly, if a stay of the Final Rule is not granted, EAI likely would choose to purchase replacement capacity through a specific agreement. EAI would need to begin the process in the second or third quarter of 2018 to ensure that a contract is in place for replacement capacity before October 27, 2021. However, there is no guarantee that approximately 3,300 MW of capacity would be available, regardless of the price paid.

24. To begin the process for obtaining replacement capacity, EAI would first need to develop a market solicitation request for proposals (“RFP”) for capacity and energy to replace White Bluff and Independence. This is a complex undertaking that would take approximately six months to prepare. If the RFP were completed by the first quarter of 2019, bids would then be solicited in the second to third quarter 2019. EAI would then evaluate the bids and likely hire an independent monitor to ensure fairness in the evaluation, with the goal of obtaining commercial agreements by mid-2020.
25. Regulatory approval of the commercial agreements also would be required to ensure that the regulator found the agreements to be in the public interest. This process likely would take a year or longer to complete and would entail preparation of a petition and supporting testimony for an APSC public interest proceeding, the completion of discovery, an APSC-determined procedural

schedule with multiple rounds of testimony from the APSC General Staff, the Arkansas Attorney General's office, and potentially other intervenors, a public hearing, and the issuance of a final order. The state regulatory process would take even longer if there were any challenges to the APSC's final order, which could include an administrative petition for rehearing and subsequent appeal.

26. Although the exact cost of the replacement capacity planning steps over the next 12-24 months has not yet been projected, based on past experience they will cost several million dollars.

3. Impact of Deactivation

27. Ceasing operations at White Bluff in 2021 would harm White Bluff employees and local businesses. According to research by AFCC, the White Bluff plant is estimated to support 1,237 direct and indirect jobs.² There are 115 full-time employees at White Bluff. White Bluff also employs approximately 300 contractors for at least six weeks in the spring and fall each year for planned outage support. Additionally, there are about 20 contractors that work full time in security, coal dust management, janitorial, lawn maintenance, ash management and scaffolding support.
28. Ceasing operations at Independence in 2021 would harm Independence employees and local businesses. There are 115 full-time employees at Independence. Independence also employs hundreds of contractors for

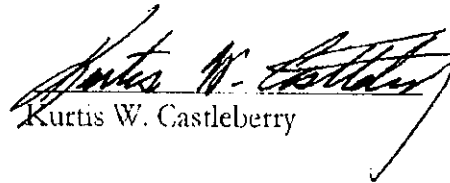

² Willie Lee Brooks, Jr., Senior Analyst, Economic & Financial Risk, *What is the Economic Impact of the White Bluff Electric Power Plant?*, at 2, Arkansas Electric Cooperative Corporation (May 30, 2014), available at <http://www.arkleg.state.ar.us/assembly/2015/Meeting%20Attachments/890/112666/HANDOUT%20%20-%20HIGHLIGHT%20%20Economic%20Impact%20of%20White%20Bluff%20Electric%20Pwr%20Plant.pdf>. No such study has been conducted for Independence.

planned outage support, and contractors who provide janitorial services, maintenance support, ash disposal services, and work on insulation and scaffolding.

29. If White Bluff and Independence were to cease operations in 2021, these employees would have to be reassigned or laid off, and the contractors would be out of work.
30. The co-owners of White Bluff also pay approximately \$2 million annually in county property taxes related to the operation of the plant. Similarly, the co-owners of Independence pay approximately \$2 million annually in county property taxes related to the operation of the plant. The total estimated value of White Bluff to its local economy is \$173 million.³ Deactivation of White Bluff and Independence would significantly reduce this local revenue.

I declare under penalty of perjury that the foregoing statements are true and correct based on my personal knowledge and information gathered and provided to me by the Entergy Companies' personnel and consultants.

Executed this 11th day of January, 2018.

Kurtis W. Castleberry

COMMENTS OF THE ARKANSAS AFFORDABLE ENERGY COALITION
FEBRUARY 2, 2018

REVISIONS TO THE ARKANSAS STATE IMPLEMENTATION PLAN
REGIONAL HAZE SIP REVISION FOR 2008-2018 PLANNING PERIOD

EXHIBIT B

Declaration of Jonathan E. Long, Jan. 11, 2018

Declaration of Jonathan E. Long
Vice President, Capital Projects, Entergy Services, Inc.

EXHIBIT B

**DECLARATION OF JONATHAN E. LONG
IN SUPPORT OF MOTION TO STAY FINAL RULE OF THE
U.S. ENVIRONMENTAL PROTECTION AGENCY
BY ENTERGY ARKANSAS, INC., ENTERGY MISSISSIPPI, INC.,
ENTERGY POWER, LLC, AND ENERGY AND ENVIRONMENTAL
ALLIANCE OF ARKANSAS**

I, Jonathan E. Long, hereby state as follows:

1. I am employed by Entergy Services, Inc. as the Vice President, Capital Projects. I am making this declaration in support of the motion by Entergy Arkansas, Inc. ("EAI"), Entergy Mississippi, Inc. ("EMI"), and Entergy Power, LLC ("EPP") (collectively, the "Entergy Companies"), and Energy and Environmental Alliance of Arkansas ("EEAA") to stay the final regional haze plan for Arkansas issued by the U.S. Environmental Protection Agency ("EPA"), titled "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan" ("Final Rule").
2. I am over 18 years of age, of sound mind, and in all respects competent to make this declaration.
3. I received a Bachelor of Science degree in Electrical Engineering from Mississippi State University in 1982 and a Master of Business Administration from Pepperdine University in 1991. I have been employed by Entergy Services, Inc. since 2006. From 1995 to 2006, I was employed by Entergy Enterprises, Inc., an affiliate of Entergy Services, Inc. In my current position, I oversee the development and execution of major capital projects for the corporation, primarily for Entergy's fleet of fossil fuel power generation plants and Entergy's transmission system. I manage a team of project managers, project engineers and discipline engineers that develops the scope, predicted performance, cost

EXHIBIT B

and schedule for these large capital projects and oversees the projects from conception through execution.

4. Entergy Services, Inc. provides administrative, accounting, legal, engineering, and other services primarily to the Entergy utility operating companies, including EAI and EMI. Entergy Services, Inc. is wholly owned by Entergy Corporation.
5. The Independence Steam Electric Station (“Independence”) is located in Newark, Arkansas, and has two coal-fired electric generating units, the 836-megawatt (“MW”) Unit 1 and the 842-MW Unit 2. Independence is owned by several co-owners, including EAI, EMI, and EPI, as well as several not-for-profit entities, such as Arkansas Electric Cooperative Corporation (“AECC”), East Texas Electric Cooperative (“ETEC”), and the City of Osceola, and several members of EEAA, including the City of Conway, the City Water and Light Plant of the City of Jonesboro, and the City of West Memphis.
6. The White Bluff Electric Power Plant (“White Bluff”) is located in Redfield, Arkansas, and has two coal-fired electric generating units, the 815-MW Unit 1 and the 820-MW Unit 2. White Bluff is owned by several co-owners: EAI and several not-for-profit entities, such as AECC and ETEC, and several members of EEAA, including the City of Conway, the City Water and Light Plant of the City of Jonesboro, and the City of West Memphis.
7. The Final Rule requires each coal-fired unit at White Bluff and Independence to meet a 30-boiler operating day rolling average sulfur dioxide (“SO₂”) emission limit of 0.06 lb/MMBtu beginning October 27, 2021. This emission limit is based on the installation of a dry scrubber (flue gas desulfurization (“FGD”) technology) on each unit.

EXHIBIT B

8. To meet the Final Rule's SO₂ emission limits at White Bluff and Independence, EAI, as operator of all four units, must either (1) deactivate the White Bluff and Independence units by the FIP's ultimate compliance deadline of October 27, 2021, or (2) install dry flue gas desulfurization ("dry FGD") by that date. I understand that Entergy is not currently expending resources to design, procure, or install FGD at White Bluff and Independence in light of a proposed state regulation that could supersede the Final Rule. *See* Declaration of Kurtis Castleberry, Entergy Services, Inc., at ¶ 15. It is not clear whether that state regulation will be approved or, if approved, litigated and thus Entergy must act prudently and make necessary preparations for all outcomes, including compliance with the Final Rule, which remains in effect. Accordingly, if the Final Rule is not stayed, EAI must start planning to expedite development of new generation assets to replace the capacity provided by White Bluff and Independence.
9. If the units are deactivated, EAI and the co-owners would need to replace the over 3,300 MW in electricity generation capacity from White Bluff and Independence that are needed to meet the needs of their respective customers and to satisfy the co-owners' respective obligations to MISO. *See* Declaration of Jake Rice, III, Jonesboro City Water & Light, at ¶¶ 11, 16.
10. To evaluate the best options to replace the capacity from these two power plants, EAI and its co-owners (other than EPI) each would undertake a resource planning process. Where constructing additional generation is determined to be the best option, the specific co-owner would need to begin designing, obtaining preconstruction permits for, constructing, and making operational one or more new generating units to provide the replacement generation, as well as seeking to obtain any required approvals, such as regulatory approvals. Given today's

EXHIBIT B

circumstances, any new unit constructed likely would be a combined cycle gas turbine (“CCGT”). The process for constructing even a single new unit is complex.

11. Construction of any new CCGT unit likely would require construction of a new gas pipeline and, depending on where it is built, acquisition of rights-of-way. Transmission infrastructure would need to be built to connect any new unit with the grid. In addition to projects that would need to be completed to ensure reliability after the deactivation of White Bluff and Independence, as identified in ¶ 12 below, the new unit would need to be evaluated by MISO to determine the upgrades that will be necessary for the unit to deliver its output to the load that it will serve. It would take five years, at a minimum, to prepare and submit the necessary environmental permit applications, prepare requests for proposals for construction, select a vendor, and obtain the necessary permits and approvals, including approval from the Arkansas Public Service Commission, for the transmission interconnection work. As a result, this work cannot be completed by October 27, 2021. It would take until sometime in 2023, at the earliest, to complete this transmission infrastructure development.
12. Separate and apart from any replacement generation project, EAI and EMI also would need to begin planning transmission projects to maintain reliability during the period between the time White Bluff and Independence ceased operating and the replacement generation came on line (the “bridge period”). For example, without a stay of the Final Rule, EAI would have to begin identifying projects by second to third quarter of 2018 and likely would spend hundreds of thousands of dollars in scoping the projects. More significant sums would be expended next year for major project work, including procuring equipment, securing rights-of-way, and detailed engineering work.

EXHIBIT B

13. Deactivation of the units in 2021 could nonetheless cause transmission reliability issues and operational challenges if transmission projects to address the bridge period could not be completed by the time the units ceased operating. This would negatively impact EAP's customers and co-owners.

I declare under penalty of perjury that the foregoing statements are true and correct based on my personal knowledge and information gathered and provided to me by the Entergy Companies' personnel and consultants.

Executed this 11th day of January, 2018.

Comments of Nucor Steel – Arkansas and Nucor-Yamato Steel Company,
U.S. EPA Docket No. EPA-R06-OAR-2015-0189

COMMENTS OF NUCOR STEEL – ARKANSAS
AND NUCOR-YAMATO STEEL COMPANY

Promulgation of Air Quality Implementation Plans; State of Arkansas;
Regional Haze and Interstate Visibility Transport Federal Implementation Plan;
Proposed Rule

United States Environmental Protection Agency

Docket No. EPA-R06-OAR-2015-0189

April 8, 2015

80 Fed.Reg. 18,944

Nucor Steel- Arkansas (“NSA”) and Nucor-Yamato Steel Company (“NYS”) (collectively herein “Nucor”) submit the following comments in response to the Environmental Protection Agency’s (“EPA”) “Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Proposed Rule” in Docket No. EPA-R06-OAR-2015-0189, published at 80 Fed.Reg. 18,944 on April 8, 2015 (the “Proposed FIP”). NYS and NSA operate electric arc furnace steel mills in Mississippi County, Arkansas, which produce steel products from recycled scrap metal. As a result of mills such as NSA and NYS, Nucor Corporation is one of the largest recyclers in the

nation. The cost of electric power is a significant component of the cost of producing steel in an electric arc furnace and the costs of the control technologies required under the Proposed FIP will injure NSA and NYS by increasing the cost of electric power needed to operate their facilities.

NSA and NYS both receive electrical service from Mississippi County Electric Cooperative Corporation ("MCECC"), which is a member co-operative of Arkansas Electric Cooperative Corporation ("AECC"). AECC is either an owner or co-owner of four facilities that are subject to Best Available Retrofit Technology ("BART") determinations under EPA's Proposed FIP: Entergy's White Bluff power plant ("White Bluff"), SWEPSCO's Flint Creek power plant ("Flint Creek"), AECC's Bailey power plant ("Bailey"), and AECC's McClellan power plant ("McClellan"). AECC also is a co-owner of Entergy's Independence power plant ("Independence"), for which EPA is proposing additional emission limits and controls under the Proposed FIP. These five facilities provide a large majority of the baseload generating capacity for AECC and its member cooperatives. NSA and NYS's electric power primarily comes from AECC's electric generating resources, and NSA and NYS's electricity costs are dependent on AECC's costs of maintaining and operating those generating resources, including AECC's interest in White Bluff, Independence, and Flint Creek.

As set forth herein, NSA and NYS disagree with and object to EPA's Proposed FIP. EPA's Proposed FIP does not comply with the requirements of the Clean Air Act ("CAA") because, among other things: (a) EPA has not demonstrated that its BART determinations for White Bluff and Flint Creek and its Reasonable Progress decision for Independence are necessary, (b) EPA failed to consider relevant factors in its BART and Reasonable Progress determinations for White Bluff, Flint Creek and Independence, (c) EPA failed to consider all available control technologies in its BART and Reasonable Progress determinations for White Bluff, Flint Creek and Independence, (d) EPA's determinations on cost-effectiveness of additional controls for White Bluff, Flint Creek and Independence are not justified, are unreasonable, are inconsistent and are arbitrary and capricious, (e) EPA's determinations of visibility impacts from White Bluff, Flint Creek, Independence and the other facilities involved in EPA's Proposed FIP are unreasonable and do not support its BART and RP determinations, because the CALPUFF model is unsuitable for EPA's regulatory determinations under these circumstances; thus, EPA has not demonstrated that there is a reasonable certainty that the controls required under its BART and Reasonable Progress determinations will result in an improvement in visibility, (f) EPA has unduly relied on its cost-effectiveness calculations and has not explained how its cost-

effectiveness calculations justify its BART and Reasonable Progress determinations with respect to anticipated visibility improvements; and (g) EPA has not demonstrated that any of the sources regulated in the Proposed FIP interfere with control measures in any other state's SIP, especially given the overestimation of the CALPUFF modeling results and whether there will be any reasonably certain visibility improvement from EPA's proposed control measures; thus EPA has not demonstrated that these measures are necessary in order to comply with 42 U.S.C. §7410(a)(2)(D)(i)(II). In addition, EPA did not explain how it exercised its judgment and balanced and weighed the BART and Reasonable Progress factors in arriving at its BART and Reasonable Progress determinations.

Also, EPA has failed to fully respond to Nucor's Freedom of Information Act ("FOIA") requests and has failed to grant Nucor's request to extend the time for comments on the Proposed FIP until after EPA has fully complied with those requests.¹ Presumably, the responses to those FOIA requests would be relevant to an explanation of how EPA exercised its judgment in weighing and balancing

¹ See, Nucor FOIA request dated, March 13, 2015; letter response from L. Lane at EPA dated May 19, 2015, and Nucor's counsel's letter to EPA dated July 10, 2015, attached hereto as Exhibits 1A, 1B and 1C, respectively. Nucor reserves the right to submit additional comments in this docket after EPA has fully complied with Nucor's FOIA requests.

the BART and Reasonable Progress factors.² Finally, under the clear terms of the Clean Air Act, EPA does not have the authority to initiate this rule-making and issue its Proposed FIP, because more than two years have passed since EPA disapproved Arkansas's Regional Haze Rule State Implementation Plan.

INTRODUCTION AND BACKGROUND

EPA's disapproval of the Arkansas RHR SIP together with its decision to initiate this rule-making and impose the Proposed FIP far exceeds EPA's legal authority under the Clean Air Act. EPA's actions improperly transform the structure of the regional haze program from a state-driven program grounded in cooperative federalism to a centrally controlled, federally managed program with no meaningful role for the states, regulated entities, or in the case of electric public utilities, the end users and consumers who ultimately will bear the brunt of and have to pay for EPA's determinations. Nothing in the Clean Air Act or the

² For example, in a document dated Feb. 11, 2015 at p. 20 (attached as Exhibit 2), EPA discussed an option for the Reasonable Progress Analysis for SO₂ and NO_x controls at Independence as "No Additional Controls" since the CENRAP modeling showed that all Arkansas areas were on or below the glide path; however, this option was not included in the Federal Register notice and no explanation based on the statutory factors was given why this option was discarded.

administrative record supports EPA's determination that mandates the installation of over \$2 billion in new emission controls on public utility electric generation resources that have significant social and economic value in and to the State of Arkansas

Congress enacted the Clean Air Act's regional haze provisions with a long-term goal of returning national parks and certain scenic areas to a state of natural visibility. However, Congress realized such changes could not be fully realized immediately and adopted an approach by which States would make incremental improvements over time. In fact, EPA has approved much longer reasonable progress goals for Class I areas in the State of California. For example, EPA approved almost 300 years for the Desolation Wilderness and Mohalume Wilderness, which must achieve compliance by 2307. 76 Fed.Reg. 34,608 (June 14, 2011); 76 Fed.Reg. 13,951 (March 15, 2011). Yet, EPA is attempting in its Proposed FIP to force Arkansas to achieve compliance even earlier than the national goal of 2064.

Despite the fact that real-world, measured air quality demonstrates that Arkansas is on track to meet the visibility improvements contemplated by the

Regional Haze Rule,³ EPA has unreasonably proposed to supplant the State's authority and impose a FIP that would place additional emission control requirements on a handful of sources at significant cost notwithstanding expected further emissions reductions from levels that have achieved the desired target today. Furthermore, EPA has failed to explain how these costly emissions are reasonably certain to achieve actual visibility improvements, as required by the CAA.

Congress first adopted regional haze provisions in 1977 to establish a national goal that would address haze issues in national parks and other federal "Class I areas" by adding Section 169A to the Clean Air Act. See, 42 U.S.C. § 7491. EPA has established three primary components for a state's regional haze SIP: (1) reasonable progress goals for Class I areas in the state; (2) a long-term strategy; and (3) implementation of BART for certain stationary sources. The Clean Air Act requires states to submit SIPs that contain "emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal." 42 U.S.C. § 7491(b)(2). The

³ See, Arkansas Department of Environmental Quality, "State Implementation Plan Review for the Five-Year Regional Haze Progress Report," Revised May 2015, pp. 43, 64, attached hereto as Exhibit 3.

reasonable progress goal “is a goal and not a mandatory standard which must be achieved by a particular date.” 64 Fed. Reg. 35,714, 35,733 (July 1, 1999). Further, States have considerable discretion in establishing reasonable progress goals; for instance, the Clean Air Act “requires only that a state establish reasonable progress, not the most reasonable progress.” North Dakota v. EPA, 730 F.3d 750, 768 (8th Cir. 2013).

States are required to consider four statutory factors when establishing reasonable progress goals that are “necessary” for Class I areas. 42 U.S.C. § 7491(g)(1); 40 C.F.R. § 51.308(d)(1)(i)(A). These factors are: (1) costs of compliance; (2) the time necessary for compliance; (3) the energy and nonair quality environmental impacts of compliance; and (4) the remaining useful life of any potentially affected sources. 42 U.S.C. § 7491(g)(1). Furthermore, reasonable progress goals are “interim goals that represent incremental visibility improvement over time.” See, USEPA, “Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program,” June 1, 2007, section 1.2, p. 1-2. The “first planning period” for the Arkansas Regional Haze Rule SIP extends from 2008 to 2018.

To comply with the BART requirements, states must develop “emission limitations representing BART” for a specified set of sources. 42 U.S.C. § 7491(b)(2)(A); 40 C.F.R. § 51.308(e). BART determinations must consider five statutory factors: (1) the costs of compliance; (2) the energy and nonair quality environmental impacts of compliance; (3) any existing pollution control technology in use at the source; (4) the remaining useful life of the source; and (5) the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology. 42 U.S.C. § 7491(g)(2); *see* 40 C.F.R. § 51.308(e)(1)(ii)(A).

The Clean Air Act, including the regional haze program, is built on principles of cooperative federalism that require EPA to defer to states in developing implementation plans so long as necessary statutory requirements are met, and it sets forth specific time limits for action by both the States and EPA. EPA v. EME Homer City Generation, L.P., 134 S.Ct. 1584, 1600 (2014). EPA’s Proposed FIP ignores those limits and timelines and would impose a plan that ignores the primary implementation role given to Arkansas. Not only is EPA’s approach inconsistent with the Clean Air Act, it gives EPA power to arbitrarily substitute its own judgment for that of a state at virtually any stage of the implementation process.

As courts have recognized, the Clean Air Act was intended by Congress to be “a model of cooperative federalism.” Sierra Club v. Korleski, 681 F.3d 342, 343 (6th Cir. 2012); Michigan v. EPA, 268 F.3d 1075, 1083 (D.C. Cir. 2001); Florida Power & Light Co. v. Costle, 650 F.2d 579, 581 (5th Cir. 1981). Under this structure, Congress specifically found that “air pollution prevention ... is the primary responsibility of States and local governments.” 42 U.S.C. § 7401(a)(3). The Eighth Circuit recently noted that “the [Clean Air Act] grants states the primary role in determining the appropriate pollution controls within their borders.” North Dakota v. EPA, 730 F.3d at 760-61. Thus, “states have broad authority to determine the methods and particular control strategies they will use to achieve the statutory requirements.” BCCA Appeal Group v. EPA, 355 F.3d 817, 822 (5th Cir. 2003). Specifically, the states have “broad authority over BART determinations.” American Corn Growers v. EPA, 291 F.3d 1, 8 (D.C.Cir. 2002).

EPA’s role is limited to ensuring that the States’ implementation is consistent with the CAA. Florida Power & Light, 650 F.2d at 587 (“The great flexibility accorded the states under the Clean Air Act is ... illustrated by the sharply contrasting, narrow role to be played by EPA.”). Rather than establishing strict implementation requirements, EPA’s rule “requires States to determine the rate of progress for remedying existing impairment that is reasonable, taking into

consideration the statutory factors, and the informed input from all stakeholders.” 64 Fed. Reg. at 35,731; see also 40 C.F.R. § 51.308(d)(1)(i)(A). In its guidance to States, EPA emphasized that the regional haze rule “gives States wide latitude to determine additional control requirements” and, in applying the required statutory factors, the states “have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant.” USEPA, “Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program,” June 1, 2007, p. 4-2, 5-1 [emphasis supplied]. Thus, EPA has explained that “[a]s long as this evaluation is done adequately and the States provide a reasoned basis for their decision, EPA will defer to the state.” 77 Fed. Reg. 40,150, 40,156 (July 6, 2012).

In the Proposed FIP, however, EPA ignores these well-established principles of cooperative federalism, disregards the right of the State of Arkansas to make BART and Reasonable Progress decisions, and imposes a radically different implementation plan based on its own independent analysis. This over-reaching is contrary to the Clean Air Act and unlawful. However, even in doing so EPA is held to the same standards as state agencies to not act arbitrarily and capriciously, to make decisions based on sound reasoning, to take into account important and relevant factors, and to act within the scope of statutory authority, which includes

demonstrating that EPA's determinations are "necessary" to achieve the requirements of 42 U.S.C. §7491. EPA has not done so.

The sole purpose of the regional haze program is to address visibility impairment. See 42 U.S.C. § 7491(a)(1). It is not a health based standard, and EPA may not require emissions reductions just for sake of doing so under the guise of imperceptible visibility improvements. Consistent with this purpose, the Clean Air Act requires that EPA's BART determination take into account, among other things, the cost of compliance and the "degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology." *Id.* § 7491(g)(2) [emphasis supplied]. EPA may not require a source "to spend millions of dollars for new technology that will have no appreciable effect on haze in any Class I area." Am. Corn Growers v. EPA, 291 F.3d 1, 7 (D.C. Cir. 2002) (vacating EPA's BART determinations because EPA left open the possibility that it could require a source to install technologies even when those technologies had no appreciable effect on visibility). Yet that is precisely what EPA has done here.

1. EPA DOES NOT HAVE THE AUTHORITY TO INITIATE RULE-MAKING,
MUCH LESS ISSUE AND FINALIZE ITS PROPOSED FIP.

Section 110(c)(1) of the CAA (42 U.S.C. §7410(c)(1)) states:

The Administrator shall promulgate a Federal implementation plan at any time within 2 years after the Administrator –

- (A) Finds that a State has failed to make a required submission or finds that the plan or plan revision submitted by the State does not satisfy the minimum criteria established under section 110(k)(1)(A), or
- (B) Disapproves a State implementation plan submission in whole or in part, unless the State corrects the deficiency, and the Administrator approves the plan or plan revision before the Administrator promulgates such Federal implementation plan.

[emphasis supplied].

EPA partially disapproved the Arkansas Regional Haze SIP on March 12, 2012 (77 Fed.Reg. 14604); however, EPA did not take any action to issue a FIP during the two year period after that disapproval. Not until April 8, 2015, more than three years after EPA's disapproval of the Arkansas SIP, did EPA even publish notice of its Proposed FIP in the Federal Register (80 Fed.Reg. 18944).

The plain language of §110(c)(1) limits EPA to a two year time-limit to issue a FIP.⁴ By initiating this rule-making and issuing its Proposed FIP after that time, EPA impermissibly ignores and does not give effect to the words “within 2 years.” Statutes must be construed in a manner that gives effect to every word.

In EPA v. EME Homer City Generation, L.P., 572 U.S. ___, 134 S.Ct. 1584 (2014), the Court examined section 110(c)(1), and held that because the clear language of that section allowed EPA to file a FIP “at any time” within the two year FIP deadline, EPA did not have to first allow states to issue SIPs under the Cross-State Air Pollution Rule (“CSAPR”). The lower court had held that the CAA required EPA to give states a reasonable period of time to comply with the reductions under the CSAPR rule, but the Supreme Court reversed. The Court stated:

[T]he CAA sets a series of precise deadlines to which the States and EPA must adhere. . . . If EPA determines a SIP to be inadequate, the Agency’s mandate to replace it with a FIP is no less absolute. . . . In other words, once EPA has found a SIP inadequate, the Agency has a statutory duty to issue a FIP “at any time” within two years . . . The

⁴ EPA has previously recognized this limitation. See, 79 Fed.Reg. 29354, 29356 (May 22, 2014) (“CAA section 110(c) provides that EPA can promulgate a FIP immediately after making the finding of failure to submit a required SIP, as late as two years after making the finding, or any time in between.” [emphasis supplied]) Furthermore, EPA’s Region 6 office also recognized that the two year deadline for an Arkansas RHR FIP had passed. See, internal EPA email dated May 9, 2014, attached hereto as Exhibit 4.

D.C. Circuit, however, found an unwritten exception to this strict time prescription for SIPs aimed at implementing the Good Neighbor Provision. . . . However sensible (or not) the Court of Appeals position a reviewing court's "task is to apply the text [of the statute], not to improve upon it. . . . The Act empowers the Agency to promulgate a FIP "at any time" within the two-year limit. . . . Carving out an exception to the Act's precise deadlines, as the D.C. Circuit did, "rewrites a decades-old statute whose plain text and structure establish a clear chronology of federal and State responsibilities." The practical difficulties cited by the Court of Appeals do not justify departure from the Act's plain text . . . We "must presume that a legislature says in a statute what it means and means in a statute what it says there."

EME Homer, 134 S.Ct. at 1600-1601 (internal citations omitted).

Congress clearly intended to give the states the primary authority to make BART and Reasonable Progress decisions. American Corn Growers v. EPA, 291 F.3d 1 (D.C.Cir. 2002); North Dakota v. EPA, 730 F.3d 750 (8th Cir. 2013). In implementing SIPs, States cannot wait indefinitely for EPA to act on State submissions or to belatedly issue FIPs; consequently, in section 7410(c)(1) Congress set a two year limit on EPA's ability to issue a FIP after a SIP disapproval. The State of Arkansas has given EPA assurances that it will continue to work to address the concerns raised by EPA in its March 12, 2012 disapproval.⁵ EPA's

⁵ See, Exhibit 3, Arkansas RHR Five Year Progress Report, transmittal letter to Hon. Ron Curry, EPA, Region VI Regional Administrator.

Proposed FIP should be withdrawn so that the State of Arkansas can revise its RHR SIP in accordance with the requirements of the CAA.

2. EPA HAS NEITHER DEMONSTRATED THAT, NOR EXPLAINED WHY, ITS BART DETERMINATIONS AND REASONABLE PROGRESS DETERMINATIONS ARE "NECESSARY" FOR ARKANSAS TO MAINTAIN REASONABLE PROGRESS.

42 USC §7491 requires that Regional Haze implementation plans contain emission limits, compliance schedules and other measures, including BART, "as may be necessary to make reasonable progress" toward meeting the CAA's visibility goals. Monitoring data shows that Arkansas has made and will continue to make reasonable progress in visibility improvements even without the controls that would be required by EPA's Proposed FIP. (Ex. 3, Arkansas Five Year RHR Progress Report, 2015; Ex. 5, ICF International, "Criteria Pollutant Modeling Analysis for Arkansas" July 28, 2014, p. 20 ("The IMPROVE data indicate that the 2018 goals have been met or nearly met in 2012.")).

Additional emission reductions from coal-fired power plants in the states surrounding Arkansas and the four Class I areas addressed in the Proposed FIP will continue Arkansas visibility improvement trends. As shown by the spreadsheet

attached hereto as Ex. 6, of the sixty-eight (68) fossil-fuel electric generating units closest to Arkansas and the four Class I areas addressed in the Proposed FIP, seventeen (17) units are scheduled for or have already been retired or converted to natural gas (4.9 GW capacity), and thirty-two (32) units have had pollution control projects announced or completed since 2010 (13.9 GW capacity). Further reductions in emissions due to the effects of other regulatory programs and developments will further support Arkansas's visibility improvement trends. (See, Ex. 3, Arkansas Five Year RHR Progress Report, 2015, p. 23-34.)

As discussed in Comments 4 and 6 below, EPA's maximum modeled visibility improvements for the affected units at White Bluff, Flint Creek and Independence are less than 1dv (the threshold of visibility) for all Class I areas.⁶ This does not even take into account the known overestimation of visibility impacts in the CALPUFF model by at least five times, and the fact that these impact levels are well below the CALPUFF model's effective limit of usefulness of 2-3 dv. Given this uncertainty, EPA has not explained how installation of these controls may reasonably be anticipated to result in actual improvement in visibility, which is the purpose of 42 USC §169A and the Regional Haze Rule – not

⁶ See, Exhibit 7, Spreadsheet of Modeled Baseline Visibility Impacts and Visibility Improvements from Proposed FIP.

just reduction of emissions for the sake of doing so. National Parks Conservation Association v. EPA, No. 12-73710, 2015 WL 3559149 (9th Cir., June 9, 2015)

As the Supreme Court recently held, federal administrative agencies must engage in “reasoned decision making”, the agency’s “decreed result must be within the scope of its lawful authority” and “the process by which it reaches the result must be logical and rational.” Michigan v. EPA, 576 U.S. _____, slip op. at 5 (June 29, 2015). Although it should be apparent, the accepted meaning of the word “necessary” is “indispensable” or “absolutely needed.” Webster’s New Collegiate Dictionary, (8th Ed.) 1973. Thus, as used in 42 U.S.C. §7491 the term “necessary” means “absolutely needed.” In view of the existing and future improvements in air quality in the areas surrounding these four Class I areas, and in view of the uncertainty that EPA’s proposed BART and Reasonable Progress controls will result in actual visibility improvements, EPA has not explained nor demonstrated that its BART and Reasonable Progress determinations are “indispensable” or “absolutely needed”, i.e., that the only way Arkansas can maintain reasonable progress and achieve the visibility goals of the CAA is to install these controls. See, North Dakota v. EPA, 730 F.3d at 768. The meaning of the word “necessary” requires EPA to take these and other relevant factors into consideration in its BART and reasonable progress determinations and to

demonstrate that these controls are indispensable. EPA has not explained how it considered these and other relevant factors in reaching its determination that its BART determinations for Flint Creek and White Bluff and its Reasonable Progress determination for Independence is “absolutely necessary” either to meet the reasonable progress goals for the planning period ending on 2018, or the national goal in 2064. Michigan v. EPA, 576 U.S. ____, (June 28, 2015).

EPA’s Proposed FIP also is improper as to Independence because it adopts an individual source-based approach to setting reasonable progress goals inconsistent with the Clean Air Act. Reasonable Progress provisions are intended to address contributions from a wide range of sources that can be best addressed on a source-category basis. They are fundamentally different from other provisions such as those for BART and reasonably attributable visibility impairment (“RAVI”), which are specifically designed to address individual sources. As the Tenth Circuit recently explained, “[n]either the Clean Air Act nor the Regional Haze Rule requires source-specific analysis in the determination of reasonable progress.” WildEarth Guardians v. EPA, 770 F.3d 919, 944 (10th Cir. 2014). Instead, the Clean Air Act discusses “classes or categories of sources” that “may reasonably be anticipated to cause or contribute significantly to impairment of visibility” and directs EPA to promulgate rules to address them. 42 U.S.C. §

7491(a)(3), (b)(1). In contrast, under the Clean Air Act, BART and Reasonably Attributable Visibility Impairment ("RAVI") provisions are applied individually to "each major stationary source" meeting certain threshold criteria. *Id.* § 7491(b)(2)(A)(c). This distinction is carried over into EPA's regulations. For example, under the Regional Haze Rule, SIPs that incorporate reasonable progress goals are intended to address "regional haze." 40 C.F.R. § 51.308(d). Regional haze is defined by EPA as "visibility impairment that is caused by the emission of air pollutants from numerous sources over a wide geographic area." *Id.* § 51.301 [emphasis added]. In contrast, EPA defines BART as an "emission limitation [that] must be applied on a case-by-case basis" *Id.* Likewise, EPA explains that its RAVI provisions are designed to address "visibility impairment that is caused by the emission of air pollutants from one or a small number of sources." *Id.* Thus, EPA's regulations treat reasonable progress goals, which address emissions from a broad range of sources, differently than the BART and RAVI provisions, which address individual sources. Consequently, EPA does not have the authority and should not have established a separate Reasonable Progress control just for Independence.

3. EPA FAILED TO CONSIDER RELEVANT FACTORS IN ITS BART AND REASONABLE PROGRESS DETERMINATIONS.

EPA has approved Ark. Code Ann. §8-4-312 as part of the Arkansas infrastructure SIP pursuant to 42 USC §7410. See, 40 C.F.R. §52.170(e), which certifies EPA's approval of Ark. Code Ann. §8-4-312 – "Factors in Exercise of Commission Powers" (identified as former Arkansas Statutes Annotated §82-1936). When a State Implementation Plan is approved by the EPA, its requirements become federal law and are fully enforceable in federal court. See, e.g., Safe Air for Everyone v. United States EPA, 488 F.3d 1088, 1091 (9th Cir. 2007); Natural Res. Def. Council, Inc. v. S. Coast Air Quality Mgmt. Dist., 651 F.3d 1066, 1069 (9th Cir. 2011); El Comite Para El Bienestar De Earlimart v. Warmerdam, 539 F.3d 1062, 1066 (9th Cir. 2008); GenOn REMA, LLC v. EPA, 722 F.3d 513, 516 (3rd Cir. 2013) ("If the EPA approves the SIPs, they become enforceable as federal law."); US Magnesium, LLC v. EPA, 690 F.3d 1157, 1159 (10th Cir. 2012) ("Approved SIPs are enforceable as federal law . . ."). Thus, Ark. Code Ann. §8-4-312 is federal law for purposes of the Clean Air Act in Arkansas and it is as equally binding on EPA as it is on the Arkansas state environmental agencies. See, e.g., United States v. Cinergy Corp., 623 F. 3d 455 (7th Cir. 2015);

Sierra Club v. Ga. Power Co., 443 F.3d 1346 (11th Cir. 2006); United States v. General Motors Corp., 702 F.Supp. 133 (D.C. Tex. 1988).

Ark. Code Ann. §8-4-312 sets out several factors that must be taken into account in decisions to regulate air quality in Arkansas, including “the economic and industrial development of the state and the social and economic value of the air contamination sources,” Ark. Code Ann. §8-4-312(14). Although the Clean Air Act requires that certain factors must be “taken into consideration” in determining BART, 42 U.S.C. §7491(g)(2), and in establishing reasonable progress goals, 42 U.S.C. §7491(g)(1), the statute does not make those factors exclusive. In fact, EPA’s BART guidelines indicate that “unusual circumstances . . . [including] the economic effects of requiring the use of a given control technology” may be considered. 40 C.F.R. Part 51, Appendix Y, IV.E.3 (70 F.R. 39,104; 39,171, July 6, 2005).

EPA’s BART and Reasonable Progress determinations for Flint Creek, White Bluff and Independence will cost over \$2 Billion and will result in significant increases in electric rates over most of the State of Arkansas for residential, commercial, governmental, agricultural and industrial customers of Entergy, SWEPCO, AECC and the municipal owners of those facilities. These three sources constitute a large part of the baseload electric generation for the State of Arkansas, and an even larger proportion of the baseload generation for AECC and its member

cooperatives. Nowhere in the Proposed FIP does EPA consider the social and economic value of these sources, and the economic effects of EPA's actions.

Not only does EPA's failure to consider the economic consequences of its BART and Reasonable Progress determinations violate Ark. Code Ann. §8-4-312 as part of EPA's approved infrastructure SIP for Arkansas, it also violates the spirit and purpose of EPA's own Environmental Justice (EJ) guidelines which requires EPA to "consider the impacts of our regulatory actions on populations documented as frequently bearing the greatest burdens imposed by environmental pollution." EPA, "Guidance on Considering Environmental Justice During the Development of Regulatory Actions", May 2015, at p. 2.⁷ These same populations that EPA's EJ guidelines seek to protect would be adversely impacted by EPA's Proposed FIP. Arkansas is the second poorest state (49/50) with a median household income of \$40,768.⁸ It has the 4th highest percentage (ranked 46/50) of poverty stricken residents.⁹ The areas in Arkansas that White Bluff, Independence and Flint Creek serve have an average of 19.2% of residents living

⁷ Available at <http://www.epa.gov/environmentaljustice/resources/policy/considering-ej-in-rulemaking-guide-final.pdf>.

⁸ U.S. Census Bureau. Accessed 7/2/15. <http://quickfacts.census.gov/qfd/states/05000.html>

⁹ Id.

below the federal poverty level. Several counties in east Arkansas that are served by these facilities have more than 30% of their residents living below the federal poverty level.¹⁰

Federal data illustrates that the poorer a household is, the more that higher energy rates harm the occupants.¹¹ In 2012, families with annual pre-tax incomes of over \$50,000 spent 9% of their household budgets on energy, compared to only 5% in 2001. Those earning between \$30,000 and \$50,000 saw an even larger percentage of their budgets consumed by rising energy costs – 17% in 2012 compared to 10% in 2001. Most drastically, families making \$10,000 to \$30,000 spent 24% of their incomes on energy in 2012 compared to 14% in 2001.¹² EPA's Proposed FIP will increase electric rates even more, and amplify these economic disparities and income inequality even further. The increases in electric rates that electricity providers would charge ratepayers in order to comply with EPA's Proposed FIP will push more Arkansans deeper into poverty.

¹⁰ Information obtained by going county by county (on above website), accessed 7/2/15.

¹¹ <http://www.forbes.com/sites/realspin/2015/06/15/epa-clean-power-plan-may-do-more-harm-than-good/> Citing: http://www.americaspower.org/sites/default/files/Energy_Cost_Impacts_2012_FINAL.pdf

¹² Id.

There is an important relationship between utility rates, poverty and poor health. One study concluded that an additional regulatory cost of \$8.9 million related to electricity use causes one additional adult death, and that such impacts are highly concentrated in lower income groups and disproportionately affect certain minority groups. The study concludes that 43% of such deaths would occur in households with incomes of less than \$15,000.¹³ The higher energy prices resulting from EPA's Proposed FIP will force many Arkansans to spend an even higher percentage of their income on electric bills, leaving them less money for food, use of heating and air conditioning, paying health insurance premiums, buying medicine, transport to work, and to see their doctors. In forcing its Proposed FIP onto Arkansas, EPA has failed to consider whether it would harm thousands of Arkansans, which likely would be the poorest Arkansans.¹⁴

EPA also failed to consider whether the economic impact of its Proposed FIP costs would lead to closure or curtailment of White Bluff, Independence, or Flint Creek resulting in local adverse economic impacts, the impact of such closures or curtailment on electric grid reliability in the State of Arkansas, and the

¹³ Exhibit 8, Klein, D., and Keeney, R., "Mortality Reductions from Use of Low-Cost Coal-Fueled Power: An Analytical Framework" (December 2002).

¹⁴ See, Exhibit 23, AECC Letter dated Sept. 26, 2014 to Hon. G. McCarthy regarding the impacts of EPA's Clean Power Plan.

State of Arkansas's interest in maintaining sufficient electric generation resources within its own borders and subject to state regulation. Under EPA's 1980 BART guidance, EPA states that BART should not be so economically onerous that it brings a facility to the brink of shutdown or substantial curtailment of operations.¹⁵ This consideration is echoed in EPA's BART Guidelines, 40 C.F.R. Part 51, Appendix Y, IV.E.3 (70 F.R. 39,104, 39,171; July 6, 2005), yet EPA did not consider whether the \$2.0+ billion cost imposed by its BART and Reasonable Progress determinations would result in the shutdown or curtailment of operations at White Bluff, Flint Creek and Independence.

Under EPA's proposed Clean Power Plan, the possible impacts of the closure or curtailment of fossil-fuel electric generating units like White Bluff, Independence and Flint Creek on electric grid reliability was deemed to be an important factor, with several regional transmission organizations commenting on the adverse impacts of EPA's 111(d) plan on grid reliability.¹⁶ Yet, EPA improperly failed to consider or take into account the impacts of its Proposed FIP on electric

¹⁵ Exhibit 9, "Guidelines for Determining Best Available Retrofit Technology for Coal-Fired Power Plant and Other Stationary Sources, USEPA," November 1980, EPA 450/3-80-009b, section 2.6.3, p. 20.

¹⁶ See, Exhibits 10A, 10B, and 10C, Southwest Power Pool and Midcontinent Independent System Operator comments, Docket No. EPA-HQ-OAR-2013-0602.

grid reliability, either regionally or within the State of Arkansas as a whole, or within discrete electric service territories within the State of Arkansas.¹⁷

EPA did not consider whether its Proposed FIP would result in economic harms and negative health impacts in Arkansas. Not only are these factors “appropriate”, as indicated above they are “necessary” and required under Ark. Code Ann. §8-4-312, EPA’s own BART Guidelines, and its EJ Guidelines. “No regulation is ‘appropriate’ if it does significantly more harm than good.” Michigan v. EPA, 576 U.S. ____ (2015). EPA should consider whether its Proposed FIP “reflects the reality that too much wasteful expenditure devoted to one problem may well mean considerably fewer resources available to deal effectively with other (perhaps more serious) problems.” Michigan v. EPA, 576 U.S. ____ (2015). Expending billions of dollars for imperceptible visibility changes under these circumstances is simply not defensible, and has not been properly justified by EPA. EPA should have considered the economic impact of the Regional Haze Rule and its BART and Reasonable Progress determinations on the ratepayers who will

¹⁷ The impact of EPA’s proposed Clean Power Plan by way of closure or curtailment of operations of White Bluff, Flint Creek or Independence would also be a relevant factor in determining the costs of compliance, remaining useful life and the visibility impacts of those sources under the Regional Haze Rule statutory factors for BART and Reasonable Progress.

be paying for these expensive controls. EPA's failure to take these and other relevant factors into consideration in its BART and reasonable progress determinations is unreasonable, and is arbitrary and capricious. Michigan v. EPA, 576 U.S. _____, (June 28, 2015).

4. EPA FAILED TO CONSIDER ALL AVAILABLE CONTROL TECHNOLOGIES, INCLUDING USE OF LOW-SULFUR COAL, IN ESTABLISHING BART, AND FAILED TO PROPERLY EVALUATE VISIBILITY IMPACTS.

According to EPA's BART Guidelines, determination of BART should proceed according to the following five steps:

1. Identify all available retrofit technologies
2. Eliminate technically infeasible options
3. Evaluate control effectiveness of remaining control technologies
4. Evaluate impacts and document the results
5. Evaluate visibility impacts

80 Fed.Reg. 18944, 18949 (April 8, 2015). After this analysis is complete, the regulatory agency still must evaluate the factors and select the best alternative. 70 Fed.Reg. 39104, 39170 (July 6, 2005). EPA did not identify or evaluate all available retrofit technologies for White Bluff and Flint Creek. In

addition, while EPA may have modeled visibility impacts from the technologies that it did consider, EPA did not adequately evaluate those visibility impacts; for example, EPA did not evaluate the cost of the technology compared to the improvement in visibility as expressed in deciviews (i.e. \$/dv).¹⁸

Low sulfur coal has been used as the fuel source for White Bluff, Flint Creek and Independence for many years. When construction of White Bluff was approved by the Arkansas Public Service Commission, it required White Bluff to use low-sulfur coal instead of high sulfur coal.¹⁹ Entergy's five-factor analysis points out that the amount of sulfur in coal is the most important factor in controlling SO₂ emissions.²⁰ EPA's own documents in support of the national Regional Haze Rule indicate that use of 0.7% low-sulfur coal reduces SO₂ emissions by over 70%.²¹ The U.S. Energy Information Administration states that low-sulfur coal may reduce SO₂ emissions by up to 85%.²² EPA has approved the use of low-sulfur coal as Best Available Control Technology for purposes of its PSD

¹⁸ The \$/dv calculation is expressly approved in the BART guidelines. 70 Fed.Reg. 39104, 39170 (July 6, 2005).

¹⁹ See, Arkansas Public Service Commission Order No. 14, Docket 73-048 U (U-2488), October 11, 1974, attached hereto as Exhibit 11.

²⁰ See, Exhibit 12, Entergy Revised BART Five-Factor Analysis for White Bluff, dated October 14, 2013, included in this Docket as document 0045, p. 5-1.

²¹ See, Exhibit 13, Hawes, T., Worksheet from EPA's docket EPA-HQ-OAR-2002-0076, document number 145.

²² See, EIA December 21, 2001 forecast, attached as Exhibit 14.

regulations. In fact EPA has approved the use of low-sulfur coal as BART for a coal-fired power plant even though it determined that Dry Sorbent Injection (“DSI”) at a cost of only \$991/ton SO₂ was “cost-effective” for that plant.²³

As indicated, White Bluff, Flint Creek and Independence have been using low-sulfur coal for many years. The charts attached as Exhibits 15A and 15B show that White Bluff’s average coal sulfur content since 2009 has been in the range of .25 - .30%; but the BART analyses relied on by EPA did not identify, much less evaluate the use of low-sulfur coal as BART.²⁴ In addition, although Entergy identified DSI as an available control technology in its BART Five-Factor analysis, that control technology was never evaluated by Entergy nor by EPA, and no explanation was given as to why DSI was not evaluated.²⁵ DSI also was identified in the Flint Creek BART Five-Factor Analysis as an available control technology, but

²³ See, EPA’s Final BART determination for PPL Corrette, 77 Fed.Reg. 23988, 24031 (April 29, 12012) which approved the use of coal with a 0.3% sulfur content as BART.

²⁴ EPA admittedly relied on the BART five-factor analyses submitted by Entergy and AEP, rather than performing its own five-factor analysis. See, Technical Support Document for EPA’s Proposed Action on the Arkansas Regional Haze Federal Implementation Plan, p. 13, footnote 13, Docket document No. 0002. Neither the White Bluff nor the Flint Creek five-factor analyses identified or considered low-sulfur coal as an available technology. Even if EPA had already decided to reject low-sulfur coal as BART, that technology should have been identified and evaluated so that the public would be able to provide meaningful comments on EPA’s Proposed FIP.

²⁵ See, Exhibit 12, p. 5-2.

also was not evaluated.²⁶ Because low-sulfur coal, DSI and other potential available systems of control were not evaluated, EPA's BART analyses did not satisfy the requirements of the BART guidelines, and thus EPA's Proposed FIP should be withdrawn. North Dakota v. EPA, 730 F.3d 750, 764 (8th Cir. 2013) (EPA BART determination vacated where EPA did not consider all available control technologies).

EPA also failed to adequately evaluate the visibility impacts of the available retrofit technologies that were identified and evaluated. Although EPA modeled numeric visibility improvements from the control technologies that were evaluated using the CALPUFF model, EPA did not explain how it weighed those visibility impacts. At most, EPA stated for a particular numerical dv improvement that it was "considerable" or "significant," however, EPA did not explain how it balanced those visibility improvements against the other BART factors to determine BART.²⁷ EPA should explain how it weighed the five BART factors and

²⁶ See, Exhibit 16, AEP BART Five-Factor Analysis for Flint Creek, September 2013, p. 5-1.

²⁷ EPA failed to evaluate the cost/dv of the various control technologies. Instead EPA appeared to simply determine whether a particular control technology was "cost-effective", and then to choose a particular control technology based only on the incremental cost difference between the control technology choices, irrespective of whether any of the evaluated control technologies was reasonably certain to result in an actual improvement in visibility.

why it made the BART determinations that it did - as well as its Reasonable Progress determinations – and why those costs are reasonable in light any “reasonably certain” visibility benefits, especially given the known shortcomings of the CALPUFF model as discussed below.²⁸

5. EPA’S DECISIONS ON COST-EFFECTIVENESS ARE UNREASONABLE, DO NOT CONSIDER RELEVANT FACTORS, ARE INCONSISTENT, AND ARE ARBITRARY AND CAPRICIOUS.

EPA is requiring control technology for White Bluff SN-01, SN-02 and Flint Creek at a cost determined by the plant operators to be \$2,913/ton SO₂, \$3,355/ton SO₂, and \$3,845/ton SO₂, respectively. These figures do not include significant costs such as AFUDC that will be incurred by the owners of those facilities and that will be recoverable ultimately from rate-payers in rate making

²⁸ See, Comment 6 below.

proceedings before the Arkansas Public Service Commission.²⁹ In addition, EPA believes that the costs of controls at Independence would be similar to the costs at White Bluff.

EPA claims that such additional costs, including AFUDC, are not allowable costs under EPA's Cost Control Manual. However, EPA's Cost Control Manual does not recognize the economic and financial realities of public utility operations, and thus it ignores important factors that should be considered.³⁰ EPA does not have any special expertise in power plant construction, public utility financing, or public utility cost recovery and rate regulation; thus its cost estimates for White Bluff, Flint Creek and Independence are not entitled to deference. See, King v. Burwell, 576 U.S. ___, slip. op. at 18-19 (June 25, 2015) (where regulatory agency does not have expertise in the field, its interpretations are not subject to deference.) The ultimate cost of EPA's BART and Reasonable Progress determinations to Entergy, AEP/SWEPCO, and AECC and its member cooperatives is limited, because they will be entitled by law to recover their costs from ratepayers, regardless of whether those costs are "allowed" under EPA's Cost Control Manual. See, Ark. Code Ann.

²⁹ See, Entergy's White Bluff and AEP's Flint Creek Final BART Five Factor Analyses, attached as Exhibits 12 and 16.

³⁰ It should be noted that EPA's Cost Control Manual is just a rough guide, with an admitted error of +/- 30%. (Docket document No. 139-3, p. 1-4)

§23-4-501 (recently amended to explicitly provide for cost recovery of AFUDC under an interim rate surcharge). Thus, for purposes of White Bluff, Flint Creek and Independence, which are public utility BART sources, the proper cost to be considered in EPA's BART and Reasonable Progress determinations is the costs that the owners of White Bluff, Flint Creek and Independence will be allowed to recover from ratepayers.

AFUDC stands for "Allowance for Funds Used During Construction." AFUDC is part of the Federal Energy Regulatory Commission Uniform System of Accounts, and is utilized by both the FERC and state regulatory commissions, including the Arkansas Public Service Commission to account for construction financing costs which are added to the cost of the plant for rate recovery when the plant is put into service. AFUDC can easily amount to tens of millions of dollars. EPA also omitted other costs in its BART and Reasonable Progress determinations that the operators of White Bluff, Flint Creek and Independence will be permitted to recover in their electric rates.³¹ Another cost to ratepayers that EPA failed to take into consideration is the rate of return that will be allowed to the owners of

³¹ See, Entergy's "Response to EPA Region 6 comments on Entergy White Bluff draft BART Report, 06/10/13", Docket Doc. No. 0043, pp. 6-10; Ex. 12, Entergy's "Response to 8/21/2013 EPA Region 6 comments on White Bluff BART FFA", Docket Doc. No. 0045, pp. 2-3.

White Bluff, Flint Creek and Independence on the total allowable costs of the control technology required by EPA. Recently, Arkansas utilities have been permitted a rate of return between 4 and 6% on the total cost. The Arkansas Public Service Commission is obligated to allow public utilities to recover their actual costs, plus a reasonable return on investment, regardless of whether those costs are recognized under EPA's Cost Control Manual. Since these costs are legally allowed under Arkansas law, they are relevant factors that should have been taken into account by EPA in its BART and Reasonable Progress determinations. Michigan v. EPA, 576 U.S. ___, slip op. at 5, 14 (June 29, 2015) (unreasonable for EPA to not take into consideration relevant factors).³²

In rejecting and adjusting Entergy's cost calculations for White Bluff, it is not clear whether EPA accounted for the differential cost of low-sulfur coal in its BART analysis. Entergy's cost calculations were based on uncontrolled SO₂ emissions of 2.0 lb/MMBtu, a level much higher than the emission rate from

³²Even EPA's adjusted and proposed cost-effectiveness numbers for White Bluff, Flint Creek and Independence exceed the upper limit of EPA's projected cost-effectiveness range of \$400 - 2,000/ton SO₂ for EPA's presumptive SO₂ BART limits in support of the national Regional Haze Rule. Exhibit 17, Technical Support Document for BART, April 2005, p. 8.

White Bluff's historical use of more-expensive low-sulfur coal.³³ EPA's BART analysis requires continued use of low sulfur coal, at a level of 0.65 to 0.68 lb. SO₂/MMBtu, based on 2009-2013 data.³⁴ EPA should explain whether it took the cost difference between low-sulfur coal and high-sulfur coal into account in its BART determination, and if not, it should do so.

EPA'S BART and Reasonable Progress determinations also are inconsistent with other EPA BART determinations, which would have been evident if EPA had evaluated visibility improvements on a \$/dv basis. When evaluated on that basis, the costs of EPA's Proposed FIP are as follows:

Flint Creek	\$65,769,250/yr./dv
White Bluff 1	\$39,337,306/yr./dv
White Bluff 2	\$42,415,424/yr./dv
Independence 1	\$64,219,337/yr./dv
Independence 2	\$52,171,663/yr./dv

³³ See, Exhibits 15A and 15B, demonstrating the reduction in SO₂ emissions and coal sulfur concentrations for White Bluff in 2009-2011, compared to 2001-2003.

³⁴ 80 Fed.Reg. 18970, April 8, 2015.

Although EPA claims that the costs of its BART and Reasonable Progress determinations are justified here, in its BART determination for the Corette facility in Montana, EPA found that costs/dv of \$30,477,272 for DSI and \$50,308,300 for a semi-dry scrubber were excessive (even though EPA determined that both of those controls were “cost-effective” on a \$/ton SO₂ basis), and determined that BART constituted the low-sulfur coal already in use at that facility.³⁵ Existing use of low-sulfur coal as BART also avoids the additional energy costs and water/land impacts of scrubber technology. This is an important factor that EPA failed to consider in its analysis of the energy and nonair quality environmental impacts of compliance that must be considered. All \$/dv calculations for White Bluff, Flint Creek and Independence based on EPA’s adjusted costs are higher than the \$/dv ratio that EPA determined was not justified in its Corette BART determination. EPA has failed to explain why it did not consider use of low-sulfur coal as BART for the Arkansas facilities, and further has failed to explain how its determinations in the Proposed FIP are justified, consistent with its Corette BART determination.

³⁵ See, Exhibit 18, Comparison of Scrubber Cost-Effectiveness in Dollars per Deciview, attached hereto as Exhibit 18. See 77 Fed.Reg. 23998 (April 20, 2012), for the explanation of EPA’s BART determination for Corette.

6. EPA'S DECISIONS ON BASELINE VISIBILITY IMPACTS AND VISIBILITY IMPROVEMENTS ARE UNREASONABLE AND DO NOT SUPPORT ITS BART AND REASONABLE PROGRESS DETERMINATIONS.

a. EPA should have used realistic data for its visibility analysis

According to EPA's BART Guidance "The baseline emissions rate should represent a realistic depiction of anticipated annual emissions for the source." 40 CFR Part 51, Appendix Y, Section IV.D.4.c. However, EPA's BART and Reasonable Progress determinations do not comply with this requirement. First, EPA's use of the maximum 24-hour recorded emissions extrapolated across the three year analysis period significantly overestimates the visibility impacts from a facility. For example, from 2001 to 2003, Entergy Independence reported maximum 24-hour SO₂ emission rates of 5,463 lb/hr and 6,337 lb/hr from Unit 1 and Unit 2, respectively. However, the average daily emission rate over that same three year period (with downtime omitted) for Unit 1 and Unit 2 is 2,927 lb/hr and 3,088 lb/hr, respectively. Actual average emissions from the facility are half of what is represented in the modeling analysis.

Additionally, EPA admits in the Regional Haze Regulations and Guidelines for Best Available Retrofit Technology Determinations that modeled impacts are overstated. Specifically, EPA states that "there are other features of our

recommended modeling approach that are likely to overstate the actual visibility effects of an individual source. Most important, the simplified chemistry in the model tends to magnify the actual visibility effects of that source.” 70 Fed.Reg. 39104, 39121 (July 6, 2005). This led the EPA to its decision to use the 98th percentile of modeled visibility values, which eliminates roughly 7 days per year from the analysis. However, this approach has no rational or generally accepted scientific basis as a way to “normalize” the emissions data. Using the same example for Entergy Independence, if the maximum 7 days of each year from 2001 to 2003 is eliminated for each unit, the maximum 24-hour emissions rates across that timeframe become 4,768 lb/hr and 5,357 lb/hr at Unit 1 and Unit 2, respectively. This is still far above the actual average daily emission rate and continues to severely overestimate the reasonable amount of emissions that would occur over an extended period of time at the facility.³⁶

In addition, EPA failed to use the most recent SO₂ emissions data for the White Bluff and Flint Creek BART determinations, relying instead on continuous emissions data from 2001-2003 to establish baseline visibility impacts. EPA

³⁶ EPA’s 98th percentile approach also does not suffice to “normalize” the maximum visibility impacts, since there is no demonstrated relationship between the modeled highest visibility impacts and the highest observed visibility impacts.

should have used 2009-2011 emissions data, which Entergy specifically proposed for its White Bluff BART Five Factor Analysis, and which reflects a significant decrease in SO₂ emissions.³⁷ Because use of low-sulfur coal is an acceptable pollution control technology, it was wrong for EPA not to accept the emissions data from 2009-2011 just because use of low-sulfur coal was not required by a permit condition. North Dakota v. EPA, 730 F.3d 750, 764 (8th Cir. 2013).

b. Use of CALPUFF under these circumstances does not support EPA's determination to require additional controls at the three coal-fired power plants at a cost approaching \$2.5 Billion

i. CALPUFF overstates visibility impacts for a variety of reasons, including failure to incorporate puff-splitting and other demonstrated meteorological mechanisms

The EPA's reliance on CALPUFF modeling results to make regulatory decisions in this case is not justified due to CALPUFF's well-known overestimation of visibility impacts.³⁸ Under the circumstances here, it is highly likely that

³⁷ See Exhibits 15A and 15B, demonstrating the reduction in SO₂ emissions and coal sulfur concentrations for White Bluff in 2009-2011, compared to 2001-2003.

³⁸ Coincidentally, the EPA Administrator on July 14, 2015 signed a proposed notice to remove CALPUFF as a model for long-range transport in EPA's Guideline on Air Quality Models in Docket No. EPA-HQ-OAR-2015-0310.

CALPUFF overestimated the visibility impacts of White Bluff, Flint Creek and Independence by at least five (5) times. One component of this overestimation is the failure to incorporate the puff-splitting option within the CALPUFF model into the development of visibility results. Appendix B of the CENRAP BART Modeling Guidelines specifically recommends that the option for incorporating puff splitting in the model not be included; yet the CALPUFF User's Manual (Scire et al. 2000) states on page 2-37 that "across-puff shear is likely to be important for well-mixed puffs after stable surface flows develop in the evening" as an example of when puff splitting should be employed. While the use of puff-splitting alone does not resolve all potential issues with regard to the accuracy of the CALPUFF model, it is a component that when eliminated will cause visibility impacts to be overestimated. CALPUFF's overestimation of visibility impacts by a factor of 2-10 times under similar circumstances has been previously identified³⁹ and is described with specific reference to EPA's Proposed FIP for Arkansas in a report by Dr. Richard T. McNider.⁴⁰ Dr. McNider's report explains that the CALPUFF protocols used in the Proposed FIP fail to account for several well-known

³⁹ See, Exhibit 19, Hoffnagle, G., "Accuracy of Visibility Protocol Modeling in BART Evaluations" (June 15, 2012); EPA Docket EPA-R08-OAR-2011-0851.

⁴⁰ See, McNider, R. "Inadequacy of CALPUFF and CALMET Protocols for Visibility Impact Analysis in the Arkansas RHR FIP," July 13, 2015, attached hereto as Exhibit 20.

meteorological phenomena and processes, and causes it to overestimate visibility impacts by a factor of 2-3 times at distances between 40-100 km. At distances beyond 100 km, CALPUFF likely overestimates visibility impacts by a factor of 5-10 based on observations of plume widths at long-range.⁴¹ Among other things, this is due to the impact of plume transport during the overnight period in which the plume is distorted by wind shear resulting in a very wide plume. By not utilizing the puff-splitting option, this wind shear effect is ignored. As noted above, the developers of CALPUFF explicitly stated that puff splitting should be used if an evening transition is encountered. Because a majority of sources affected by the Proposed FIP have plume transport times that exceed 9 to 12 hours – resulting in some measure of overnight transport – the failure to account for overnight decoupling within the model likely understates plume widths by a factor of at least five and corresponding overstatement of concentrations by a similar factor. These evening transitions and associated plume distortion are a regular part of atmospheric behavior and cannot be neglected in regulatory actions assessing the cost benefits of controls.

⁴¹ White Bluff, Flint Creek and Independence are all more than 100 km from the nearest Class I area.

As described in Dr. McNider's report, the CALPUFF and CALMET protocols employed in the Proposed FIP neglect important physical behavior that control plume growth beyond a travel distance of 40-50 km. As found in observations of power plant plumes in Tennessee, wind fluctuations at a scale above boundary layer turbulence not captured in CALMET or realized in CALPUFF likely cause a plume to grow at 2 to 3 times that produced in CALPUFF. The neglect of these intermediate scales of motion is likely part of the reason the Hoffnagle report (Ex. 19) found CALPUFF to over-estimate concentrations.

The electric generating units that are the subject of the Proposed FIPs sit at distances between 100 and 400 kilometers from the closest Class I areas. Using the dates of the 98th percentile visibility impacts, transport wind speeds were found to be generally less than 3 m/s. Thus, transport times for all plumes would have exceeded 10 hours and most transport times were 15-24 hours. Thus, almost all plumes would have encountered an evening transition and overnight transport. The following table demonstrates the distance in kilometers (km) and plume transport times for White Bluff, Flint Creek, and Independence.

Travel Time at 3m/s

Receptor	Caney Creek		Upper Buffalo		Hercules Glades		Mingo	
Facility	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)
Entergy - White Bluff	176	16.3	200	18.5	266	24.6	335	31.0
Flint Creek	204	18.9	104	9.6	153	14.2	395	36.6
Entergy - Independence	270	25.0	188	17.4	186	17.2	191	17.7

Travel Time at 2m/s

Receptor	Caney Creek		Upper Buffalo		Hercules Glades		Mingo	
Facility	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)	Distance	Travel Time (hrs)
Entergy - White Bluff	176	24.4	200	27.8	266	36.9	335	46.5
Flint Creek	204	28.3	104	14.4	153	21.3	395	54.9
Entergy - Independence	270	37.5	188	26.1	186	25.8	191	26.5

This table demonstrates that the plume transport times for each facility and Class I area crosses into evening and overnight mixing zones. The choice of not including the puff splitting option for the FIP modeling means that CALPUFF most likely is underestimating the effects during these overnight hours, which results in

underestimating plume widths by a factor of five to ten, and corresponding overestimations of plume concentrations. This results in visibility impacts that are not accurate and should not be utilized to make regulatory decisions that have significant economic impacts.

EPA has acknowledged the shortcomings of CALPUFF and that it is primarily limited to use as a screening tool to evaluate dv changes of at least 2-3 dv. Indeed, the Hoffnagle report demonstrates that CALPUFF modeling has not been validated by real world observations and that the current regulatory version of CALPUFF used by EPA is outdated.⁴² Consequently, CALPUFF is not “sufficiently accurate to make determinations of deciview differences of 1 deciview.”⁴³

It is not appropriate under the circumstances here to rely on CALPUFF beyond use as a screening tool. Specifically, it is inappropriate to utilize CALPUFF as a screening tool to qualify a source as subject to BART and subsequently use it to determine a facility’s required implementation of a control technology at a significant financial cost. EPA in its final regional haze rules stated that “because of the scale of the predicted impacts from these sources, CALPUFF is an appropriate or a reasonable application to determine whether such a facility can

⁴² Hoffnagle, Exhibit 19 at p. 4.

⁴³ Hoffnagle, Exhibit 19 at p. 23.

reasonably be anticipated to cause or contribute to any impairment of visibility. In other words, to find that a source with a predicted maximum impact greater than 2 to 3 deciviews meets the contribution threshold adopted by the States does not require the degree of certainty in the results of the model that might be required for other regulatory purposes." 70 F.R. 39104, 39123; July 6, 2005; Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations; Final Rule [emphasis supplied]. For regulatory action such as evaluating the level of controls for a FIP, much more realistic modeling should be used to determine visibility impacts. For the Arkansas FIP, this should include at a minimum usage of the puff splitting option in CALPUFF. It should also include an evaluation of CALMET to ensure that its assimilation of winds at the 00Z and 12Z GMT times are not adversely impacting boundary layer decoupling and the development of inertial oscillations in the wind field. If at a minimum, the CALPUFF model results are overestimated by a factor of 5, the maximum 98th percentile baseline visibility impact for White Bluff, Flint Creek, or Independence would be lowered to a level that removes any reasonable likelihood that it would exceed 0.5 deciviews and thus even be subject to BART, much less result in visibility improvement that may be reasonably anticipated.

- ii. EPA does not explain the basis for its BART and Reasonable Progress determinations given the known limitations of the CALPUFF model under these circumstances

There has been no explanation or justification by EPA that demonstrates that the visibility impacts obtained from the CALPUFF model are precise enough to reliably differentiate results that are fractions of a deciview apart. In the Proposed FIP, the maximum visibility improvement reported for any single Class I area for the subject to BART units is 0.813 dv.⁴⁴ Not only is this overstated as discussed above, this is below even EPA's 1 dv level at which a discernible difference in visibility can be registered by a human.⁴⁵ In evaluating the significance of the modeled visibility improvements in the proposed FIP, EPA subjectively labels them as "considerable" (7 times), "significant" (1 time), and

⁴⁴ See Proposed FIP and Exhibit 7.

⁴⁵ See 62 Fed.Reg. 41138, 41145 (July 31, 1997) ("A one deciview change in haziness is a small but noticeable change in haziness under most circumstances when viewing scenes in mandatory Class I Federal areas."); 70 Fed.Reg. 39104, 39120 (July 6, 2005) (1.0 deciview is the "appropriate perceptibility threshold"); but see, Henry, R. "Just Noticeable Differences in Atmospheric Haze", J. Air and Waste Management Assoc. 52: 1238, 1243, attached hereto as Exhibit 21 ("A 1-deciview change is never noticeable.")

“meaningful” (1 time),⁴⁶ even though each of these impacts is below the admitted minimum level of visual perceptibility. EPA does not explain how these impacts can be considerable, significant or meaningful from a visibility standpoint, when these impacts are not able to be perceived.⁴⁷

If adjusted to account for the overestimation of the CALPUFF model and the distances and transport times involved in this case, the modeled visibility improvements would be even further below the 1dv perceptibility threshold. As explained in Dr. McNider’s report, based on the studies of observed plume width versus modeled plume width, dispersion results beyond 100 kilometers can be expected, at a minimum, to be overestimated by a factor of at least 5. This would bring the modeled visibility improvement results down to a level well below anything that would be observable and far below what CALPUFF can reasonably predict.

⁴⁶ “Considerable” - pp. 18952; 18959; 18959; 18966; 18972; 18978; 18994; “Significant” - p. 18994; “Meaningful” – p. 18952.

⁴⁷ To the extent EPA’s decisions in the Proposed FIP were based on “cumulative visibility benefits” or “total visibility benefits,” that is misleading, has no legal basis, and is not scientifically defensible. See, Exhibit 19, Hoffnagle Report, p. 3 (deciviews cannot be directly added or subtracted.)

EPA's visibility analysis in the Proposed FIP systematically overstates both the baseline visibility impacts of White Bluff, Flint Creek and Independence, and the visibility benefits that would result from installation of EPA's required controls.⁴⁸ EPA's Proposed FIP presumes greater accuracy and precision than is reasonable or that may be expected from CALPUFF under the circumstances here. The EPA has utilized a model that was developed as a screening method, and has improperly utilized it as a way to make regulatory determinations to establish mandatory control technologies. As indicated in the Hoffnagle and McNider reports, the errors in this model make it impossible to predict with a reasonable degree of confidence visibility changes at the levels involved, and call into question EPA's predictions of the tiny visibility benefits projected from installation of additional controls. As indicated, EPA has not validated that the results within CALPUFF align with any real-world data or observations; however, the Hoffnagle and McNider reports demonstrate that at the distances and transport times involved here, CALPUFF does not align with observed plume dispersion. EPA has failed to update its model or to address any of these deficiencies considering currently available state-of-the-art modeling science. EPA's consideration of visibility impacts is fundamentally flawed and should be withdrawn and corrected.

⁴⁸ As well as the other sources that were modeled using CALPUFF.

EPA's admission that CALPUFF is a reasonable tool to evaluate a facility's visibility impacts only if those impacts exceed 2 to 3 deciviews, combined with the inability of the model to make accurate determinations below the 1 deciview threshold of perceptibility, discredits the results of the baseline visibility analyses in the Proposed FIP, as well as the claimed level of visibility improvement that can reasonably be anticipated from EPA's BART and Reasonable Progress determinations. For these reasons, EPA has not adequately explained how the baseline and subsequent controlled visibility analyses in the Proposed FIP justify the selected control technologies.

7. EPA DOES NOT HAVE AUTHORITY TO REQUIRE TECHNOLOGY CONTROLS AT THESE SOURCES FOR THE PURPOSES OF "VISIBILITY" INTERSTATE TRANSPORT.

The good neighbor visibility provision in 42 U.S.C. 7410(a)(2)(D)(i)(II) prohibits interference with "measures" required to be included in another State's implementation plan to protect visibility. EPA has not demonstrated that any of these sources in its Proposed FIP are interfering with any visibility control measure in any other state's SIP. Nucor disagreed with EPA's determination to

disapprove the Arkansas interstate visibility transport SIP provisions submitted to EPA on April 2, 2008 based on the same reasoning.⁴⁹ In EPA's 2011 proposed decision to disapprove that SIP submission, EPA stated that the Clean Air Act requires states to prevent "sources in the state from emitting pollutants in amounts which will interfere with efforts to protect visibility in other states." 76 Fed.Reg. 53189, 64219. In its Proposed FIP in 2015, EPA states that the Arkansas SIP did not ensure that emissions from Arkansas sources "do not interfere with other states' visibility programs as required by section 110(a)(2)(D)(i)(II) of the CAA." 80 Fed.Reg. 18998, April 8, 2015. The visibility protection requirement of §110(a)(2)(D)(i)(II) does not protect against interference with either other states "efforts" or other states "programs." Unlike the language in §110(a)(2)(D)(i)(I), which prohibits emissions that contribute significantly to nonattainment or maintenance of a NAAQS in another state, the visibility protection requirement is narrower and only protects against interference with specific measures, that is, actions included in another state's plan to achieve a visibility goal. Reasonable progress goals, projected deciview improvements from regional efforts, and the

⁴⁹ Exhibit 22, Nucor's Comments in Docket EPA-R06-OAR-2008-0727 (without exhibits), December 2011.

like are goals or standards; they are not “measures” taken by or enforced by a state.

There is nothing in the record demonstrating that any of the sources in the Proposed FIP interfere with any measure included in any other state’s SIP for the purpose of protecting or improving visibility. To the extent that EPA’s Proposed interstate visibility transport FIP is not based on direct interference with a control measure in another state’s regional haze SIP (in contrast to interference with a regional haze related visibility goal), EPA’s interpretation is contrary to the clear and express language of Section 110. EPA’s interpretation also is contrary to the Clean Air Act’s clear direction that each state is to determine its own emission limits, schedules of compliance and other measures for sources in that state for purposes of visibility protection under section 169A. EPA’s interpretation would impermissibly give one state the power to control another state’s regional haze SIP decisions, including its BART and Reasonable Progress determinations.

Finally, even if the CAA’s good neighbor visibility provision required a state SIP to contain emission limits for sources that contribute to visibility impairment at a Class I area in another state, EPA has not demonstrated that any of the controls in its Proposed FIP are “necessary” for that purpose, considering based

on the uncertainty in the modeling that these controls will result in actual visibility improvements.

CONCLUSION

EPA does not have the authority to initiate rule-making on its Proposed FIP, much less finalize or issue its Proposed FIP. Furthermore, for the reasons stated above, the Proposed FIP is arbitrary and capricious, fails to consider relevant factors, and does not demonstrate reasoned rule-making, and should be withdrawn.

EXECUTIVE SUMMARY

EPA has improperly relied upon emissions modeling that projects only very small benefits in visibility (0.085 deciviews) to justify the installation of emissions control technology for nitrogen oxides (NO_x). EPA's reliance is improper for multiple reasons. The CALPUFF modeling protocol used in the analysis neglects critical factors necessary in evaluating impacts over long distances where such minute impacts are predicted. The modeled visibility benefits estimated by EPA are not only ten times smaller than the minimum amount perceptible to a human observer, but they are demonstrably much smaller than errors found in modeled-to-measured data comparisons, and thus within the margin of error for the model. Even those results are erroneous because the model relies upon faulty data and is outdated. For NO_x, the visibility model calculates dispersion and reaction of secondary NO_x products with ammonia in the atmosphere to create nitrate particles that reduce visibility; EPA has never checked the model against actual measurements of nitrates in the atmosphere. Actual measurements of nitrates show that the assumptions in the EPA modeling protocol are invalid, resulting in an overestimation of predicted impacts. EPA's model methodology predicts visibility impacts inaccurately for several reasons. First and foremost, EPA's modeling protocol assumes a constant level of ammonia in the atmosphere available to react with NO_x. In fact, ammonia results primarily from biodegradation of vegetation, which does not occur in the cold and snow-covered winter months. Further, EPA uses the model to calculate impacts at 300 km. However, independent studies have shown the model to be unreliable at predicting impacts beyond 200 km. Finally, recent studies comparing actual measurements of nitrate in the atmosphere to predicted concentrations using the model based on the EPA modeling protocol show that the model significantly overstates actual visibility impacts.

EXHIBIT C-1

I. INTRODUCTION AND BACKGROUND

a. EPA's Proposed Rule

The proposed Federal Implementation Plan for Montana (Proposed FIP) proposes to establish revised emissions limits at Colstrip Units 1 and 2 for NO_x based upon the installation of Separated Over Fire Air (SOFA) and Selective Non-Catalytic Reduction (SNCR) at those Units. As set forth in the Proposed FIP, EPA's modeling calculations predict a degree of improvement in visibility at the Parks and Wilderness Areas (Class I areas) attributable to the installation of these technologies, as well as the incremental benefit of SNCR on top of SOFA, as follows:

TABLE 1: Projected Visibility Improvements Resulting from Controls at Colstrip (in deciviews)¹

Unit 1	SOFA	SOFA+SNCR	Incremental	Distance (km)	Angle (deg)
North Absaroka WA	0.047	0.089	0.042	252	250°
Theodore Roosevelt NP	0.182	0.264	0.082	264	340°
UL Bend WA	0.164	0.249	0.085	198	50°
Washakie WA	0.052	0.077	0.025	274	225°
Yellowstone NP	0.034	0.059	0.025	279	250°
Unit 2	SOFA	SOFA+SNCR	Incremental	Distance (km)	Angle (deg)
North Absaroka WA	0.055	0.083	0.028	252	250°
Theodore Roosevelt NP	0.19	0.269	0.079	264	340°
UL Bend WA	0.185	0.269	0.084	198	50°
Washakie WA	0.063	0.089	0.026	274	225°
Yellowstone NP	0.063	0.071	0.008	279	250°

EPA's estimated incremental benefit for the installation of SNCR on top of SOFA does not exceed 0.085 deciviews for any Class I area. This report addresses the question of whether the CALPUFF model as used by the EPA protocol can reliably be used to evaluate visibility impairment differences of the magnitude represented in this table.

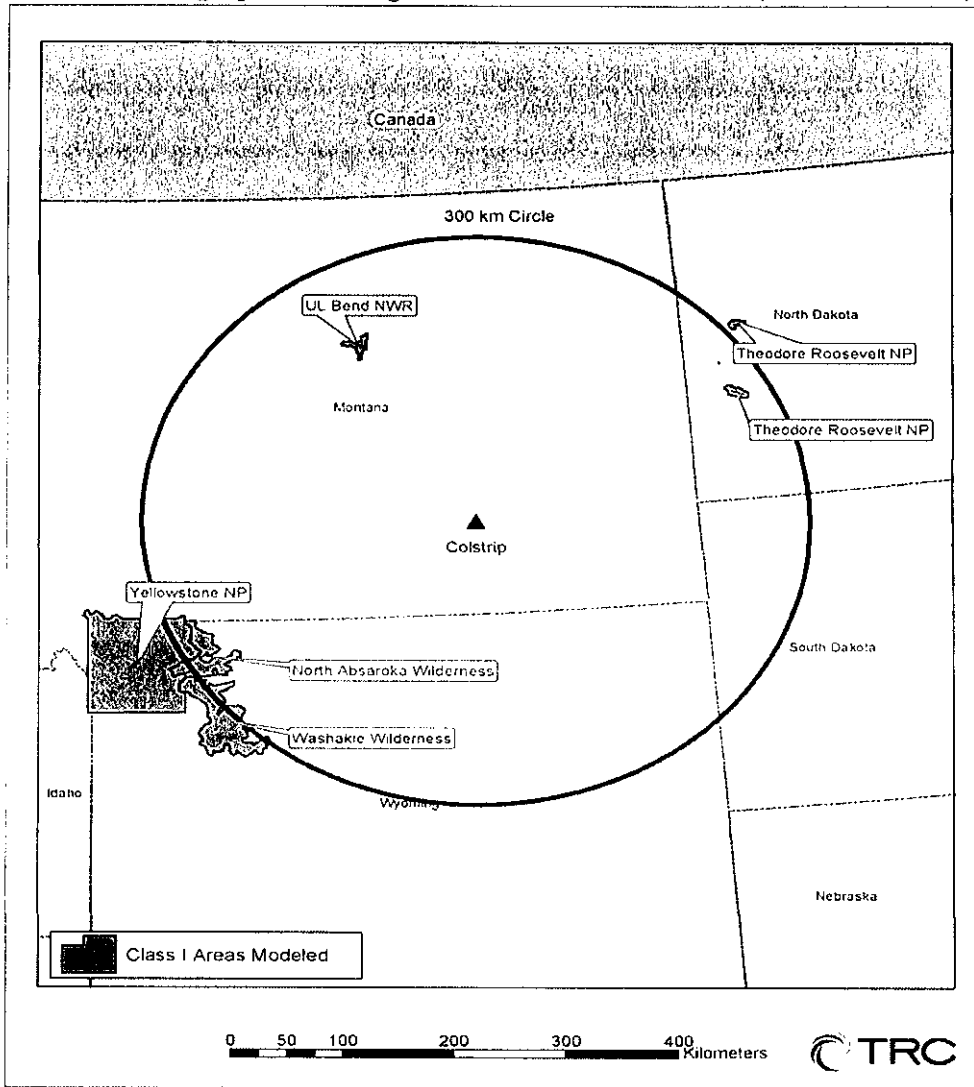

b. Class I Areas at Issue

The Class 1 areas within 300 kilometers of the Colstrip power plant are shown in Figure 1. IMPROVE measurements are taken at the South Unit of Theodore Roosevelt National Park (NP), UL Bend Wilderness Area, North Absaroka Wilderness Area and Yellowstone National Park. As shown in Figure 1, the distances to the Class I areas at issue are large and in three different wind directions.

¹ These are the values reported in the Federal Register Notice, which differ from the values reported in the University of North Carolina Modeling Report.

EXHIBIT C-1

FIGURE 1: Geographical Setting of Sources and Class I Areas (from NDDH SIP)

c. Visibility Essentials and the CALPUFF Model

To measure changes in visibility, EPA guidance requires use of sophisticated air quality computer models. In 2003, EPA adopted the CALPUFF model as the recommended air quality model for assessing long-range (> 50 km) air quality impacts. In 2005, the agency recommended that CALPUFF be used to assess the visibility improvement associated with pollution control options considered in BART analyses.

Visibility modeling, such as the CALPUFF model, involves inputting emissions of certain pollutants such as NO_x (which in and of itself does not impair visibility), and SO₂. Visibility models calculate the dispersion of the pollutants and their atmospheric reactions with other chemicals to predict the creation of light-extinguishing particles, specifically nitrates and sulfates. Based upon the movement and location of those particles in relation to Class I areas of concern, the model predicts how those emissions will affect light extinction in those locations.

EXHIBIT C-1

Modeled light extinction is calculated in deciviews. A deciview is a scale based on the concept that 1 deciview is the minimum change in visibility perceptible to a human observer. It is a logarithmic scale similar to the Richter scale for earthquakes. That means that 10 deciviews is 100 times more light extinction than 1 deciview. The relationship between light extinction, deciview and visual range is shown in Figure 2.

FIGURE 2: Relationship of Extinction, Deciviews and Visual range (NPS Introduction to Visibility)

Light extinction (the amount of photons lost to absorption and scattering) is measured in inverse megameters, as shown above. An inverse megameter is the extinction (photons of light) that would be lost due to light extinction along a path of 1 million meters (1000 kilometers or 621 miles). The relationship between deciview and inverse megameters is as follows:

$$\text{Deciviews} = 10 \text{ times } \text{Ln} (\text{extinction in inverse megameters}/10)$$

One deciview is 11.052 inverse megameters, 0.1 deciviews is 10.1 inverse megameters and zero deciview is 10 inverse megameters. Deciviews cannot be directly added or subtracted so scientists prefer to calculate extinction in inverse megameters, and convert to deciviews. Additionally, small amounts of extinction result in negative deciviews which are not useful in describing visibility reductions. Negative deciviews mean that the visual extinction is more than an order of magnitude less than the human perception level of 1 deciview.

The human perception of visibility depends on a large number of factors, including but not limited to the amount of particulate in the air, sizes of the particulate, background or vista being viewed, color, sun angle, cloud cover, relative humidity, time of the year, groundcover (snow), etc. The methodology used by EPA is greatly simplified and does not account for all of these factors. For a given particulate concentration predicted by the model, an empirical formula developed by the National Park Service is used to convert the particulate concentration to light extinction (based on an understanding of the degree of light extinction caused by the particulates in the atmosphere). NPS corrected the empirical formula to account for relative humidity, but has failed to address other factors that have a significant impact on predicted visibility.

The EPA protocol produces model results for each day in terms of deciviews. The 24-hour (midnight to midnight) average is used to be consistent with the IMPROVE measured data, which can only measure particles on a 24 hour basis. The National Park Service has traditionally categorized the visibility of a site by using the 20% worst days of extinction and the 20% best days of extinction. If 122 samples were taken at an IMPROVE site (*i.e.* one sample every third day) then there are 24 worst case days in the 20% worst and 24 best case days in the 20% best. EPA, however, requires that the model results be provided for the 98 percentile impact of a source. This is the 8th highest value in any specific year.

EXHIBIT C-1

II. SUMMARY OF CONCERNS RELATED TO EPA'S USE OF THE 2007 CALPUFF PROTOCOL

Although EPA relies primarily on the CALPUFF model in BART analyses in order to predict the emissions benefits that might result from the installation of certain control technologies, there are several fundamental, correctable problems with CALPUFF as currently used by EPA. Those problems are outlined in this section.

a. EPA's Has Not Validated Its CALPUFF Modeling Protocol

In its Proposed FIP, EPA relies upon the CALPUFF modeling protocol to make two distinct calculations: 1) the visibility impact (in deciviews) of current emissions from BART eligible sources in Montana on Class I areas; and 2) the visibility changes that are predicted to occur if emission reductions are made at those sources. EPA assumes that the results of the modeling using this protocol are accurate and sufficiently precise to make decisions about whether investments in emission controls to achieve emissions reductions from the eligible sources are warranted as BART. However, EPA has never evaluated the validity of the CALPUFF protocol to predict particulate concentrations by comparing predicted values to those actually measured at Class I areas, notwithstanding the availability of such measured data to undertake such an analysis. Without such validation against real world data, one does not know the accuracy or precision of the model to make predictions of actual visibility impacts. Rather, EPA in its use of CALPUFF relies on theoretical assumptions that have not been tested or confirmed by EPA. As set forth in Section III below, currently available data demonstrate significant inconsistencies between modeled and measured values, calling into question whether such a validation could ever be completed, and whether it is scientifically appropriate for EPA to continue to rely upon the protocol.

b. EPA's Protocol for Modeling is Outdated

Since the 2005 time frame when EPA specified the use of the CALPUFF protocol, the state-of-the-science of visibility modeling has advanced considerably. However, EPA continues to use an old version of the CALPUFF model to assess projected impacts and improvements in visibility. Indeed, although the model has been updated and improved in 2008, 2010 and 2011, EPA relies upon the 2007 version in the Montana FIP.

Indeed, CALPUFF has evolved continuously since its initial introduction; however, EPA's model approval process has not kept pace with the development process. Studies in recent years have concluded that the currently approved version of CALPUFF over-predicts particulate nitrate formation by a significant factor. As a result, significant work has been undertaken by those in the modeling community related to the creation of CALPUFF Version 6.4, which was submitted to EPA and FLMs in November 2010, and also released to the public domain (Karamchandani, et al. (2008) and Scire, et al. (2010)). CALPUFF Version 6.4 incorporates more sophisticated handling of the atmospheric chemistry of sulfate and nitrate formation, which takes into account ozone chemistry, the inorganic gas particle equilibrium, organic aerosol formation, and aqueous phase transformation. These considerations lead to more accurate reproduction of both particulate formation and visibility impact calculations. However, EPA has thus far failed to adopt this method, and instead has continued to rely upon a protocol more than 5 years old.

EXHIBIT C-1

c. EPA's Model Fails to Consider Ammonia Concentrations

In order accurately to predict visibility impacts, it is essential that a model appropriately consider the degree to which atmospheric chemistry affects the ability of gaseous NO_x to react with airborne particles and convert to particulate nitrates. These reactions depend on the availability of ammonia in the atmosphere, which reacts with NO_x products to form the light extinguishing particles. The EPA model protocol assumes that a constant amount of ammonia is present in the atmosphere to react with NO_x products at all times. However, in reality, there is a strong seasonal variation of ammonia in the atmosphere. In particular, the ambient concentrations of ammonia tend to be lowest during wintertime months, precisely the time when cold meteorological conditions are most favorable to formation of nitrate. In real world conditions, ammonia in the atmosphere comes mostly from biodegradation of vegetation, which occurs in warm months and is limited in reaching the atmosphere by snow cover. Thus, chemical reactions that require the availability of ammonia to form light extinguishing nitrate particles generally is limited, especially when there is snow cover. However, the EPA model protocol assumes that there is a constant supply of ammonia available, and thus predicts that NO_x will continue without limitation to convert into light extinguishing nitrates even when in the real world there is limited ammonia available for the reactions to take place, and thus overstates the visibility impacts that could result.

With respect to Colstrip and Montana, EPA's FIP modeling used monthly varying concentrations of ammonia from 0.98 ppb to 2.69 ppb based on data from Beulah, North Dakota. The model assumes that this amount of ammonia is available everywhere in the modeling domain and is not depleted by chemical reactions. This does not correspond to the real world availability of ammonia in the atmosphere in Montana, and has the result of vastly overestimating the visibility impacts that result from emissions of nitrates in Montana. In the winter, when the temperature favors particulate nitrate formation due to low temperatures, there is almost no ammonia available, especially during any time with snow cover. In addition, any ammonia that is available is likely preferentially to react with SO_2 , and thus does not result in as much light extinction from the formation of nitrates. In the summer, when more people use the parks, visibility impairment is also much lower because NO_x gases do not react to form nitrates in high temperatures, even when ammonia is available in the atmosphere.

Because the EPA protocol assumes that there is always ammonia available (even at monthly concentrations from 0.98 ppb to 2.69 ppb), the modeling will predict formation of nitrates even when in reality there is insufficient ammonia to do so. Corrections to these (and other) issues are available and known to EPA, and new versions of CALPUFF that use much more advanced chemical mechanisms to model the formation of particulate matter, including nitrates, have been created. Indeed, a version of the model was used by the North Dakota Department of Health and submitted to EPA (this modeling work is discussed in greater detail later in this report), which used a technique known as the "ammonia limiting method" to account for real world ammonia concentrations and the corresponding effect on visibility. However, EPA has thus far declined to use protocol updates in its modeling, including the ammonia limiting method, has failed to adopt any of its own advanced chemical mechanisms, and has not provided any justification for its failure to do so.

EXHIBIT C-1

d. CALPUFF Use Limited as to Distance

As presently used by EPA, the CALPUFF model assumes that puffs are a coherent air parcel that are transported downwind using a single puff, even though in reality the puff can span many vertical layers and horizontal grid cells with very different wind speeds and wind directions. As a result, as puffs travel with the wind away from their source, the model has a tendency to under predict dispersion and dilution of the puff. As the distance between the location of the source and the target increases, this effect compounds, resulting in increasingly over predicted puff concentrations at greater distances than exist in nature, because the EPA modeling protocol does not allow for the puff splitting effects to be included. CALPUFF allows for rigorous calculations that split the puff into multiple puffs horizontally or vertically based on the meteorological conditions encountered, which better predicts the concentrations and directions of plumes at distances beyond one hour travel times; however, EPA has not approved the use of “puff splitting” in its protocol modeling.

EPA has been aware of these limitations for long distance modeling since as early as 1998. That year, the Interagency Workgroup on Air Quality Modeling (IWAQM) studied the ability of CALPUFF to match measured data from long range transport model experiments (EPA-454/R-98-019, December 1998) (“IWAQM Report”). These experiments were done with non-reacting tracers (gases or particles), and do not test the chemistry mechanisms in the model, instead focusing specifically on the ability of the CALPUFF model to predict plume location and concentration at a distance from emissions sources. IWAQM’s results were as follows:

TABLE 2 Long Range Transport Evaluations

Experiment	Distance	Model Results Errors	
		Angle of Error	Concentration Error
Savannah River	~100 km	25 degrees	1.4 times too high
Idaho Falls	48 km	40 degrees	Two times too high
	90 km	40 degrees	Two times too high
Great Plains	100 km	5 to 20 degrees	2.5 times too high
	600 km	25 degrees	3 times too low

As demonstrated in the chart above, as the distance between the source and the target increases, concentration error increases and the model becomes increasingly inaccurate and imprecise. Due to these findings, IWAQM concluded that CALPUFF could be used to predict concentrations “200 kilometers or less” from the source, but cautioned that: “transport beyond 200 to 300 km should be done cautiously with an awareness of the likely problems involved.” (IWAQM, at page 18). Indeed, IWAQM made clear that “at receptors that were 300 km to 1000 km from the release, CALPUFF tends to overestimate surface concentrations by a factor of 3 to 4.” *Id.*

Despite this caution, and the acknowledgement of *significant* over prediction of effects, EPA continues to use the CALPUFF model to predict very small changes in concentrations of nitrates (from which visibility impacts are then calculated in deciviews) at distances from sources greater than 200 kilometers. With respect to Colstrip, EPA has relied upon the model to predict concentrations at locations up to 300 kilometers or more from the source, resulting in systematic over prediction of nitrate concentrations at target locations. However, EPA has not

EXHIBIT C-1

explained how it has mitigated or otherwise accounted for the “likely problems involved” (nor has the Agency provided any justification for why such mitigation is unnecessary).

III. MEASURED VS. MODELED RESULTS - EPA CALPUFF PROTOCOL

a. Comparison of Modeled to Measured Visibility Extinction Outside Montana

The most effective way to test the accuracy and precision of EPA modeling is to compare EPA modeled predictions to measured results. When such a comparison is made, it demonstrates that EPA’s predicted impacts do not correlate with measured impacts. Visibility impairment parameters measured at Federal Class 1 areas for over two decades, and available on the Vista website under the Interagency Monitoring of Protected Visual Environments (IMPROVE) program, measure, among other things, the total sulfate and nitrate particulates in the air over 24 hours (midnight to midnight). These measurements have formed the basis of many comparisons of the modeling protocol to the measured results. These comparisons (detailed below) across many areas of the western US independently demonstrate that the modeling protocol used in EPA’s version of CALPUFF overstates measured visibility impairment resulting from nitrates due to the issues with the protocol described above.

1. Mohave Generating Station

Prior to its closure of the Mohave Generating Station (“Mohave”), EPA’s CALPUFF model predicted that the facility was the cause of visibility impacts of 2.31 deciviews in Grand Canyon National Park. However, when the plant was closed, the visibility at IMPROVE sites in the Grand Canyon National Park as close as 90 kilometers from the facility did not show any change in nitrate concentrations or visibility impacts.

Terhorst and Berkman² analyzed the measured visibility impairment on the Grand Canyon National Park, before and after the closure of the Mohave at the end of 2005. At that time, Mohave had a maximum capacity of 1590 Mw, and was 90 kilometers west of the edge of the park. The study compared measured visibility impairment for the years 2003-2005, the three years prior to shut-down, and 2006-2008, the three years following shut-down. Terhorst and Berkman determined that the differences in measured results prior to and following shutdown for the 3 IMPROVE sites in Grand Canyon National Park, as set forth in Table 3, were so small as to be considered statistically insignificant.

TABLE 3: Before and After Mohave Results - Visibility Impairment in Deciviews

IMPROVE Monitor	2003-2005	2006-2008	Difference
Meadview	8.24	8.23	0
Indian Gardens	8.92	8.86	0.1
Hance Camp	6.54	6.61	-0.14

Meadview is the closest monitor to Mohave; Indian Gardens and Hance Camp are on the South Rim. From these data the authors concluded that the reductions in emissions due to the closing of Mohave effectively were not detectable, even though EPA modeling had previously

EXHIBIT C-1

suggested that the impact from the facility on the park was more than two times the level perceptible to the human eye. This result was not unexpected because the results of intensive tracer studies (Project MOHAVE) had shown that the “correlation between measured tracer concentrations and both particulate sulfur and light extinction were virtually nil”. One would expect the same conclusions for nitrates but Terhorst and Berkman did not study nitrates.

However, the models run according to the EPA protocol -- including CALPUFF -- predicted reductions of 1.3 to 5.0% at the western edge of the park and 0.5 to 2.6% reductions at the South Rim. Indeed, the CALPUFF model analysis³ presented to the State of Nevada in 2008 using the EPA protocol for the pre-closing emissions showed a maximum visibility impairment of 3.94 deciviews over 3 years, and a 98% visibility impairment of 2.31 deciviews for Mohave. This comparison of modeled to measured values demonstrates both the over predictive nature of EPA modeling, and diminishes its reliability to be used to justify EPA’s BART decisions.

2. Craig Station

Craig Station is about 90 kilometers west of the Mt. Zirkel Wilderness Area in northwestern Colorado. In the development of the Colorado regional haze SIP, a study⁴ was completed to evaluate the protocol model performance against IMPROVE data at Mt. Zirkel. The study compared modeled impacts from Craig Station on the 25 highest days submitted by Colorado, against IMPROVE data demonstrating the measured impact of *all* sources (including those outside the state) upon the park. The comparison is shown in the following Figure 3:

FIGURE 3: Total Extinction for Simultaneous Measured versus Modeled Days at Mount Zirkel for Craig Station: 2001-2003

As demonstrated in Figure 3, although the measured impacts at Mount Zirkel include all sources -- including mobile and point sources, and those from within and outside of the state, etc. -- the protocol model predicted that emissions from Craig Station alone would result in visibility impacts that exceeded the measured value of all sources (including Craig Station) on 14 of the 19 days, and on some of those days by significant amounts. This exceedence is particularly pronounced considering that the modeled impact of Craig Station excludes any assessment of impacts from Hayden Station, which is located between Craig and Mt. Zirkel (closer to the Class 1 Area). This analysis is based on the assumption that the Mt Zirkel IMPROVE monitor is reflective of the peak impacts within the Class I area.

The limits of the model are further emphasized through a comparison of nitrate contribution shown in Figure 4.

FIGURE 4: Nitrate Extinction: Simultaneous Measured versus Modeled days: Mount Zirkel for Craig Station 2001-2003

In this comparison, the model predicted nitrate extinction from Craig Station *alone* exceeds measured nitrate extinction from all sources combined on every one of the nineteen days. The average difference was 9.56 inverse megameters, with predicted values roughly ten times above measured. This demonstrates that the protocol model cannot be relied upon to make distinctions of 0.1 deciviews for nitrate formation.

EXHIBIT C-1

3. North Dakota SIP Protocol

In order to correct for known concerns with the protocol CALPUFF model and accurately estimate the impacts of sources within the state on Class I Areas, the North Dakota Department of Health (NDDH) prepared a State Implementation Plan (February 24, 2010)⁶ that modeled visibility impacts for all sources of emissions affecting Class I Areas within the state. Specifically, NDDH used Western Regional Air Partners (WRAP) data to calculate the impacts of sources outside of the State of North Dakota and non-utility sources inside the State, as well as CALPUFF to determine the impacts of utility sources inside the State.

In addition, in calculating the impacts of utility sources within the state, NDDH used state-of-the-art modifications to the CALPUFF model, which have been developed and demonstrated as effective since the 2005 protocols were developed. These new methods were implemented by NDDH in order to address a number of concerns with the model and improve accuracy and precision discussed above, including:

- Weather
 - Use of a newer National Weather Service forecast model to improve weather data in the system.
- Impacts from Other States
 - Use of CMAQ model to appropriately consider boundary conditions (what pollutants are coming into the grid); EPA's current protocol assumes zero impacts from outside the boundary.
- Concentrations of Ammonia
 - Use of hourly average ammonia concentrations rather than an annual average value; nitrate formation is enhanced by ammonia, and EPA's model fails to account for low ammonia concentrations in winter when most nitrates form.
 - Use of the "ammonia limiting method," which prevents the model from using the same ammonia multiple times to form nitrates. Studies of the efficacy of the ammonia limiting method in Wyoming have shown that the nitrate generation rate is three times too high when using a constant background of ammonia.⁷
- Distance and Wind
 - Use of puff splitting, which accounts for puffs spreading out in the vertical or horizontal directions as they move further from the source; EPA's modeling does not allow puff splitting.
 - Use of diffusion coefficients based on the actual measures of turbulence in the atmosphere. The protocol modeling requires use of the 1952 derived Pasquill-Gifford diffusion coefficients.

Having made these enhancements to the CALPUFF model, NDDH tested the model's performance against the measured IMPROVE data from the Theodore Roosevelt National Park (South Unit). The results of this comparison are shown in Table 4:

EXHIBIT C-1

TABLE 4: NDDH Comparison

Theodore Roosevelt South Unit	Observed ($\mu\text{g}/\text{m}^3$)	Predicted ($\mu\text{g}/\text{m}^3$)
98 th percentile	2.03	2.06
90 th percentile	1.21	1.21
Average of 20% Worst Days	1.42	1.41
Annual Average	0.53	0.53

As a demonstration of the correctness of the NDDH model results, Figure 5 shows the day by day comparisons with IMPROVE measured data at Theodore Roosevelt National Park.

FIGURE 5: Teddy Roosevelt 2002: Matching Days of Measured vs Modeled (Hybrid) Total

This comparison demonstrates that when the considerations above are taken into account in the CALPUFF modeling protocol used by EPA, measured and modeled impacts are much more closely aligned, and supports the conclusion that the problem with comparisons of the protocol modeling to measured data is the protocol itself and not the CALPUFF model. Still EPA has insisted that that the protocol model be used without any of these known enhancements to set requirements for BART. If the January 26th outlier is removed, the average difference between measured and modeled is 0.37 inverse megameters and the standard deviation is 12.6 inverse

EXHIBIT C-1

megameters. This means that even with substantial corrections to the protocol modeling, CALPUFF can get no closer than an average of 0.39 deciviews, which is well above 0.1 deciviews. The modeling, even when brought to the state-of-the-art science, is not sufficiently precise to make decisions based on differences of 0.1 deciviews.

U.S. EPA Region 8 responded to the NDDH SIP “hybrid” modeling in its Proposed FIP.⁸ Appendix B of that document contains a compilation of the protocol modeling for the various BART sources in North Dakota, and the results are cited in the proposed FIP as being accurate according to the BART Guidance and thus valid for use in the FIP. EPA’s comments do not state that the updated CALPUFF modeling used by NDDH is wrong or incorrect, but instead indicate that the modeling completed by NDDH should not be used for unspecified reasons. Also included in Appendix B is a memorandum from the Region 8 Regional Modeler, Gail Tonnesen, which asserts that NDDH’s modeling is not germane to EPA’s process because it evaluates current BART source impacts along with all other sources of visibility impairment rather than evaluating BART source impairment against the natural background visibility impairment as required by the protocol. However, the memo failed to address the validity or accuracy of NDDH’s modeling.

b. Comparison of Modeled to Measured Visibility Extinction at Colstrip

Analyses of measured versus modeled visibility impairment have been performed for Colstrip Units 1 and 2, and these comparisons demonstrate that defects in EPA’s CALPUFF model as described above raise significant concerns about EPA’s reliance upon the model to predict visibility impacts from Colstrip Units 1 and 2. Of particular significance when predicting the impacts of Colstrip is that the distance between the plant and the Class I Areas at issue are much larger than the other areas discussed above, and each of the Class I Areas allegedly affected by Colstrip is located in a different wind direction. As a result, due to the inability of the model accurately to predict impacts further than 200 kilometers from the source, EPA’s use of the model raises significant questions about the reliability of its predictions. In addition, EPA’s failure to consider ammonia availability or input the “ammonia limiting method” has particular impacts on an assessment of visibility in Montana, as it excludes consideration of seasonal snowfall (which results in very low levels of ammonia during the winter, when nitrates are most likely to form). Taken together with the other concerns set forth above, it is clear that EPA’s reliance on the model to predict visibility impacts from Colstrip on Class I areas up to 300 kilometers from the facility with its inadequate protocol is scientifically unsupportable; however, EPA has thus far failed to include (or explain its failure to include) known upgrades to the model that would increase the precision and accuracy of predicted visibility impacts.

The analyses set forth in this section compare measured visibility impacts from all sources at each of the four Class 1 areas for the years 2001-2003, and 24-hour average (midnight to midnight) modeled results for the Colstrip emissions during that period (2001-2003) (*See Regional Haze Modeling Assessment of Colstrip Generation Station*, TRC 2012). Current emissions and emissions with controls are lower than the 2001-2003 emissions. In order to assess more completely the visibility impairment contributions of the Colstrip facility, it is appropriate to run the model to take account of the hour-by-hour variations in the wind flow and track emitted haze-causing pollutants and the subsequently created haze particles.

EXHIBIT C-1

The comparisons in this section utilized the CALPUFF model with EPA Protocol. The SO₂, NO_x, and particulate matter emissions from all four Colstrip units were entered into CALPUFF using the baseline, pre-BART SIP emissions. The model yields results at each Class I Area on each day. These data were aligned with the measured data (every third day) for the purpose of the comparisons. The results of these comparisons are described for each Class 1 area separately.

The comparisons are made for the worst 20% measured days, and worst 20% modeled days (where a corresponding measurement exists). With respect to the worst 20% measured days, as depicted in the figures below, the comparison of modeled and measured impacts on those days demonstrates two points: 1) that for each of the worst 20% measured days Colstrip is a very minor contributor to overall visibility impacts; and 2) that modeled impacts from Colstrip appear to have no correlation whatsoever with the measured impacts for all sources, indicating that the model is unreliable and that Colstrip likely is not a cause of visibility impacts. With respect to the worst 20% modeled days, the comparison of measured to modeled values demonstrates that the model frequently over predicts visibility impacts, because the model regularly predicts that Colstrip alone results in greater visibility impacts than all measured sources (including Colstrip) for those days.

1. Theodore Roosevelt National Park

The comparisons of modeled and measured data for nitrates at Theodore Roosevelt National Park are depicted in the next two figures.

FIGURE 6: Nitrate Measured versus Modeled on Worst 20% Measured Days at Theodore Roosevelt IMPROVE Site

The comparison of these data demonstrates two concerns with the predicted impacts modeled by the EPA method. First, on none of the worst 20% of days are the impacts of nitrates from Colstrip *alone* a cause of more than 5 inverse megameters (-5.9 deciviews), which translates into an effect of less than zero deciviews and no perceptible impact on visibility. As a result, even as modeled under the EPA method, Colstrip cannot be determined to be a cause of visibility impairment at Theodore Roosevelt due to NO_x emissions.² Second, modeled nitrates from Colstrip do not appear to have any correlation to measured results, and predicted increases and decreases at Colstrip on certain days do not appear to have any corresponding increases or decreases in measured impacts, which would suggest that Colstrip does not in fact have any impact on the total measured nitrates in Theodore Roosevelt National Park.

This conclusion is further supported by the results when we evaluate the worst 20% modeled days (Figure 6 was the worst 20% measured days).

² The maximum measured extinction is 40.9 inverse megameters (14.1 deciviews) while the maximum modeled extinction is 4.7 inverse megameters (-7.6 deciviews) and these occur on different days. On average, the measured data is 17.7 inverse megameters (5.7 deciviews) of extinction while the average modeled extinction is about 10.1 inverse megameters (0.1 deciviews).

EXHIBIT C-1

FIGURE 7: Nitrate Measured versus Modeled on Worst 20% Modeled Days at Theodore Roosevelt IMPROVE Site

This comparison shows that on the highest two modeled days (and 9 other days) the model predicts higher nitrate extinctions at the Park from Colstrip *alone* than were actually measured from *all sources taken together*. This occurs despite the fact that it is known and recognized by EPA that there are other contributing stationary sources in Montana, in other states, and in Canada, as well as uncontrolled sources. This demonstrates that the CALPUFF model protocol leads to over prediction of nitrate extinction.

2. UL Bend Wilderness Area

At the UL Bend Wilderness Area, almost precisely the same results and the same corresponding conclusions are presented in Figures 8 and 9. On the worst case measured days (Figure 8), even impacts modeled with EPA's over predictive protocol demonstrate that Colstrip is not responsible for perceptible visibility extinction, and on the worst case modeled days (Figure 9) the nitrate contribution of Colstrip is over predicted on many days.

FIGURE 8: Nitrate Measured versus Modeled on Worst 20% Measured Days at UL Bend IMPROVE Site

The model results for these days show that the contribution of Colstrip is minimal -- no more than 5 inverse megameters (-6.9 deciviews) on each of these days.

FIGURE 9: Nitrate Measured versus Modeled on Worst 20% Modeled Days at UL Bend IMPROVE Site

There are 11 days in this comparison where the Protocol CALPUFF modeling for Colstrip alone exceeds the actual measured data for all sources.

3. North Absaroka Wilderness Area

At the North Absaroka Wilderness Area the results of the same analysis are shown in Figure 10 and 11. On the worst case measured days (Figure 10), even impacts modeled with EPA's overpredictive protocol demonstrate that Colstrip is not responsible for perceptible visibility extinction, and on the worst case modeled days (Figure 11) the nitrate contribution of Colstrip is over predicted on nine of the 20 days.

FIGURE 10: Nitrate Measured versus Modeled on Worst 20% Measured Days at North Absaroka IMPROVE Site

The same pattern emerges for North Absaroka with the exception that for one day the measured and modeled are close and for one day the modeled exceeds the measured. Again, Colstrip is the only source considered, even though we know in fact that there are other stationary and area sources that contribute emissions.

FIGURE 11: Nitrate Measured versus Modeled on Worst 20% Modeled Days at North Absaroka IMPROVE Site

At North Absaroka there are nine days when the modeled exceeds the measured.

4. Yellowstone National Park

The same analysis has been done for Yellowstone National Park and the results are presented in Figures 12 and 13. On the worst case measured days (Figure 12), even impacts modeled with EPA's over predictive protocol demonstrate that Colstrip is not responsible for perceptible visibility extinction, and on the worst case modeled days (Figure 13) the nitrate contribution of Colstrip is over predicted on many days.

FIGURE 12: Nitrate Measured versus Modeled on Worst 20% Measured Days at Yellowstone IMPROVE Site

There are only three days among the 64 worst 20% of days at Yellowstone when the Protocol Model shows more than insignificant contribution. Even on those three days the contribution is well less than 0.1 deciviews (10.1 inverse megameters).

FIGURE 13: Nitrate Measured versus Modeled on Worst 20% Modeled Days at Yellowstone IMPROVE Site

At Yellowstone there are 10 days when the modeled extinction exceeds the measured data. Again, only Colstrip emissions are considered. Thus, the modeled results for Colstrip *alone* over predict the measured nitrates on those days.

5. Comparison to 20 % Best Days

The comparisons above have focused on the Worst 20% days for the reason that the best 20% days are not very instructive about the model performance. The Best 20% modeled days have no impact at any of the individual Class I areas. That is because, on the Best 20% days, the wind is not flowing toward that Class I area and thus the model calculates zero impact. On the other hand, EPA's model continues to predict that there will be some impacts on the Park, demonstrating the inability of the model accurately to predict the impacts of wind and other factors. As an example Figure 14 is for Theodore Roosevelt National Park.

FIGURE 14: Nitrate Measured versus Modeled on Best 20% Measured Days at Theodore Roosevelt IMPROVE Site

It is important to recognize the scale of these data is all less than 1 inverse megameter. There are three days when the Protocol Model over-predicts the measured data demonstrating that the model is over predicting the impact of Colstrip because there are other sources that contribute.

FIGURE 15: Nitrate Measured versus Modeled on Best 20% Measured Days at North Absaroka IMPROVE Site

The result is the same, the model over-predicts three times and is equal to the measured on a fourth. The nitrate extinction is also very low for this site on the best days.

IV. CONCLUSIONS

The CALPUFF modeling using the EPA protocol has been demonstrated through comparison to actual data to yield over predictions from 2 to 10 times the actual measured nitrates at Class I areas across the West. This combined with EPA's use beyond the minimally reliable distance of 200 kilometers, means that the EPA modeling protocol is not sufficiently accurate to make determinations of deciview differences of 1 deciview much less 0.1 deciview.

The summary of conclusions of the comparisons set forth in this report can be described as follows:

- On the Worst 20% modeled days, the Protocol Model over predicts the measured data on enough days to conclude that the model will consistently over predict visibility based on nitrates.
- On the Worst 20% measured days the Protocol model predicts very little actual measured impact from Colstrip. This leads to the conclusion that reductions in NO_x emissions will not lead to any significant reduction in nitrate extinction at any of these Class I areas.
- Because these comparisons were done with 2001 to 2003 emissions from Colstrip and the current actual emissions are lower, the ability to affect the nitrate extinction at the Class I areas is even lower than the analyses presented here indicate.
- There are many other sources that are clearly making contributions (based on the WRAP studies), especially to the Worst 20% days. The comparison between modeled impacts from Colstrip alone versus measured impacts from *all* sources further demonstrates that the effect of reductions at Colstrip will not lead to significant improvements in nitrate extinction at any of these Class I areas.
- This analysis provides a look at the light extinction before the application of any further controls to Colstrip. After application of these controls, no real progress toward reducing light extinction at the Class I areas will be made. On top of that, this analysis still has overestimated the impact from Colstrip because the Protocol adopts methodologies that have been shown above to be incorrect, over predictive and not consistent with the measured data.

The results described above can also be summarized in the following Table.

TABLE 5: Worst Case 20% Modeled Average Nitrate Extinction

	Measured		Modeled		Modeled Percentage
	Inverse Megameters	Deciviews	Inverse Megameters	Deciviews	
Theodore Roosevelt	9.47	<0.0	2.03	<0.0	21.5%
UL Bend	5.69	<0.0	2.43	<0.0	42.7%
North Absaroka	2.00	<0.0	1.63	<0.0	81.6%
Yellowstone	1.31	<0.0	0.50	<0.0	38.2%

For the modeled worst case nitrate extinction days the measured data are very low and the modeled results show a substantially larger percentage of Colstrip impact, which reflects the over prediction in the model. In every case, the nitrate extinction is well below zero deciviews.

Control, or further control, of NO_x emissions from Colstrip will have essentially no impact (less than measurable or visible) on reducing nitrate extinction in the Class I areas.

EXECUTIVE SUMMARY

The spread rate of plumes in the atmosphere at distances beyond 10-20km are determined by physical processes which are not fully included in the CALMET/CALPUFF systems under the EPA modeling protocols employed in the Arkansas RHR FIP. For transport distances 10-100km in the real atmosphere intermediate scales of motion between those of weather systems and boundary layer turbulence determine plume spread. Plume growth studies near Nashville as part of the Southern Oxidant Study showed that inclusion of these intermediate scale motions and actual boundary layer shear produced plumes two to three times wider than when these intermediate scales are not included. These intermediate scales of motion and associated shear are not fully incorporated in models such as CALMET/CALPUFF. Evaluations by the Interagency Working Group on Air Quality modeling show that models consistently overestimate concentrations by a factor of 2-3 at distances 40km-100km and hence visibility impacts under the Arkansas FIP. This is consistent with the Nashville plume studies and points to the omission of these intermediate scales in CALMET/CALPUFF as the reason for the over-prediction of concentrations.

At distances 100-300km and beyond under light to moderate winds, plumes are likely encounter a day to night transition. As is well known in the literature, the overnight period includes decoupling of the upper part of the boundary layer which substantially distorts the plume through shear. Models that don't include this process will underestimate plume widths by factors of 5-10. The CALMET/CALPUFF systems without plume splitting ignore this fundamental process for controlling plume growth for plume travel times beyond 10-12 hours. The developers of CALPUFF also indicated that for such conditions that the plume splitting is needed. Based on transport times calculated for most of the Class I areas impacted by the energy production facilities in the Arkansas FIP, plumes will likely encounter this evening transition. Thus the modeling protocols used in the FIP are deficient in addressing these real conditions.

While tools like CALMET and CALPUFF using the restrictive EPA protocols may be useful for screening activities to test changes of 1 to 2 deciviews they are not appropriate for final regulatory actions involving billions in control cost and fractions of deciviews. The present protocols are drastically overstating the benefit of the controls because the concentrations predicted by the models impacting deciviews are being overstated substantially. In fact, the relatively small deciviews changes (especially when reduced by a factor of 2-10 due to model overestimation) are essentially insignificant and the impact of controls will be indiscernible in the real atmosphere.

EXHIBIT C-2
Exhibit 20

1. Introduction

EPA has proposed a Federal Implementation Plan (FIP) to address Regional Haze Rules for Arkansas that will entail significant costs to energy producing facilities that may exceed \$2.5 billion. It is the purpose of this brief technical report to examine whether the modeling systems used in the FIP have included the appropriate physical mechanisms that control plume growth rates at distances beyond 100km which is the distance between the energy production facilities and the visibility receptor sites.

The models that EPA used are the CALPUFF dispersion and chemistry model (Scire et al. 2000) driven by the CALMET meteorological model. These models have been developed by the air quality consulting community in conjunction with EPA to address point source air quality impacts for transport distances beyond 50km where the traditional steady state Gaussian models originally used for regulatory purposes are no longer applicable because of temporal and spatial variations in the meteorological and chemical regimes. Though they have been utilized in regulatory settings, the protocols have not been validated (Hoffnagle 2012) and the protocols and model versions used by EPA in the Arkansas FIP are out of date compared to current versions of these models and improvements made in the CALPUFF models since 2007 (see Hoffnagle 2012).

Previous attempts at evaluation of the models by the Interagency Workgroup on Air Quality Modeling (IWAQM) found consistent over-prediction (IWAQM 2005) at distances beyond 50 km. Hoffnagle 2012 also demonstrated that in evaluations of the protocols and models under the IMPROVE program that the models had significant error and overestimation of visibility impacts.

Here we describe the physical processes that are not adequately included in either the CALMET framework or the CALPUFF regulatory protocols that are likely a major source of the model and observational discrepancies found by the IWAQM and Hoffnagle . These processes are well understood by the meteorological community including the developers of CALPUFF but have not been included in the EPA BART protocols. Because they are such an endemic component of point source, impacts they cannot be ignored especially in the magnitude of the regulatory cost impacts in the Arkansas FIP.

2. Plume Growth Rates in Long-range Transport

A fundamental factor in the impact of point sources on pollutant concentration or visibility is the rate of dispersion or spread of the plume. Underestimation of plume growth rates leads to over-prediction of plume concentration and visibility impacts. Historically in near point source modeling (<20km) considerable attention was given to the role of boundary layer turbulence in controlling plume growth. (Boundary layers are the part of the atmosphere which is turbulently connected to the surface). The spatial size of turbulent fluctuations which cause mixing in the boundary layer are generally less than a kilometer or so. The size of the fluctuations is much bigger in daytime boundary layers than in nighttime boundary layers. In CALPUFF there are several different options for specifying this boundary layer turbulent diffusion. The rate of plume growth rate is dependent on both the intensity of turbulent fluctuations and their size. However, generally, the model is not very sensitive to boundary layer turbulence for long-range transport.

Theoretically (Taylor 1921, Pasquill and Smith 1983) plumes grow linearly with travel time until they reach the size of the scale of the turbulence then they slow to a growth rate proportional to time. Thus, if only boundary turbulence is controlling the plume growth then plumes would grow linearly for an hour or so then slow their growth. This behavior appears to be contained in most of the recommended turbulent options in CALPUFF.

However, observations of plume spread in the atmosphere show that plumes continue to grow linearly with time, and in fact, have periods of accelerating growth. Figure 1 shows observations of plume width of smelter plumes in Australia that could be tracked for long distances against the clean background of the Southern Hemisphere. Note that the plume width continues to grow at a least a linear rate for all travel times.

Figure 1 (left) Long-range transport experiments were made against the clean background of the Southern Hemisphere. (right) Measured plume widths continued to grow linear with time while turbulent theory says plume growth rate should slow to a $T^{1/2}$ rate. From McNider et al. 1988.

Figure 2(left) shows a simulation using a Lagrangian Particle Model (McNider et al. 1988) where only the PBL turbulence, like that used in the puff growth in CALPUFF, is employed. It shows that the plume grows much slower than observations.

Figure 2 The black symbols along the solid black line are measurements of plume width. (left) Red X indicate model plume widths using only boundary layer turbulence. (right) Red X indicate model plume widths when boundary layer shear and inertial oscillations are included. Note that the plume width with boundary layer decoupling and shear can be 10 times the width due to turbulence alone. From McNider et al. 1988.

2.1 Diurnal Boundary Layer Decoupling Overnight

So what is causing the observed plume growth to be so much larger than that due to the boundary layer turbulence alone? In the early 1980's there was a significant scientific debate between two icons of plume modeling -- Frank Gifford and Barry Smith (who worked with Frank Pasquill) on the cause of this sustained growth. Gifford argued that it was due to larger scales of motion in the atmosphere and Smith that it was due to vertical shear in the horizontal wind. McNider et al. 1988 using a sophisticated (for the time) boundary layer model and a first principal Lagrangian particle model showed that the plume growth was maintained by the decoupling of the boundary layer overnight leading to an inertial oscillation and significant distortion of the plume by wind shear

Figure 3 shows a schematic of this process in which at sunset the upper part of the boundary layer becomes decoupled as the surface stabilizes due to night time cooling. The middle part of the boundary layer goes through the well known inertial oscillation (Blackadar 1979) leading to a low level jet. The result is that the initial well mixed plume is distorted by the shear though true dispersion (reduction in local concentration) is small. However, the end result the next day, when vertical mixing brings the upper part to the ground, is a much wider and more dilute plume. If this decoupling process and resulting shear is included in the Lagrangian Particle Model a much larger plume growth which is closer to the observed plume is found. This is illustrated in the right panel of figure 2.

Figure 3 schematic of the role that boundary layer decoupling and the inertial oscillation have in distorting the plume after sunset leading to a much larger plume the next morning. From McNider et al. 1993.

This behavior is well known and also generally well handled in three-dimensional Eulerian grid models such as CMAQ and CAMx used in modern air pollution simulations employing wind field models such as WRF or the older MM5 model. This behavior is also well known to the developers of CALPUFF who make this statement in the CALPUFF Users Manual on the importance of the puff splitting option – **“Across-puff shear is likely to be important for well-mixed puffs after stable surface flows develop in the evening.”** (see CALPUFF users guide page 2-37 Scire et al. 2000)). Unfortunately, the EPA protocol for BART and RHR does not employ the puff splitting option. This is a significant fault in the model protocol for the transport distances used within the RHR simulations. The phenomena described and shown in figures 2-3 is a fundamental characteristic of the atmospheric boundary layer and occurs every day in which skies are reasonably clear and winds are light to moderate. It can only be neglected when transport distances (actually transport times are probably the most fundamental metric) are less than 50-100km.

A picture (or several pictures) is worth a thousand words. Figure 4 shows a series of snapshots of a plume released near Houston, Texas that undergoes the plume distortion described above as the boundary layer stabilizes in the evening. The plume depiction is from the Lagrangian Particle Model described in McNider et al. 1988 and the wind and turbulence moving the particles are from an MM5 model simulation. The plume release began at 6:00 AM August 25, 2000 and ends on 5:00 AM on August 26, As can be seen in the first frame at 7:00 PM the plume initially is small and transport distance limited under light winds even after 13 hours of transport and turbulent dispersal. The plume is generally well mixed vertically. However, as the sun sets and the surface cools, the boundary layer stabilizes. Now, the

inertial oscillation begins and the plume becomes more and more distorted overnight. By sunrise the plume has been spread over most of East Texas.

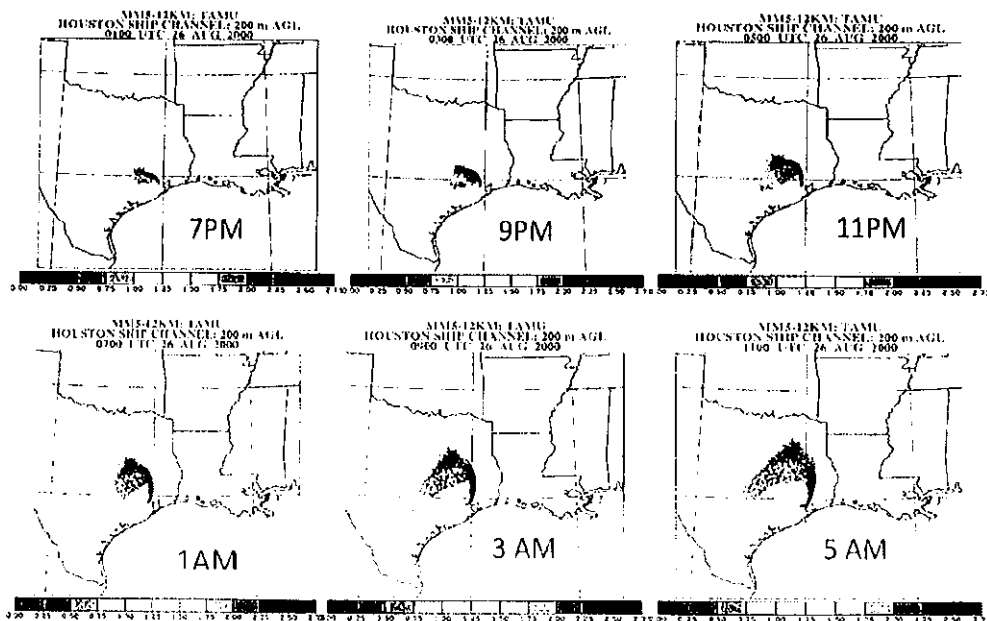

Figure 4 A series of depictions of a plume released at a site near the Houston Ship Channel with an initial release height of 200m. Pictures show the horizontal spread of the plume due to the decoupling and distortion of the plume by wind shear. Such behavior is regular characteristic of the atmospheric boundary layer but such behavior cannot be captured by CALPUFF if plume splitting is turned off. Colors give the height of the particles.

The plume behavior and decoupling shown in figure 4 is not a unique event. It is a standard part of the air pollution climatology over most of the world. The boundary layer collapse after sunset is a standard behavior when skies are reasonably clear and winds are light to moderate (see Stull 1988). For long range transport it cannot be ignored. The consistent underestimate of plume width and overestimate of concentration at longer transport distances discussed by Hoffnagle (2012) is probably in part due to these phenomena and the lack of allowing plume splitting.

The higher percentile concentrations for visibility are almost certainly going to be under relatively light to moderate winds since the dilution effect of higher winds decreases concentrations at distance (only near impacts source plume rise and building downwash might give higher concentrations at higher winds). Table 1 provides transport distances and transport times for the largest Arkansas Regional Haze Rule sources to the Class I receptors using a transport wind of 3 m/s. As can be seen, most every facility has transport times that would cross the day to night boundary before the plume reaches the receptor. Thus, neglect of the nighttime distortion and enhancement of the plume is a critical shortcoming in the FIP modeling.

Table 2. Table shows transport distances and transport times from major energy production facilities in the Arkansas FIP. Transport times on top table are based on a 3 m/s transport wind speed. Transport times in lower table are for 2 m/s. Transport wind speeds in the 98th percentile CALPUFF runs in table 1 had an average transport speed of 2.3 m/s. Note given the transport wind speed, most plumes would encounter an evening transition before reaching the receptor.

Because of the neglect of the evening transition in the modeling protocol, it is also most certain that estimates of visibility impairments are overstated in the FIP modeling. The results above in figure 2 show plume widths may be understated by a factor of up to ten if the distortion of the plume by overnight shear is omitted. Using a more complete model such as the Lagrangian Particle Model to define plume geometry and mixing or use of CALPUFF in a plume splitting mode would produce much lower visibility

EXHIBIT C-2

Exhibit 20

impacts. Given, the well-known nature of evening boundary layer decoupling and its impact on plume spread, the use of the EPA protocols neglecting puff splitting is a serious flaw in the proposed FIP.

In addition to the neglect of puff splitting in CALPUFF there is also some concern that CALMET, through its assimilation of observed wind profiles from rawinsonde balloon data, may not capture the decoupling and inertial oscillation that distorts the plume. Models such as MM5 and WRF have in general the proper physics to produce the inertial oscillation if proper turbulence parameterizations are chosen (McNider et al. 2012). Hence, the behavior seen in the Houston plume behavior described above. There is some indication that most WRF/MM5 configurations underestimate the strength of the diurnal oscillations (see Storm et al. 2009, Gupta et al. 1997 and also discussion below).

However, the CALMET model when it uses observed wind profiles to replace or adjust the boundary layer wind field may destroy the inertial oscillation that the physical model (MM5 or WRF) is correctly simulating. This is in part because of the timing of the rawinsonde balloon observations over the U.S. These observations, by world weather convention, are carried out at 00GMT and 12GMT (Greenwich Mean Time -GMT). Over the central U.S. these observations are near 5-6 AM local time and 5 -6PM local time. Thus, the inertial oscillation which is occurring overnight is not observed by the standard balloon network. Therefore use of these balloon winds to adjust the winds in CALMET from WRF or MM5 may remove this critical factor in plume growth overnight. Thus, even if plume splitting is allowed in CALPUFF there would need to be an evaluation of CALMET to ensure it is retaining this important feature.

2.2 Neglect of Intermediate Spatial and Temporal Wind Variations

The above diurnal decoupling discussion addresses a major fault in the EPA FIP protocol for long range transport where transport times exceed 9-12 hours and are likely to cross the evening transition. There is also an issue about transport times exceeding a few hours. The IWAQM report (see IWAQM 2005) indicates that even at short transport distances (50-100km) that the models underestimate plume widths and overestimates concentrations by a factor of 1.5 to 2.5. We propose here that this error is endemic to the neglect of scales of motion which are unresolved or suppressed in the CALMET/WRF framework. Figure 5 shows a schematic of the atmospheric energy spectrum that controls transport and dispersion. There are three scales of motion which control the growth rate of plumes. The first, at small scales, is the boundary turbulence. While not explicitly resolved in the models, there has been considerable work on parameterizing turbulence and the CALPUFF offers several different parameterizations which should be sufficient. The second scale of motion that controls transport and dispersion is the resolved winds in the CALMET/WRF resolution. The largest scales of motion here are the synoptic/weather scale phenomena which are also generally well done in models due to the rawinsonde observations that go into the models. However, there is an intermediate scale of motion that controls transport and dispersion at transport distances of 10km to 100km that are not well resolved in models. Figure 5 gives a depiction of the wind energy (which impacts plume dispersion and transport) that is resolved, missing and parameterized in models.

Figure 5 Schematic of the wind energy spectrum in the atmosphere. Dispersion is controlled by the scale of wind energy compared to the width of the plume. Plumes continue to grow at rates proportional to time as long as there are scales of motion of order the plume size. From Gupta et al. 1997.

Under the Southern Oxidant Study (SOS) in the Nashville field campaign there was an opportunity to use both aircraft measurements to measure plume widths and wind profilers to provide details of winds that are important to plume dispersion. Figure 6 shows the wind spectra observed by a radar profiler (see Gupta et al. 1997 for further explanation) compared to the wind spectra from an MM5 model run by EPA. It shows, as discussed above, that the model does well in capturing the synoptic scales of motion. However, the comparison shows that the model does not have near as much energy as the observations at higher frequencies such as the diurnal period. (As an aside - when the diurnal oscillation was discussed above it was indicated that models generally do well with the diurnal/inertial oscillations but here it is clear that the model diurnal signal is not as strong as the observations. This may be due too much mixing in this model run which can reduce the decoupling --see McNider et al. 2012).

Figure 6 (left) Observed wind spectra from radar profiler near Nashville. (right) Wind spectra from a MM5 model simulation. Note that the model does well at replicating the energy at synoptic/weather scales but does not have nearly the amount of energy as the observations at higher frequencies (smaller periods).

The lack of wind energy in the model at the intermediate frequencies as seen in figure 6 can have a major impact on reducing plume growth. Plume dispersion experiments were carried out using both model winds and observed profiler winds. Figure 7 (left) shows a graphical depiction of the plumes using model winds and turbulence and figure 7 (right) using observed winds and model turbulence. This shows that using the observed winds (which have scales of motion not resolved in the model) produces a wider plume. Figure 8 provides this plume width difference more quantitatively by graphing the plume width using model winds and observed winds along with aircraft observations of plume width. It is clear that the real winds which includes shear produce a much more realistic plume width.

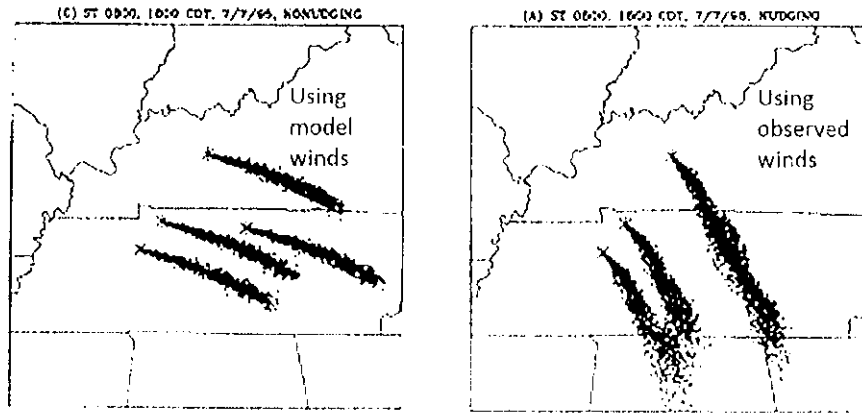

Figure 7 Depiction of modeled plumes using model winds (left) and observed winds (right). It can be seen visually that the plumes created from real winds are wider than the plumes with model winds (see Gupta et al. 1997).

Figure 8 (left) Plume widths modeled and observed for Paradise Power plant. Symbols + and - give observed plume widths based on SO₂ and NO_y aircraft measurements. Line B gives plume widths predicted from the Lagrangian Particle Model using model winds. Line A gives plume widths from the Lagrangian Particle Model using observed winds. Note that shear and high frequency energy in the real winds produce plume widths much closer to aircraft observed widths. See Gupta et al. 1997 for details. (right) Same information as left except for Cumberland Power Plant.

It can be noted that the plume widths from the real winds are nearly twice as large as the model wind plume widths at transport distances of 50-100 km. This is consistent with the IWAQM working group results that showed model concentrations were a factor of 1.5 to 2.5 times as high as observed concentrations. Thus, it is likely at 50-100km transport distances that visibility impacts may be 2-3 times over stated as compared to reality.

Such real wind behavior is likely not captured in the CALMET/CALPUFF modeling system. It should be noted that CALMET was originally designed to try to capture the motion that was unresolved in the larger scale models, however, this increased resolution largely only reflects topography and then in a very crude manner. It is likely that the winds at higher frequencies observed in the profiler data are from a combination of small topography, land use variations, cloud shading variations etc. which are not replicated in CALMET or WRF.

3. Summary and Conclusions

The models and protocols used by EPA in the Arkansas FIP neglect well known mechanisms that increase the spread rate of plumes including both diurnal decoupling and non-model resolved wind variations. The examples shown here give the physical reasons why plumes continue to grow at much greater rates than found in the CALMET/CALPUFF systems (especially the non-puff splitting option employed). The underestimation of plume spread causes an overestimation of plume concentration and associated visibility impacts of at least a factor of 2-3 for transport distances of 50-100km and a factor 5 to 10 for overnight transport.

While tools like CALPFF and CALMET using the restrictive EPA protocols may be useful for screening activities to test changes of 1 to 2 deciviews, they are not appropriate for final regulatory actions involving billions in control cost and fractions of deciviews¹. The present protocols are overstating drastically the benefit of the controls because the concentrations predicted by the models impacting deciviews are being overstated substantially. In fact, the relatively small deciviews changes (especially when reduced by a factor of 2-10 due to model overestimation) are essentially insignificant and the impact of controls will be indiscernible in the real atmosphere.

¹ 40 CFR Part 51 July 6, 2005: Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations; Final Rule page 39123Because of the scale of the predicted impacts from these sources, CALPUFF is an appropriate or a reasonable application to determine whether such a facility can reasonably be anticipated to cause an impairment of visibility. In other words, to find that a source with a predicted impact greater than 1-2 deciviews meets the contribution threshold adopted by the States does not require the degree of certainty in the results of the model that might be required for other regulatory purposes

Areas of Interest

I am an interdisciplinary scientist/mathematician. My areas of application have been quite broad, ranging from air pollution modeling, to ocean modeling, to thunderstorm initiation to model assimilation of satellite data, to crop modeling, to coupled atmosphere, ocean and ice modeling, to theoretical transport and diffusion. Particular emphasis has been on the behavior and predictability of the stable boundary layer. In relation to climate I was the initiator of the satellite temperature data set developed by John Christy and Roy Spencer. I have also been involved in the role of the stable boundary layer in climate trends

Employment History

Research Associate, Florida State University 1972-1973
Air Pollution Modeler, U. S. Environmental Protection Agency, 1973-1974
Chief of Planning and Development, Alabama Air Pollution Control Commission 1975-1983
State Climatologist, Alabama -- 1982-1999
Assistant Professor, Mathematics University of Alabama in Huntsville, 1984-1987
Associate Professor, Mathematics University of Alabama in Huntsville 1987-1992
Professor, Mathematics University of Alabama in Huntsville 1992-06/30/00
Professor, Atmospheric Science University of Alabama in Huntsville 1996-06/30/00
Interim Dean, College of Science 1998-1999
Director, Earth System Science Center, University of Alabama in Huntsville 1987-1999
Distinguished Professor of Science 1999-06/30/00
Distinguished Professor Emeritus 06/30/00-3/1/2013
Distinguished Professor Emeritus 06/30/00-3/1/2013
Executive Director, National Space Science and Technology Center (Huntsville) 2003-2004
Owner/Developer Virtual Passages, LLC -- Retailing and wholesaling a sailboat global simulator
President, Southeastern Atmospheric Modeling (SEAM), LLC
Distinguished Professor Emeritus 06/30/00-3/1/2013

Just-Noticeable Differences in Atmospheric Haze

Ronald C. Henry

Department of Civil and Environmental Engineering, University of Southern California, Los Angeles

ABSTRACT

This article examines the only available experimental data taken in the natural environment on the ability of an observer to perceive small, incremental changes in the colorfulness of objects seen through atmospheric haze and estimates an appropriate just-noticeable difference (JND) from these data. This experimentally determined threshold of perception is compared to changes in the deciview scale. Based on these experimental results, the deciview scale is found to not be uniform over a wide range of visibility conditions, as has been previously claimed. In addition, a 1-deciview change never produces a perceptible change in haze, as defined by a 95% probability of producing a measurable change in the colorfulness of an object seen through the haze.

INTRODUCTION

Section 169A of the Clean Air Act sets a national goal of protecting visibility in national parks and other pristine areas. Under regulations promulgated in 1980, the U.S. Environmental Protection Agency (EPA) has taken specific regulatory action to protect visibility in the Grand Canyon National Park by reducing emissions of sulfur dioxide from the Navajo Electric Generating Station near the eastern end of the Grand Canyon and from the Mohave Power Plant at the western end. However, current concerns about visibility degradation stem from regional haze that is difficult or impossible to attribute to individual sources of air pollution. This issue is addressed by regional haze regulations that set a goal of making reasonable

progress toward improving regional visibility in five-year increments, leading to the attainment of "natural conditions" by 2064.¹ Progress is to be measured by an innovative visibility metric for regulatory purposes known as the deciview,² used instead of visual range or other visibility metrics because it "expresses uniform changes in haziness in terms of common increments across the entire range of visibility conditions, from pristine to extremely hazy conditions."¹ One goal of this article is to assess this and other claims about the deciview scale in light of actual measurements of the perception of haziness. Since the deciview scale is meant to quantify small, just-noticeable differences (JNDs) in visibility, a review of the basic concepts of thresholds and JNDs is given.

Perceptual Threshold Concepts

For all the senses, thresholds are necessary—otherwise we would be constantly distracted by small, inconsequential changes in the environment. A background of random noise, some from the environment and some produced inside our own sensory organs, would make it next to impossible to form a stable view of the world. Our vision would be like the grainy, speckled images produced by night vision cameras. On a more basic scientific level, the study of thresholds of the senses has led to a deeper understanding of sensory physiology and how our vision and other senses function. For this reason, virtually all studies of thresholds of vision have been carried out under controlled laboratory conditions.

Since laboratory conditions seldom mimic the natural environment, thresholds so determined are generally not useful in predicting perception in the complex natural world. As an example of the drastic effect that experimental conditions can have on perception, consider an experiment to determine the ability of an observer to perceive the difference in the length of two strings—or to put it another way, to determine the threshold for perception of the difference in the length of two strings, or the JND. If the two strings are widely separated when presented to the observer, the threshold will be much greater than if the two strings are presented side by side. The visual equivalent of this is the use of a split image to determine the ability to distinguish color. If two colors are seen as two halves of a disk, the JND is very small, but if one

IMPLICATIONS

Current regulations use the deciview to quantify a perceptible change in regional haze. Based on the results of this article, changes in atmospheric extinction required to meet regional haze regulations calculated using deciviews would probably be too small, sometimes much too small. In addition, these regulations require that progress be assessed over five-year intervals. In this way, the burden of reducing emissions is spread evenly over many years. However, since deciviews are not uniform in perception, it may be that the actual improvement in visibility will not be uniform.

color is presented as a full disk, followed a few seconds later by the other color, the JND will be much larger. The topic of the background on which the colors are seen is also important (e.g., if it is black or a complex scene). In general, many conditions influence thresholds; for this reason, the results of laboratory experiments should be applied with great caution to the natural environment. Thus, this article will report and analyze data taken in a unique experiment in the natural environment with a goal of determining a JND in atmospheric haze.

In the above discussion, the terms "threshold" and "JND" have been freely used, but not defined. The naïve definition of a threshold or JND is clear: It is the smallest amount, or change in, a physical stimulus that is detectable. Ideally, a 1-JND change in a stimulus such as contrast or color would always result in the observer seeing a change, and anything less would not. Of course, the senses do not work in this simple on-off manner. In actuality, as the change in the physical stimulus increases, the probability that the observer will detect the change increases as well. Thus, thresholds and JNDs have always been defined by a probability of detection. Furthermore, the sensitivity of people's senses varies from person to person and during a person's life. Even if each person had a single, idealized threshold, the response of the general population would be best described by a probability of detection.

Repeated matching by the method of adjustments is one of the oldest methods of determining a JND. Falmagne³ described this and other methods to quantify perception. Briefly, the observer is shown a target color and a variable test color and is asked to adjust the test color until it matches the target. Taking random starting points, the matching procedure is repeated as often as is practical. Since the observer has judged the matching color to be the same as the target color, the variability in the matches is a measure of a JND around the target. The standard deviation of the matches is one measure of this variability that is often used; another is the difference between the 75th and the 25th percentile of the match distribution. The method of adjustments has been replaced in laboratory studies by methods that give less control to the observer and more to the researcher and therefore improve the reproducibility of the results (unfortunately, these methods are impractical for field studies). However, JNDs are still defined by some measure related to the probability of detection. The final determination of the value of a JND or threshold is really dependent on how the measurements are made and how the data are interpreted. For the experimental data used in this article, the method of adjustments was used and a JND related to the standard deviation of repeated matches was defined.

Atmospheric Visibility Concepts

In the classical theory of atmospheric visibility, the threshold of contrast perception, that is, the threshold for perception of a large, dark object on the horizon, is assumed to be 2%.⁴ This number is somewhat arbitrary. The Federal Aviation Administration (FAA) has taken the more conservative value of 5.5% as a contrast threshold for the definition of visual range, presumably because approaching aircraft seen from a cockpit are usually neither large nor dark. The common formula for visual range, using the 2% threshold, is

$$V_R = \frac{-\ln(0.02)}{b_{ext}} = \frac{3.9}{b_{ext}} \quad (1)$$

where b_{ext} is the extinction coefficient of the atmosphere, which is assumed to be homogeneous. The extinction coefficient in the denominator of the formula can be thought of as the fraction of light that is lost as it traverses 1 m of air. For completely clear air, b_{ext} has a value of about $10 \times 10^{-6} \text{ m}^{-1}$ or 10 Mm^{-1} , or a visual range of about 390 km. More typically, particles in the air usually increase the extinction coefficient to 150–300 Mm^{-1} or more. Typical visual ranges are about 10 km in the eastern United States and 50 km or more in the western United States. Closely related to b_{ext} and visual range is the more general concept of optical depth. For a target at a distance x , this is defined as $x b_{ext}$. It is dimensionless; if b_{ext} is held constant it represents distance, and if the distance is constant, it represents changes in b_{ext} . From eq 1, the visual range corresponds to an optical depth of 3.9, and a distance of about one quarter of the visual range is equivalent to an optical depth of 1.

Despite lacking a firm psychophysical or experimental basis, the visual range defined by the 2% threshold has stood the test of time. However, while visual range has proven to be a good surrogate for atmospheric visibility for the aviation community, it is of limited value in addressing the concerns of the air quality community. Unlike aviation, where poor visibility is of greatest interest, the air quality community is primarily concerned with relatively small changes in good visibility. Pitchford and Malm² have proposed the deciview as a visibility indicator more suited to air quality regulations. If the extinction coefficient is given in Mm^{-1} , then deciview is defined as

$$v = 10 \ln(b_{ext} / 10) \quad (2)$$

Current regional haze visibility regulations state that:

- (1) A 1-deciview change in haziness is a small, but noticeable, change in haziness under most circumstances when viewing scenes in Class I areas.
- (2) Deciview units are uniform in perception over a wide range of visibility conditions; that is, a 1-deciview change is just perceptible regardless of the visibility conditions.¹

The next section describes a color matching experiment in the Great Smoky Mountains National Park. The results of this experiment are used to estimate a just-noticeable change in haze based on color perception. The validity of the claims for deciviews will be evaluated by comparison to experimental estimates of JNDs.

EXPERIMENTAL DATA

During summer 1995, a group of researchers from universities, government agencies, and private companies conducted the SouthEast Aerosol and Visibility Study (SEAVS) in the Great Smoky Mountains National Park. The SEAVS focused largely on aerosol composition,⁵ airborne particle size distribution,⁷ and the role of water in the aerosol.¹¹ However, the SEAVS had a number of other aspects, including a study of the perception of color through atmospheric haze.¹² The methods and primary results of the color perception study are described below.

The perceived colors of natural targets were quantified by color matching using a specially constructed visual colorimeter.¹³ An observer looked at some scene element, such as a barn or green field, with one eye. The observer looked with the other eye in the visual colorimeter at a color spot, which the observer adjusted to match the color of the target. The perceived color was recorded as the amount of red, green, and blue light in the color match. At the same time, the spectrum of the light coming from the target was measured by a telespectroradiometer. A color appearance model was applied to produce measures of the perceived color as recorded by the visual colorimeter and as calculated from the spectrum.¹⁴

Of most interest here are the hue and colorfulness. The hue is what most people call the color—red, green, blue, yellow, and so on. It is quantified as a mixture of pure red, green, blue, or yellow lights. The colorfulness is the degree to which the hue is expressed; it is similar to the concept of saturation. A deep red color would have a colorfulness of about 100, while a colorfulness of 10 or less is almost achromatic (i.e., white or gray).

Two observers (Mahadev and Urquito) made color matches of a set of natural targets during the SEAVS. These observers were both males in their 20s with normal color vision. Each had received extensive training in color matching using the visual colorimeter. The scattering coefficient of the atmosphere was measured by a nearby nephelometer; particle absorption was small and its contribution to the extinction coefficient ignored. The full details of the experiment are found in Mahadev.¹⁵

The perception study found that viewing through a semitransparent atmosphere affected the perception of hue and colorfulness in a highly nonlinear way. The eye appeared to split the light coming from the target into two parts, the haze and the target. The result was that as

the haze increased, the hue of the target as seen by the observer remained constant. However, because the increasing haze scattered more light into the sight path, the hue calculated from the spectrum became bluer. To the observer, the main effect of haze was to decrease the perceived colorfulness. Furthermore, the decrease in colorfulness seemed to be exponential with optical depth (optical depth is the dimensionless product of the extinction coefficient and distance):

$$M(\tau) = M_0 \exp(-\tau) \quad (3)$$

where $M(\tau)$ is the colorfulness of the object at optical depth τ and M_0 is the colorfulness at zero optical depth (i.e., no haze). M_0 is also known as the inherent colorfulness. The colorfulness of the horizon was assumed to be small enough to be taken as zero—the horizon was perceived to be white. This result implies that a JND in colorfulness can be taken to be a JND in haze.

JND in Colorfulness

Estimates of JNDs in colorfulness were based on sets of repeated color matches made during periods when the observing conditions (cloud cover, haze level, and lighting) were judged to be constant or nearly so. Observer Urquito made six sets of repeated matches.¹⁵ Figure 1 is a plot of all the repeated observations of the colorfulness of the red barn roof made by this observer versus optical depth. The exponential fit given by eq 1 is fairly good ($R^2 = 0.68$). The error bars in the figure are twice the standard deviation given in Table 1. They show that one set

Figure 1. Colorfulness vs. optical depth for observer Urquito for repeated observations of the red barn roof. The line is an exponential fit as in eq 1, and the error bars are two times the standard deviation given in Table 2.

of repeated measurements had colorfulness values that deviated much more than 2 sigma from the exponential line. However, the spread of these values about the mean was about the same as other observations for the same optical depth. This shows that the variability in the colorfulness numbers is not affected by systematic observer bias in the average colorfulness, and that the variability will be used to define the JND. The observations of the same target by the other observer are discussed in detail below.

Table 1 gives the results of five sets of repeated matches by observer Mahadev for the roof of a red barn about 3.5 km distant. Table 1 is sorted by the extinction coefficient so that one can easily see that the perceived hue did not change with increasing haze, but that the hue derived from the spectrum changed from red to blue. Colorfulness had the opposite behavior; the perceived values decreased with increasing haze and the values from the spectrum stayed about the same. Two-way

analysis of variance was applied to estimate the random error in the sets of repeated measurements in Table 1. This analysis was repeated for both observers' matches of five additional natural targets. The results are given in Table 2. The standard deviation for both observers was 2.05, as calculated from the average of the variances. Although viewing conditions were chosen to be constant, some of this variability was due to small changes in atmospheric conditions.

Based on these results, one can define the JND in colorfulness in many ways. One appropriate definition for this application is based on the following thought experiment. An observer matches a target with the visual colorimeter and determines the colorfulness to be C_1 . The extinction coefficient of the atmosphere is decreased, so the colorfulness of the target is increased by an amount ΔC .

The observer matches the target again to get the new colorfulness C_2 . A JND is defined as the value of ΔC that gives a 95% probability that $C_2 - C_1 > 0$. Assume that C_1 and C_2 are normal random variables with standard deviation s and means C_0 and $C_0 + \Delta C$, respectively (statistical analysis of the SEAVS color matching data confirms that this is a good assumption). Then $C_2 - C_1$ is a normal random variable with mean ΔC and standard deviation $2^{1/2}\sigma$. The value of ΔC needed to ensure a 95% probability that $C_1 - C_2 > 0$ is given by $2^{1/2}\sigma F(0.95)$, where $F(0.95)$ is the inverse of the cumulative standard normal distribution and is equal to 1.645. Thus, the colorfulness JND is taken to be $2^{1/2}\sigma F(0.95) = 2.326\sigma$. From Table 2, using the data for both observers gives $\sigma = 2.05$, and a 1 colorfulness JND is 4.8. This value of σ includes the effects of small random variations in natural illumination, which should be included for this application because they are inevitably present, but makes the value of a colorfulness JND a bit larger than it would be otherwise.

Table 2. Standard deviations of colorfulness for repeated matches of natural targets.

Target	Observer		Distance (km)
	M	U

Deciviews and Colorfulness JNDs

Relationships between colorfulness, deciviews, and optical depth are derived below; these will be applied to test the validity of the properties of deciviews given in the regional haze regulations.

From eqs 2 and 3, an expression for deciviews v as a function of colorfulness M is derived:

$$v = 10 \ln \left(-\frac{1}{10x} \ln \left(\frac{M}{M_0} \right) \right) \quad (4)$$

For a given optical depth and inherent colorfulness, the equations above were used to calculate the change in deciviews needed to give a 1-JND increase in colorfulness, using 4.8 as a JND. Figure 2 is a plot of the results as a function of optical depth for objects with three levels of inherent colorfulness. These levels of inherent colorfulness represent a reasonable range for natural targets.¹² As might be expected, more colorful objects are more sensitive to changes in atmospheric haze. Perhaps unexpectedly, the figure shows that landscape features at a distance corresponding to an optical depth of 1–2 are the most sensitive to changes in extinction as measured by deciviews. This range corresponds to one quarter to one half of the visual range. Landscape features outside this range are much less sensitive to changes in haze. If the deciview scale were perceptually uniform, as claimed in the regional haze rules, then the lines in the figure would be horizontal, or at least approximately so. However, the change in deciviews needed to produce a 1-JND change in colorfulness varied a great deal with optical depth and inherent colorfulness. The figure also shows that a 1-JND change in colorfulness always requires more than a 1-deciview change, sometimes much more.

DISCUSSION AND CONCLUSIONS

Regional atmospheric haze affects visibility by producing a visible haze layer that limits the visual range, reduces

Figure 2. Change in deciviews needed to produce a just-noticeable increase in colorfulness for objects with an inherent colorfulness of 25, 50, and 75. The horizontal dashed dotted line represents what would be expected if a 1-deciview change were actually a uniform measure of haze perception.

contrast, and decreases the colorfulness of objects seen through the haze. Of these three effects of haze, the decrease in colorfulness may be the most important and sensitive visual cue. Visual range is not often useful for judging the effects of small changes in extinction. For example, a change in visual range from 50 to 60 km will not be noticed if the most distant landscape feature is at 25 km. The effect of haze on contrast is a better candidate as an indicator of change in haze; however, perceived contrast, like perceived hue, is affected in a nonlinear fashion by the semitransparent nature of haze and is not a sensitive indicator of changes in atmospheric haze.¹⁶ Experimental data have shown that colorfulness is a sensitive measure of changes in haze, so this article has used it to define just-noticeable changes in atmospheric haze.

A just-noticeable decrease in atmospheric haze is defined as a decrease in extinction that would produce a 95% probability of a measurable increase in colorfulness of an object seen through the haze. From the experimental evidence from the two young male observers, a JND in colorfulness was 4.8. For the population in general, this number is certainly too low, since all visual functions decline with age. Thus, the conclusions below about the deciview scale based on this number are understated for the general population.

Analysis of the experimental data showed that for a JND in atmospheric haze as defined above:

- (1) The deciview scale is not uniform in perception over a wide range of visibility conditions. In fact, the change in deciviews needed to be noticeable

varies greatly depending on the optical distance of the landscape feature and its inherent colorfulness.

(2) A 1-deciview change is never noticeable.

What are the implications of these results for measuring progress toward reducing regional haze using the deciview metric? This is difficult to judge because the current proposals are very complex, using particulate measurements and relative humidity to estimate the extinction coefficient and average deciviews for the 20% most-impaired and 20% least-impaired days. The goal is to show no change on the least-impaired days and improvement on the most-impaired days, leading to natural conditions by 2064.¹⁷

The results of this article highlight a possible flaw in this regulatory scheme based on the deciview metric. An unstated assumption is that the nature of the scenic vista can be ignored—that is, a given deciview change will affect the perception of all landscape features in all scenes in the same way. Figure 2 shows that this is approximately true only if all the important landscape features have nearly the same inherent colorfulness and are at distances that correspond to an optical depth of between 1 and 2, or about one quarter to one half of the visual range. In this limited case, the deciview is indeed a uniform metric. However, most scenic vistas do not fit these restrictions and, by Figure 2, will require greater decreases in extinction as measured by deciviews to show a perceptible change. The result is that the emission reductions required by the proposed regulatory analysis are likely to produce much smaller improvements in perceived effects of regional haze than expected. The EPA guidance documents provide an example of an eastern scenic vista with a baseline of 27 deciviews and natural conditions of 11.¹⁷ The decrease in extinction to reach natural conditions by 2064 is 0.35 deciview/yr, or 1.75 deciviews in five years. This five-year reduction should, according to the regulations, result in a noticeable change in regional haze. However, the results herein predict that there would very likely be no noticeable difference in any actual scenic vista in the region as a result of the required emission reductions.

Regional haze rules also call for a uniform rate of improvement in visibility (measured in deciviews) that is needed to go from current conditions to natural conditions by 2064. Since the deciview scale is not uniform in perception over a wide range of visibility conditions, this requirement is also flawed and will not result in uniform improvement in perceived visibility.

ACKNOWLEDGMENTS

The funding for this project was provided by the Electric Power Research Institute under Contract EP-P5419/C2683. The author would like to thank Dr. Naresh Kumar for his support and discussions leading to this work, and Drs.

Shudeish Mahadev and Santiago Urquito for their careful and diligent work as the observers in the field study.

Consideration of Low-Sulfur Coal in a BART Five-Factor Analysis for the White Bluff Power Plant

Prepared by Jackson Walker L.L.P. & Dover Dixon Horne PLLC

September 14, 2017

This document outlines legal and record-based arguments for the consideration of low-sulfur coal as a means to comply with Best Available Retrofit Technology (“BART”) requirements for the White Bluff Power Plant in Arkansas, which is made up of two coal-fired boilers – SN-01 and SN-02 (also referred to as Unit 1 and Unit 2), as well as one oil-fired auxiliary boiler – SN-05.¹ It is also intended to assist in establishing positive precedent for treating low-sulfur coal as a means of BART compliance.

A few initial guiding principles and limitations drive this analysis. First, it is important to note that care should be taken to ensure that the use of low-sulfur coal to comply with BART remain as a compliance *option*, not as a forced requirement. Forced fuel switching, particularly in the context of Best Available Control Technology (“BACT”) analysis for Prevention of Significant Deterioration (“PSD”) permitting, and attempts to “redefine the source” have been a consistent and lasting problem for electric generators (and other emission sources). Second, this analysis is a legal and record-based analysis; it does not incorporate new modeling or other technical arguments that could potentially facilitate the arguments outlined below.

Background

There are five statutory factors to be considered in applying BART. These are: 1) costs of compliance; 2) the energy and nonair quality environmental impacts of compliance; 3) any existing pollution control technology in use at the source; 4) the remaining useful life of the source; and 5) the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.² In applying these factors, EPA’s BART Guidelines³ outline five steps for conduct a case-by-case BART analysis. These are: 1) identifying all available retrofit control techniques (including existing controls); 2) eliminating technically infeasible control techniques; 3) evaluating control effectiveness of remaining control techniques; 4) evaluating impacts of the control techniques (including four subparts - cost, energy impacts, non-air quality environmental impacts, and remaining useful life); and 5) determining visibility impacts in the BART determination.⁴

Entergy in 2013 prepared a five-factor analysis for White Bluff as part of this docket.⁵ Entergy did not include low-sulfur coal as a potential compliance technique/technology. In 2015 (revised in 2016), Entergy prepared a five-factor analysis for the coal-burning Nelson Power Plant in Louisiana as part of that state implementation plan (“SIP”)/federal implementation plan (“FIP”) process.⁶ The ultimate

¹ This memorandum focuses solely on the two coal-fired boilers.

⁵ See Trinity Consultants, Revised BART Five Factor Analysis White Bluff Steam Electric Station Redfield, Arkansas (AFIN 35-00110), October 2013. (“2013 Entergy White Bluff Five-Factor Analysis”).

⁶ Trinity Consultants, BART Five Factor Analysis Produced in Response to Section 114 Request, Nov. 9, 2015; Revised April 15, 2016. (“Entergy Nelson Five-Factor Analysis”).

conclusion of the Nelson Five-Factor Analysis was that low-sulfur coal would serve as the BART compliant control and that no additional control technologies would be required. The Nelson Five-Factor Analysis, and the low-sulfur coal conclusion, was the basis for the Louisiana Department of Environmental Quality (“LDEQ”) revised SIP BART submissions in February and June 2017.⁷ It is also the basis of EPA’s *proposed* acceptance of the LDEQ’s SIP submission.⁸ Entergy also has recently submitted an updated five-factor analysis for White Bluff to the Arkansas Department of Environmental Quality that concludes that low-sulfur coal constitutes BART.⁹ However, neither Entergy’s 2013 five-factor analysis nor its 2017 five-factor analysis for White Bluff evaluate low-sulfur coal as an existing pollution control technology. This analysis, as well as previous comments and Petitions for Reconsideration, will serve as the basis for the following discussion.

White Bluff Five-Factor Analysis and Application of the Top-Down Case-by-Case BART Analysis

While there can be some discussion or debate regarding the use of EPA’s top-down approval to conducting a case-by-case BART analysis, including that states have greater flexibility in determining a BART-analysis approach, for the purposes of this memorandum, EPA’s approach is used.

1. Identifying All Available Retrofit Control Techniques

White Bluff currently uses low-sulfur coal, as dictated by its Arkansas Public Service Commission approval.¹⁰ Use of low-sulfur coal with approximately 0.5% sulfur content as a control for SO₂ emissions was approved for White Bluff (as well as at other coal-fired power plants in Arkansas) pursuant to the Arkansas Utility Facility Environmental and Economic Protection Act, Ark. Code Ann. §23-18-501, et seq. As a result, White Bluff has been operating since its inception using low-sulfur coal as a control technology for SO₂ emissions. While not a retrofit control, it is an existing control which EPA has recognized can (and should) be considered at this stage of the process.¹¹ As referenced above, it is also a recognized control (and ultimately selected control) in Louisiana’s SIP submission for the Nelson Plant and EPA’s proposed approval. Specifically, EPA’s Technical Support Document for its proposed approval stated:

“Switching to a lower sulfur coal is a feasible method for lowering SO₂ emissions. In fact, Entergy has been purchasing lower sulfur coals and blending them in its feed stream for a number of years.”¹²

As clearly articulated by the Eighth Circuit in *North Dakota v. EPA*, EPA is obligated to consider all control technologies used at the plant, voluntarily or otherwise.¹³ Low-sulfur coal is one of those controls.

¹³ See *North Dakota v. EPA*, 730 F.3d 750, 764 (8th Cir. 2013), which includes:

This memorandum does not opine on the “availability” of the other control technologies identified in Entergy’s White Bluff Five-Factor Analyses, which include dry sorbent injection (“DSI”), semi-dry scrubbing, and wet scrubbing.¹⁴

2. Eliminating Technically Infeasible Control Techniques

This memorandum does not address technical issues; therefore, the technical feasibility step is not addressed, but it is assumed that all controls deemed technically feasible in the Arkansas BART FIP are feasible.

3. Evaluating Control Effectiveness Of Remaining Control Techniques

Nucor’s comments filed in the FIP rulemaking docket sufficiently summarize the effectiveness of using low-sulfur coal, including:

“Entergy’s five-factor analysis points out that the amount of sulfur in coal is the most important factor in controlling SO₂ emissions. EPA’s own documents in support of the national Regional Haze Rule indicate that use of 0.7% low-sulfur coal reduces SO₂ emissions by over 70%. The U.S. Energy Information Administration states that low-sulfur coal may reduce SO₂ emissions by up to 85%. EPA has approved the use of low-sulfur coal as Best Available Control Technology for purposes of its PSD regulations. In fact EPA has approved the use of low-sulfur coal as BART for a coal-fired power plant even though it determined that Dry Sorbent Injection (‘DSI’) at a cost of only \$991/ton SO₂ was ‘cost-effective’ for that plant.”¹⁵

In EPA’s TSD for the Proposed Nelson SIP Approval, EPA found that switching to low-sulfur fuel would allow the Nelson unit to comply with an SO₂ emission limit of 0.60 lb SO₂/MMBtu (on a 30-day rolling average); this is the emission limit ultimately memorialized in EPA’s Proposal.¹⁶ In comparison, the White Bluff power plant (which has a permitted emission allowance of 1.2 lb SO₂/MMBtu) has been able to achieve monthly average emission rates in the range of 0.46 - 0.69 lb SO₂/MMBtu at the

“Because we find no ambiguity in the kind of technologies that must be considered under § 7491(g)(2), EPA’s interpretation that it was not required to consider the existing pollution control technologies in use at the Coal Creek Station is entitled to no deference. Just as the State was required to properly consider each statutory factor in the BART analysis in the implementation of its SIP, so too was EPA in the promulgation of its FIP. Accordingly, EPA’s refusal to consider the existing pollution control technology in use at the Coal Creek Station because it had been voluntarily installed was arbitrary and capricious and its FIP promulgating SNCR as BART for the Coal Creek Station is therefore vacated.”

¹⁵ Comments of Nucor-Steel-Arkansas and Nucor-Yamato Steel Company on Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Proposed Rule, Doc. No. EPA-R06-OAR-2015-0189-0163, July 15, 2015 at 29-30, citing to: 2013 Entergy White Bluff Five-Factor Analysis at 5.-1; Hawes, T., Worksheet from EPA’s docket EPA-HQ-OAR-2002-0076, document number 145 (included as Exhibit 13 of Nucor’s comment); EIA December 21, 2001 forecast (included as Exhibit 14 of Nucor’s comment); EPA’s Final BART determination for PPL Corrette, 77 Fed.Reg. 23988, 24031 (April 29, 2012) which approved the use of coal with a 0.3% sulfur content as BART.

¹⁶ EPA Nelson Rule Proposal at 32,300.

units.¹⁷ The average monthly emission rate between 2009 and 2015 was 0.56 lb SO₂/MMBtu for Unit 1 and 0.58 lb SO₂/MMBtu for Unit 2.¹⁸

As discussed above, EPA has determined that the use of low-sulfur coal by EGUs is the most important factor and reduces SO₂ emissions by at least 70% and the Energy Information Administration has determined that use of low sulfur coal by EGUs reduces SO₂ emissions by up to 85%. Thus, White Bluff is already achieving control of its SO₂ emissions by between 70-85%. So far in 2017, the sulfur content of White Bluff's coal supply is below 0.25%.¹⁹ Entergy's most recent five-factor analysis indicates that a 0.6 lb. SO₂/MMBtu emission rate would result in an additional 8% reduction in SO₂ emissions. Thus, continued use of low sulfur coal at that emission rate would result in emissions control of up to 93%.²⁰

EPA's BART Guidelines provide that when existing control measures are already in place "it is important to involve improvements to existing controls, and not limit the control options only to those measures that involve a complete replacement of control devices."²¹ In addition, the BART Guidelines state that if existing post-combustion controls achieve removal efficiencies of at least 50%, upgrades to improve efficiency should be considered instead of replacement.²² Here, White Bluff has used low-sulfur coal as a control technology to achieve at least 70% reduction of SO₂ emissions for over 35 years. By analogy, it is reasonable to consider improving emission reductions through use of a lower sulfur coal, in contrast to replacement with FGD. In addition, as discussed below, both state and federal environmental policy favor use of a pollution prevention control, such as low-sulfur coal, over use of a removal technology such as FGD.

Clearly, the control effectiveness demonstrated at the White Bluff unit via the use of existing controls, including the use of low-sulfur control, generates emissions that are in-line – and for a great period of time – below the emission limit EPA has proposed to accept in Louisiana (and which was at the core of Entergy's Nelson Five-Factor Analysis). Low-sulfur control is an effective control.

4. Evaluating Impacts of the Control Techniques

a. Cost

EPA estimates that costs of the dry flue gas desulfurization ("FGD") technology at the White Bluff Units 1 and 2 are projected by EPA to cost \$2,565/SO₂ ton and \$2,421/SO₂ ton.²³ Other analysis finds that the actual cost-effectiveness for scrubbers would be between \$5,462-\$6,445 more expensive per ton of SO₂ reduced than EPA's estimate in the FIP.²⁴ However, neither of these cost analyses consider the cost of the historic and continued cost use of low-sulfur coal at White Bluff. The installation of

¹⁷ See Arkansas Department of Environmental Quality, Petition for Reconsideration and Request for Administrative Stay, In re: Promulgation of Air Quality Implementation Plan; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule (Nov. 22, 2016), Appendix C, ("ADEQ Petition for Reconsideration")

¹⁸ *Id.*

¹⁹ U.S. Department of Energy, Energy Information Administration, EIA Form 923.

²⁰ This is only slightly less than the 95% control level used by EPA in establishing presumptive SO₂ emission limits in App. Y.

²¹ Appendix Y, section D.6, 70 F.R. 39,164.

²² Appendix Y, Section E.4, 70 F.R. 39,171.

²³ U.S. EPA, Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule, 81 Fed. Reg. 66,332, 66,343 (Sept. 27, 2016).

²⁴ ADEQ Petition for Reconsideration, Appendix C, citing to: Review of EPA's Cost Analysis for Arkansas Regional Haze Proposed Federal Implementation Plan (2015). Prepared by Sargent & Lundy for Entergy Arkansas, Inc., Docket No. EPA-R06-OAR-2015-0189.

FGD requires the continued use of low-sulfur coal, and thus the costs of low-sulfur coal must be included in the analysis of such additional control technology. Such costs would include the differences in heat content and transportation costs for low-sulfur coal over other grades of coal, which are substantial. Entergy's most recent five-factor analysis appears only to consider the incremental price difference between 0.5% low-sulfur coal and a lower sulfur content grade of coal. Furthermore, when the historic costs of use of low-sulfur coal are included in the cost-effectiveness analysis of FGD, the costs far exceed the range of cost-effectiveness for EPA's presumptive SO₂ emissions.²⁵

Acknowledging that there are uncertainties that are not addressed in this memorandum, since White Bluff already utilizes low-sulfur coal in its operations, presumably there would be no additional costs for the continued use of low-sulfur coal and if there are any additional costs, these costs would be far less than the costs of the installation of the various control technologies discussed in the FIP (and ultimately selected for White Bluff).²⁶ Therefore, the continued use of low-sulfur coal as a control technology provides lower additional capital and operating costs (or create no additional costs all all), while still achieving emission reductions.

Further, in the proposed Nelson SIP approval, EPA has already proposed to recognize that "lower-sulfur coal still achieves some visibility benefits and at a lower annual cost" than installing dry FGD at the Nelson power plant.²⁷ Importantly, in that case, Entergy would be required to switch to low-sulfur coal (which creates costs); these costs would not be incurred at the White Bluff power plant, further increasing the cost savings of using low-sulfur coal.

b. Energy Impacts

The continued use of low-sulfur coal as BART at the White Bluff power plant avoids the additional energy impacts associated with control technologies, such as dry FGD scrubbers. Namely, technological controls require electricity to operate, generating parasitic load issue or require auxiliary power.²⁸ These parasitic loads and auxiliary power demands are not required if low-sulfur coal is continued to be used at the White Bluff power plant. Furthermore, the additional extensive costs associated with installation of FGD at White Bluff could lead to premature closure or retirement, which could affect the reliability and resiliency of the electric grid and electric supply in Arkansas, and lessen or eliminate the use of low-sulfur coal as a hedge against other fuels for generation of electricity for Arkansas utility customers.

c. Non-Air Quality Environmental Impacts

The continued use of low-sulfur coal at White Bluff power plant as a means of compliance creates no additional non-air quality environmental impacts.²⁹ In contrast, the use of FGD can create additional

²⁵ While EPA's adherence to use of its Cost Control Manual may have some utility for comparing the cost-effectiveness of various proposed control technologies, it does not address the ultimate cost of controls. The Cost Control Manual does not consider all costs associated with the installation of FGD at White Bluff, such as AFUDC. This is a real, absolute cost which must be taken into account to arrive at a proper BART determination, and it would be unreasonable not to do so. See *Michigan v. EPA*.

²⁶ In the Nelson BART analysis docket, Entergy represented that switching to low sulfur coal created a \$0.50/ton premium, resulting in a cost effectiveness of \$597/ton. See TSD for the Proposed Nelson SIP Approval at 42.

²⁷ See EPA Nelson Rule Proposal at 32,300.

²⁸ See TSD for the Proposed Nelson SIP Approval at 45.

²⁹ See TSD for the Proposed Nelson SIP Approval at 46, which found that "There are no non-air quality environmental impacts associated with switching to a lower sulfur coal."

waste due to spent reagent and has some power impacts.³⁰ Further, the White Bluff plant has been operating at lower load than it is operationally able to achieve. Additional power demands (i.e. parasitic load) of scrubbers may result in additional power generation (to offset these demands), additional waste or emissions than what would be expected without the additional control, and other associated impacts.

The Arkansas Pollution Prevention Act, Arkansas Code Ann. §8-10-201 et seq. establishes a hierarchy of waste minimization that favors pollution prevention at the source over reuse, recycling, treatment and disposal. The federal Pollution Prevention Act, 42 U.S.C. 13101, et seq. establishes as the national policy of the United States “that pollution should be prevented or reduced at the source whenever feasible.” 42 U.S.C. 13101(b). Reduction of SO₂ emissions from improved use of low-sulfur coal furthers both state and national policy by reducing pollution at the source. Installation of FGD creates a new waste stream that must be treated and disposed of, contrary to the Arkansas and federal policy. In light of this long stated state and federal policy favoring source reduction, the minimal visibility benefits that will be achieved, if any, do not weigh in favor of use of FGD; instead, the weight is in favor of increased efficiency of the use of low-sulfur coal.

d. Remaining Useful Life

There are no remaining useful life concerns or considerations with the continued use of low-sulfur coal. In contrast, requiring the installation of any control technology – particularly a control as capital intensive as a dry FGD – requires expenditures that would have to be amortized over a long period of time, that could be constrained if the useful life of the plant is unexpectedly shortened. If debt is assumed, then it may also create concerns regarding paying off these debts during the remaining useful life of the plant, if a determination is made to retire the plant earlier than expected. Furthermore, because public utility assets, such as White Bluff, are held in trust for the benefit of the public, installation of expensive controls such as FGD would require consideration of other important factors that are not implicated by continued use of low-sulfur coal.

5. Determining Visibility Impacts In the BART Determination

White Bluff currently uses low-sulfur coal. Therefore, the visibility benefits of using low-sulfur coal are already being realized. The BART statute, guidelines, case law,³¹ and other state rule proposals³² clearly allow for the consideration of existing use of low-sulfur coal in the BART analysis, and consideration of the positive visibility impacts that have been achieved via this controls. Further, these are visibility benefits that will be enjoyed for the next five years (until the October 21, 2021 compliance date established in the FIP).

EPA has admitted that due to its inherent limitations and uncertainty, CALPUFF is not useful to determine absolute visibility impacts, but only to compare the visibility impacts of different control technologies. In its response to comments on its Regional Haze Rule Federal Implementation Plan, EPA stated:

³⁰ See EPA Nelson Rule Proposal at 32,300.

³¹ See *North Dakota v. EPA* at 764.

³² See EPA Nelson Rule Proposal at 32,300, which states that “The LDEQ acknowledged that the visibility benefits of SDA and wet FGD are larger than those associated with lower-sulfur coal, but explained that lower-sulfur coal still achieves some visibility benefits and at a lower annual cost.”

While there is some uncertainty in the *absolute visibility impacts* and benefits due to the model and some of the simplifications and assumptions used in the BART guideline modeling approach, the relative level of impact is a reliable assessment of the degree of visibility impacts and benefit from the controls. Any uncertainties in meteorological conditions that govern the transport and diffusion of pollutants are less important *in comparing impacts between two control scenarios*, since the same effects will be included in both the base and the control scenario model simulations. CALPUFF modeling will be better at predicting changes in visibility impairment due to the application of controls than at predicting the absolute visibility impacts . . . The modeled magnitude of the visibility improvement is not a determinative factor in the BART determination, but only one factor and is considered on a relative basis to the baseline impact and the benefits of other controls.³³

Consequently, EPA has admitted that CALPUFF cannot support the absolute visibility impacts predicted by EPA and Entergy, especially at the distances involved for White Bluff. This is due to conditions that are not well accounted for in the CALPUFF model, but which nevertheless are present at the distances involved with White Bluff.³⁴ Even though CALPUFF may be able to distinguish visibility impacts of various control technologies, due to its limitations CALPUFF does not establish the absolute visibility impact of a particular control technology. Because deciview differences contained in the White Bluff five factor analyses are derived from the modeled absolute visibility impacts, these limitations inherent in the CALPUFF model also logically affect the differences shown in the modeled visibility impacts between two control technologies. Even with these admitted limitations, the modeled improvements in the White Bluff five factor analyses are still below the amount that is perceptible to humans and well below the 2-3 dv accuracy and precision of the CALPUFF model that EPA admits.³⁵

Due to the fact that CALPUFF is not a reliable method for determining BART under the circumstances involving White Bluff, ADEQ may look to other evidence. CENRAP modeling shows that *all* Arkansas point sources together in 2002 contributed less than 3.5% of sulfate light extinction at Arkansas Class I areas.³⁶ Given that White Bluff contributes only a fraction of statewide point source SO₂ emissions, it is likely that further reduction of SO₂ emissions from installation of FGD would reduce light extinction from sulfates at the Class I areas by substantially less than that.³⁷

In addition, the historic and continued use of low sulfur coal at White Bluff (and other Arkansas coal-fired power plants) has been sufficient to meet reasonable progress visibility requirements, as Arkansas is already at or below the regional haze glide path. 2015 monitoring data demonstrates that Arkansas is currently meeting the reasonable progress goals set in the FIP and will continue to meet those goals throughout 2018 – the first planning period.³⁸ Further, the most recent monitoring

I. Introduction

On October 31, 2017, the Arkansas Department of Environmental Quality (“ADEQ”) released for public review draft revisions to certain disapproved portions of the 2008 Arkansas Regional Haze State Implementation Plan (“SIP”) (“Draft SIP”). The Draft SIP addresses certain best available retrofit technology (“BART”) and reasonable progress controls for sources in Arkansas for the first planning period.¹ EPA’s approval of the Draft SIP would result in the withdrawal of the applicable BART and reasonable progress requirements in the Arkansas Regional Haze Federal Implementation Plan (“Final FIP”) that EPA promulgated in 2016 to address the disapproved portions of Arkansas’ regional haze plan. 81 Fed. Reg. 66,332 (Sept. 27, 2016). On December 19, 2017, ADEQ extended the public comment period on the Draft SIP to January 19, 2018, and subsequently, on January 12, 2018, ADEQ further extended the public comment period to February 2, 2018.

Entergy Arkansas, Inc. (“EAI” or “Entergy”) is an electric utility engaged primarily in the generation, purchase, transmission, distribution, and sale of electricity in portions of Arkansas. EAI provides electrical utility service to approximately 707,000 electric customers. EAI owns and operates three facilities directly impacted by the Draft SIP: the White Bluff Electric Power Plant (“White Bluff”), the Independence Steam Electric Station (“Independence”), and the Lake Catherine Plant (“Lake Catherine”).

¹ On July 8, 2017, ADEQ proposed revisions to the State’s Regional Haze SIP to address emissions of nitrogen oxides (“NOx”) from electric generating units (“EGUs”) for BART and reasonable progress purposes (“Phase I SIP”). Entergy submitted comments to ADEQ on the Phase I SIP on August 14, 2017. On January 24, 2018, EPA issued its final approval of the Phase I SIP. Approval and Promulgation of Implementation Plans; Arkansas; Approval of Regional Haze State Implementation Plan Revision for NOx for Electric Generating Units in Arkansas (prepublication version) (Jan. 24, 2018) (“Phase I SIP Approval”). Other BART requirements were previously approved by EPA in Arkansas’ regional haze plan. 77 Fed. Reg. 14,604 (Mar. 12, 2012).

Entergy largely agrees with ADEQ's proposed BART determinations, but urges ADEQ to revise its analyses and support for these determinations to account for all relevant information. Specifically, Entergy supports ADEQ's proposed BART sulfur dioxide ("SO₂") limits for White Bluff's two coal-fired electric generating units (Units 1 and 2), but urges ADEQ to revise its analysis supporting these limits to consider the date by which Entergy expects the plant will cease to use coal.²

Entergy disagrees with ADEQ's proposed determination that a reasonable progress analysis for SO₂ is required for Independence in light of the state's attainment of the reasonable progress goals for Arkansas' Class I areas during the first planning period. In the event that ADEQ proceeds with a reasonable progress analysis, ADEQ should broadly consider all relevant factors impacting the appropriateness of controls, as well as revise its consideration of the four statutory reasonable progress factors. *See* 42 U.S.C. § 7491(g)(1). Entergy also urges ADEQ to consider planned reductions at White Bluff, Lake Catherine, and Independence as part of its Long-Term Strategy ("LTS").

Finally, Entergy agrees with ADEQ that no changes to the particulate matter ("PM") BART limits are required for White Bluff or Lake Catherine, or to the SO₂ BART limit for Lake Catherine, but urges ADEQ to eliminate these limits from the Draft SIP and the draft Administrative Order ("AO").³ These limits already have been approved by EPA, are included in the plants' Title V permits and are in effect. Attempting to reissue them in the Draft SIP and make them enforceable through the AO is unnecessary and confusing.

² Entergy is prepared to take an enforceable restriction to this effect.

³ While these comments suggest some changes to the AO, Entergy anticipates that it will continue working with ADEQ to further refine the AO before finalization, as is customary for negotiated orders under the Arkansas Water and Air Pollution Control Act, § 82-1901 et seq.

II. Comments

A. ADEQ Should Finalize the Proposed White Bluff SO₂ BART Determination but Revise the BART Analysis

The Draft SIP would establish SO₂ BART emission rates for White Bluff Units 1 and 2⁴ of 0.6 lb/MMBtu, calculated as a 30-day rolling average over each boiler operating day, based on the use of low sulfur coal (“LSC”).⁵ Draft SIP at 25. Entergy supports this determination but urges ADEQ to revise its BART analysis to reflect the company’s expectation that it will cease combusting coal at White Bluff on or before December 31, 2028.

1. *ADEQ should recognize White Bluff’s expected cease-to-use-coal date when assessing Remaining Useful Life.*

In assessing Entergy’s most recent BART five-factor analysis for SO₂ controls at White Bluff,⁶ ADEQ “agrees that Entergy’s cost-effectiveness calculations are reasonable based on a remaining useful life of seven years and Entergy’s proposal to take an enforceable limit regarding the timing of their planned changes in coal-fired operations date.” *See* Draft SIP at 24. While Entergy’s BART five-factor analysis does employ a seven-year amortization period for the cost of Dry Flue Gas Desulfurization (“FGD”), this amortization period is based on a cease-to-use-coal date of 2028.⁷ Updated Five-Factor Analysis at 4-4. ADEQ adopts the seven-year amortization

⁴ ADEQ should correct its description of White Bluff’s history. The White Bluff units were not “installed in 1974” as stated in the Proposed SIP. Draft SIP at 28. Construction commenced on the White Bluff units in 1974. Commercial operation began in 1980 for Unit 1 and 1981 for Unit 2.

⁵ As explained in Section F, *infra*, LSC is not an “existing control” at White Bluff or Independence.

⁶ White Bluff Steam Electric Station, Updated BART Five-Factor Analysis for SO₂ for Units 1 and 2 (Aug. 18, 2017) (“Updated Five-Factor Analysis”). Entergy submitted the Updated Five-Factor Analysis to ADEQ on August 18, 2017, with certain information redacted as confidential business information, but released the confidential business information in a letter to ADEQ dated December 1, 2017. *See* Letter from John F. Peiserich, PPGMR Law, PLLC, to Stuart Spencer, ADEQ (Dec. 1, 2017). An unredacted version of the Updated Five-Factor Analysis is attached to these comments as Exhibit E.

⁷ Entergy employed a nine-year amortization period for Dry Sorbent Injection (“DSI”) and Enhanced DSI. Updated Five-Factor Analysis at 4-4.

period for its analysis of Dry FGD,⁸ but assumes that White Bluff will cease to use coal in 2030, rather than 2028. ADEQ calculated the seven-year amortization period based on a compliance date five years after EPA approval of the SIP. Draft SIP at 24, n.21. Assuming the replacement SIP is finalized and approved by EPA in 2018, ADEQ calculated that the compliance date for SO₂ limitations based on the projection that Dry FGD would be installed in 2023. ADEQ then assumed that Entergy's seven-year amortization period would result in a cease-to-use-coal date of 2030. The assumption that White Bluff will cease combusting coal in 2030 has no basis in the record, likely is factually inaccurate and does not reflect the information that Entergy submitted to ADEQ. ADEQ should revise the SIP to reflect Entergy's expectation that it will cease using coal at White Bluff by the end of 2028.⁹

Remaining useful life is a factor that the state must take into account: "in determining [BART] the State ... *shall* take into consideration ... the remaining useful life of the source" CAA § 169A(g)(2) (emphasis added); 40 C.F.R. § 51.308(e)(1)(ii)(A) (in determining BART, "the State *must* take into consideration ... the remaining useful life of the source...") (emphasis added). As ADEQ recognizes, the BART Guidelines plainly state that a BART determination should consider the remaining useful life of the facility. Draft SIP at 24 (citing Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations, 70 Fed. Reg. 39,104, (July 6, 2005)). Remaining useful life is critical for calculating the cost-effectiveness of control options, as the costs of controls are amortized over the expected remaining life of the unit. Entergy's Updated BART Five-Factor Analysis explicitly established the date by which EAI expects to cease burning coal at the White Bluff units, stating that Entergy "anticipates Unit 1 and

⁸ Like Entergy, ADEQ used a nine-year amortization period for DSI and Enhanced DSI. *See* Draft SIP at 23.

⁹ All references to the expectation that coal combustion will cease in 2028 refer to the end of 2028.

Unit 2 will cease to use coal by the end of year 2028, and, upon acceptance of the BART determinations contained herein in an approved SIP, is prepared to take an enforceable restriction to this effect.” Updated Five-Factor Analysis, at 4-4.

This date is consistent with Entergy’s previous analyses for White Bluff and its publicly stated expectation that it will cease using coal at both units by 2028. *See* EAI Comments on the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 2, 5, Docket No. EPA-R06-OAR-2015-0189-0166 (Aug. 7, 2015) (“EAI Arkansas FIP Comments”) (proposing “to cease all coal-fired operations at the two coal-fired units [at White Bluff] in 2027 and 2028” and to take an “enforceable commitment to that effect.”)) (attached as Exhibit A, attachments omitted); *see* Petition for Reconsideration and Request for Stay of Entergy Arkansas Inc., et al., at 5, Docket No. EPA-R06-OAR-2015-0189-0243 (Nov. 23, 2016) (“Entergy Petition for Reconsideration”) (criticizing the Final FIP for “fail[ing] to consider Entergy’s proposal to cease combusting coal in 2027 and 2028, which would limit the remaining useful coal-fired lives of the units and significantly alter the cost-effectiveness of SO₂ controls.”) (attached as Exhibit B, attachments omitted).

It is unclear why ADEQ did not use this information when assessing the remaining useful life of the units. Entergy had made public its expectation that it would cease to use coal at White Bluff by 2028, and provided ADEQ with an Updated Five-Factor Analysis indicating that all coal use would cease by 2028. Despite this, the Agency proposed a cease-to-use-coal date of 2030 in the draft AO to support the SIP, which directly conflicts with the information provided by EAI, the operator and a co-owner of the units. Neither the statute nor the regional haze regulations provide ADEQ with the authority to reassess and redefine the remaining useful life of a source.

EAI provided to ADEQ the specific date by which the White Bluff units are expected to cease to use coal, and ADEQ should take this date into account to strengthen its analysis and ensure that its final decision has a reasonable basis. Indeed, failure to consider this relevant information about the units' remaining useful life from the operator and co-owner is arbitrary. *See e.g., White Cty. Guar. Sav. & Loan Ass'n v. Farmers & Merchants Bank of Des Arc*, 262 Ark. 893, 900, 562 S.W.2d 582, 585 (1978) (an administrative action will be set aside as arbitrary and capricious when it is a “willful and unreasoning action,’ without consideration and in disregard of the facts or circumstances of the case.”) (quoting *First National Bank of Fayetteville v. Smith*, 508 F.2d 1371, 1376 (8th Cir. 1974)). *See also McQuay v. Arkansas State Bd. of Architects*, 337 Ark. 339, 347-48 (1999) (finding a state board's assessment of penalties to be arbitrary and capricious due to the board's failure to account for the date on which the violations ended).

Accordingly, ADEQ should revise its BART analysis for White Bluff Units 1 and 2 to take into account the cease-to-use coal date of 2028 that Entergy provided in the Updated Five-Factor Analysis. This would result in a five-year amortization period for the installation of Dry FGD,¹⁰ and would strengthen ADEQ's determination that Dry FGD should not be considered BART for White Bluff.

2. *In light of the limited remaining useful life, LSC is BART for White Bluff.*

ADEQ's BART analysis assesses four possible controls for White Bluff: DSI, enhanced DSI, Dry FGD,¹¹ and LSC. Entergy submitted a BART five-factor analysis for White Bluff that

¹⁰ It also would result in a seven-year amortization period for DSI and Enhanced DSI.

¹¹ ADEQ did not consider Wet FGD, noting that the difference in cost between Wet and Dry FGD is “marginal.” *See* Draft SIP at 22. (“This option was eliminated in previous analyses and in the AR RH FIP due to the small incremental difference in visibility improvement between Wet FGD and Dry FGD relative to the marginal cost difference”). EAI disagrees that the cost difference should be characterized as “marginal.” EPA estimated Dry FGD at a cost of \$2,565/ton of SO₂ removed for Unit 1 and \$2,421/ton of SO₂ removed for Unit 2, 81 Fed. Reg. at 66,386, and Wet FGD to have an average cost-effectiveness of \$3,152/ton of SO₂ removed for Unit 1 and \$3,092/ton of SO₂ removed for Unit 2, 80 Fed. Reg. 18, 944,

analyzed the same four potential controls. Based on its analysis, Entergy agrees with ADEQ that, in light of the limited remaining useful life, DSI and Dry FGD are not cost-effective at White Bluff, and that BART should be based on the use of LSC. However, ADEQ should revise its cost-effectiveness analysis in light of Entergy’s proposed remaining useful life for White Bluff and to correct certain other errors.

ADEQ calculated the average cost-effectiveness of DSI to be \$6,238 per ton for Unit 1 and \$6,211 per ton for Unit 2, and the average cost-effectiveness of “enhanced” DSI to be \$6,426 per ton for Unit 1 and \$6,384 per ton for Unit 2. White Bluff Cost Calculations Technical Support Document. It calculated the average cost-effectiveness of Dry FGD to be \$5,429 per ton for Unit 1 and \$5,387 for Unit 2. *Id.* See Table 1.

Table 1: ADEQ’s Cost-Effectiveness Calculations		
	Unit 1	Unit 2
DSI	\$6,238	\$6,211
Enhanced DSI	\$6,426	\$6,384
Dry FGD	\$5,429	\$5,387

These cost-effectiveness values exceed the amounts that EPA in the past has determined are not cost-effective.¹² For example, EPA declined to impose dry FGD as BART in Arizona,

18,972 (April 8, 2015). This is a difference of \$587/ton of SO₂ removed at Unit 1 and \$671/ton of SO₂ removed at Unit 2. EAI does not consider these differences to be marginal. However, EAI does agree that wet FGD is not a cost-effective control and should not be analyzed further.

¹² Entergy’s calculations of the costs of DSI, Enhanced DSI, and Dry FGD, assuming a nine-year remaining useful life for DSI and Enhanced DSI and a seven-year remaining useful life for Dry FGD, are *higher* than the costs calculated by ADEQ, making the control technologies even less cost-effective than ADEQ concluded. As described in its revised Five Factor Analysis for White Bluff, based on actual costs, Entergy calculated the average cost effectiveness of DSI to be \$7,081 -- \$7,148/ton, Enhanced DSI to be \$7,322 - - \$7,372/ton, and Dry FGD to be \$7,080 -- \$7,124/ton. Even accounting for EPA’s disallowed costs, the cost-effectiveness values for these controls are still too high to be considered BART: \$6,211 -- \$6,267/ton for DSI, \$6,384 -- \$6,427/ton for Enhanced DSI, and \$5,387 -- \$5,420/ton for Dry FGD. See Updated Five-Factor Analysis at 4-5.

where the average cost effectiveness was estimated to be \$5,091/ton. Proposed Arizona Regional Haze FIP, 79 Fed. Reg. 9,318, 9,331-33 (Feb. 18, 2014); Final Arizona Regional Haze FIP, 79 Fed. Reg. 52,420, 52,436 (Sept. 3, 2014). In North Dakota, EPA approved the state's determination that a cost effectiveness of \$6,525 per ton was excessive for NO_x controls and did not constitute BART. Proposed North Dakota FIP, 76 Fed. Reg. 58,570, 58,630 (Sept. 21, 2011); Final North Dakota Regional Haze FIP, 77 Fed. Reg. 20,894, 20,896 (Apr. 6, 2012). In Montana, EPA concluded that certain SO₂ controls with a cost effectiveness of \$5,442/ton and \$6,365/ton were not cost effective. Proposed Montana Regional Haze FIP, 77 Fed. Reg. 23,988, 24,047 (Apr. 20, 2012); Final Montana Regional Haze FIP; 77 Fed. Reg. 57,864, 57,866 (Sept. 18, 2012).

In comparison, ADEQ calculated LSC to cost approximately \$1,150 per ton of SO₂ reduced, Draft SIP at 23, which is cost-effective. However, ADEQ's determination that LSC is BART for the White Bluff units would be strengthened if it were based on EAI's anticipated cease-to-use coal date of 2028, since it would yield a five-year amortization period for the installation of Dry FGD at White Bluff, which would render Dry FGD at White Bluff even *more* uneconomic, at \$6,912 per ton for Unit 1 and \$6,869 for Unit 2.¹³

3. *The proposed three-year compliance period for SO₂ is appropriate.*

EAI supports ADEQ's proposal that White Bluff be allowed three years after EPA's approval of the SIP revision to meet the LSC BART limitation of a rolling 30-boiler operating day average SO₂ emission rate of 0.6 lb/mmBTU.¹⁴ See Draft SIP at 25. It is Entergy's practice to project how much coal will be needed in future years and to contract for a portion of the coal

¹³ DSI or Enhanced DSI at a seven-year amortization period would similarly be more uneconomic as BART than the costs that ADEQ calculated for these controls with a nine-year amortization period.

¹⁴ EAI similarly agrees with ADEQ that a five-year compliance period is appropriate for installation of control technology such as FGD.

supply up to three years in advance. Entergy also is required to keep a reserve supply of coals at White Bluff to ensure that the units can operate in the event of a fuel supply disruption. Accordingly, Entergy will need sufficient time to ensure that *all* its contracted coal supply meets the SO₂ BART emission rate, once finalized and approved by EPA. A three-year timeline is reasonable and complies with the Regional Haze Rule, which allows up to five years for compliance with BART. 40 C.F.R. § 51.308(e)(iv).

B. The Reasonable Progress Analysis Should Be Revised

EAI urges ADEQ to revise its reasonable progress analysis to ensure that the final SIP is legally durable and reflects the State's authority to implement the Regional Haze Program. For reasonable progress purposes, the Draft SIP would require Independence¹⁵ to meet a 30-boiler operating day rolling average SO₂ emissions limitation of 0.6 lb/MMBtu based on LSC. Draft SIP at 47. While Entergy agrees with ADEQ's determination that Dry FGD or another add-on control technology is not necessary at Independence to demonstrate that the state has made reasonable progress during the first planning period as would be required by the Final FIP, Entergy further believes that *no* assessment of reasonable progress is even required because Arkansas *already* is meeting its reasonable progress goals for the first planning period and the two Class I areas are below their glidepaths.

If ADEQ determines a reasonable progress analysis nonetheless is required, then it should be a broader analysis than the one ADEQ conducted, looking at more sources and at all relevant factors rather than a source-specific analysis focused solely on Independence. Nonetheless, in the event that the Final SIP includes a source-specific reasonable progress analysis for Independence,

¹⁵ ADEQ should revise its description of Independence's history. The Independence units were not "installed in 1983" as stated in the Draft SIP. Draft SIP at 42. Construction commenced on the Independence units in 1978. Commercial operation began in 1983 for Unit 1 and in 1984 for Unit 2.

ADEQ should correct flaws in its analysis and account for all relevant information, including the plant's anticipated cease-to-use-coal date. Revising the reasonable progress analysis consistent with Entergy's comments would result in a more robust and legally durable SIP while preserving the State's authority as the primary entity responsible for implementing the Regional Haze Program.

1. *Arkansas already is meeting its reasonable progress goals, so no reasonable progress analysis is required.*

The threshold issue when addressing reasonable progress is whether further actions are *necessary* to ensure that visibility improvement is continuing toward background levels (i.e., on or below the "glide path"). The Clean Air Act ("CAA") requires implementation plans to "contain such emission limits, schedules of compliance and other measures *as may be necessary* to make reasonable progress." See 42 U.S.C. § 7491(b)(2) (emphasis added). Consistent with this, EPA's Reasonable Progress Guidance¹⁶ makes clear that reasonable progress controls may not be necessary in the first planning period, noting that, "[g]iven the significant emissions reductions that we anticipate to result from BART" and other CAA programs "it may be all that is necessary to achieve reasonable progress in the first planning period."). Reasonable Progress Guidance at 4-1. See also, *id.* at 1-4 ("[Y]ou should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for you to defer reductions to later planning periods in order to maintain a consistent glidepath toward the longterm goal."). In sum, only if further action beyond BART and other CAA programs is *necessary* for reasonable progress may ADEQ require additional controls.

¹⁶ U.S. EPA, *Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program* (June 1, 2007) ("Reasonable Progress Guidance"). Available at https://www3.epa.gov/ttn/naaqs/aqmguides/collection/cp2/20070601_wehrum_reasonable_progress_goals_reghaze.pdf.

ADEQ has not made such a determination. Had it assessed whether controls beyond BART or other CAA programs are necessary to make reasonable progress for the first planning period, it would have concluded that they are not, and that no further analysis was required. Arkansas already has achieved visibility improvements in its Class I areas that surpass the Draft SIP's reasonable progress goals for the first planning period (*i.e.*, 22.51 dv for Upper Buffalo and 22.47 dv for Caney Creek, Draft SIP at 48, which were the same as the goals EPA set in the Arkansas FIP¹⁷), rendering the imposition of reasonable progress controls on Independence unnecessary for the first planning period.

ADEQ's analysis demonstrated that visibility in Caney Creek and Upper Buffalo was anticipated to meet the reasonable progress goals in the Draft SIP, even in the absence of controls on Independence. *See* Arkansas Department of Environmental Quality, *State Implementation Plan Review for the Five-Year Regional Haze Progress Report*, at 55-56 (May 2015). This is consistent with EPA's determination in its Proposed FIP that Arkansas' Class I areas were projected to meet the glidepath for the first planning period, even without controls on Independence, 80 Fed. Reg. at 18,992, effectively conceding that the controls are not "necessary" in the first planning period to ensure reasonable progress towards the natural visibility goal. *See* 42 U.S.C. § 7491(b)(2).¹⁸

¹⁷ EAI reserves the right to provide additional feedback on these goals in the future. It appears that ADEQ is relying on a methodology similar to that employed by EPA in the Arkansas FIP and as established by EPA in the Regional Haze Revision Rule, 82 Fed. Reg. 3,078, 3,089 (Jan. 10, 2017), both of which currently are the subject of legal challenge. *See* Draft SIP at 48. EAI disagreed with EPA's reasonable progress goals in the proposed Arkansas FIP, *see* EAI Arkansas FIP Comments at 49, and believes that its objections to EPA's methodology may be applicable here. Additional time to submit comments would allow EAI to more fully analyze ADEQ's methodology.

¹⁸ As stated below, although Entergy disagrees with ADEQ's proposed determination that LSC should be required for Independence as a reasonable progress control, Entergy would agree to take 30-boiler operating day rolling average SO₂ limits for Independence Units 1 and 2 of 0.6 lb/mmBTU.

These predictions have been confirmed by more recent IMPROVE data for 2016, which show that visibility measurements in both Caney Creek and Upper Buffalo were better than the reasonable progress goals in the FIP. Entergy's Updated Analysis of Reasonable Progress at 5-1 – 5-2 (Sept. 27, 2017) ("Analysis of Reasonable Progress"). These improvements are likely to be maintained in light of the planned compliance strategies to meet the BART requirements (e.g., the cessation of coal burning by 2028 and installation of low-NO_x burners at White Bluff as well as the BART requirements imposed on other sources) and implementation of other CAA programs such as the Cross State Air Pollution Rule ("CSAPR").

Visibility at Arkansas Class I areas is expected to further improve due to the imminent retirements of five power plants in neighboring states, including the Sandow Power Plant, Big Brown Power Plant, and Monticello Power Plant in Texas. These units, which total roughly 4,100 megawatts, are scheduled to be taken offline in early 2018.¹⁹ The Deely Plant in east Texas and the Allen Plant in Tennessee also are scheduled to retire in 2018. *See* Trinity Consultants, *Effects of Coal-Fired Power Plant Closures in First Planning Period on Visibility in Arkansas Class I Areas*, at 2-1 (Feb. 2, 2018) (attached as Exhibit C). The elimination of emissions from these five power plants during the first planning period are anticipated to help ensure that Caney Creek and Upper Buffalo remain below the glidepath through the end of the first planning period and into the second planning period. Specifically, these retirements will result in emissions reductions of greater than 206,000 tons per year of SO₂ and more than 39,000 tons per year of NO_x. *Id.* These reductions are significantly higher than the emissions reductions anticipated by the Final FIP, the

¹⁹ Press Release, Luminant, *Luminant Announces Decision to Retire its Monticello Power Plant* (Oct. 6, 2017), at <https://www.luminant.com/luminant-announces-decision-retire-monticello-power-plant/>; Press Release, Luminant, *Luminant to Close Two Texas Power Plants* (Oct. 13, 2017), at <https://www.luminant.com/luminant-close-two-texas-power-plants/>.

final Phase I SIP, and the Draft SIP. They also are greater than the maximum emissions from White Bluff and Independence combined. *Id.* at 2-1 – 2-2. As a result, the retirement of the four Texas plants is predicted to result in a total reduction of approximately 2.5 percent in visibility extinction at Caney Creek and about 0.8 percent at Upper Buffalo, based on EPA’s modeling for the Texas Reasonable Progress FIP.²⁰ *Id.* at 3-2. Figures 1 and 2 illustrate how these emission reductions are predicted to ensure that visibility impairment will remain well below the glidepath until the end of the second planning period. The additional reductions from the retirement of the Allen Plant will further contribute to visibility impairment remaining below the glidepath. *Id.*

Figure 1. CACR Glidepath with Observed and 2018 Predicted Haze Index

²⁰ 79 Fed. Reg. 74,818 (Dec. 16, 2014).

Figure 2. UPBU Glidepath with Observed and 2018 Predicted Haze Index

In addition to being legally unnecessary, ADEQ’s assessment of reasonable progress control options despite Arkansas’ substantial progress toward the national visibility goal conflicts with its own pending administrative petition for reconsideration and petition for judicial review of the Final FIP. In its administrative petition requesting that EPA reconsider the Final FIP, ADEQ urges EPA to “reconsider whether controls on Independence are necessary under the Clean Air Act because 2015 monitoring data shows that Arkansas is currently meeting the reasonable progress goals set in the FIP and will continue to meet those goals for the remainder of the first planning period.” Administrative Petition for Reconsideration and Request for Stay of ADEQ at 3 (Nov. 23, 2016). Similarly, in its opening brief in the litigation challenging the Final FIP, ADEQ argues that “[t]he Final [FIP] should be vacated because EPA ignored evidence that Arkansas would achieve reasonable progress—and natural visibility before 2064—without any additional controls.” Opening Br. for Arkansas at 36, *Arkansas v. EPA*, No. 16-4270 (8th Cir. Feb. 17, 2017). ADEQ’s determination is inconsistent with its interpretation of the reasonable progress

requirements of the CAA. ADEQ is challenging EPA for having made a similar determination regarding the need for reasonable progress controls in the Final FIP.

ADEQ's current approach also may limit its ability to change course in the second and subsequent planning periods. An EPA approval of ADEQ's decision to perform an unnecessary reasonable progress analysis may limit ADEQ's discretion in deciding against performing a reasonable progress analysis under similar conditions in the future. ADEQ might be forced to assess reasonable progress controls even if visibility improvement exceeds the goals, increasing the likelihood that unnecessary controls would be imposed upon Arkansas point sources.

In light of the foregoing, ADEQ should revise the SIP to conclude that no controls are necessary for Independence given the attainment of the reasonable progress goals at Arkansas's Class I areas. Based on the most recent air quality monitoring data, no further measures are *necessary* for Arkansas to make reasonable progress toward the Regional Haze Program's visibility goal in the first planning period, so a reasonable progress analysis is not required. Such a determination would be consistent with EPA's instruction that reductions may be deferred "to later planning periods in order to maintain a consistent glidepath toward the longterm goal."²¹

Reasonable Progress Guidance at 1-4.

²¹ ADEQ's decision to assess reasonable progress controls despite the fact that they are unnecessary is consistent with EPA's Regional Haze Revision Rule, 82 Fed. Reg. at 3,089, which mandates that states assess controls even before they establish their reasonable progress goals and that visibility not be considered as a factor in determining whether to require controls. For the reasons explained in this section, this is inconsistent with the CAA. Entergy Services, Inc. submitted a petition for reconsideration to EPA on this issue on March 13, 2017. *See* Petition for Reconsideration of the Revisions to the Regional Haze Rule by Southwestern Public Service Company, Entergy Services, Inc., and Cleco Power LLC, Docket No. EPA-HQ-OAR-2015-0531-0641 (Mar. 13, 2017) (attached as Exhibit F). On January 17, 2018, EPA determined that it would review the Regional Haze Revision Rule. *See* Letter from Scott Pruitt, EPA, to Debra J. Jezouit and Allison Watkins Mallick, Baker Botts L.L.P. (Jan. 17, 2018) (attached as Exhibit G). As a result, these mandates may be revised or eliminated.

2. *Any final reasonable progress assessment should broadly consider all relevant sources and factors.*

If ADEQ determines a reasonable progress analysis is required, it should perform a broader analysis than the one conducted for the Draft SIP. Specifically, such an analysis should look at all relevant sources as well as beyond the four statutory reasonable progress factors. *See* 42 U.S.C. § 7491(g)(1) (requiring the consideration of (1) non-air quality environmental impacts, (2) cost of compliance, (3) time necessary for compliance, and (4) remaining useful life).

ADEQ is not limited to consideration of the four factors mandated by the CAA; instead, states are specifically authorized by EPA’s guidance to consider other relevant factors, and Arkansas should do so here. EPA’s Reasonable Progress Guidance, which applies to the first planning period, is clear that the four statutory factors are the *minimum* that ADEQ must consider. In other words, when determining reasonable progress, states can consider other factors that it has found to be relevant. *See* Reasonable Progress Guidance at 5-1 (“In determining reasonable progress, CAA § 169A(g)(1) requires States to take into consideration a number of factors. However, you have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant.”). For example, there is no requirement that the analysis mirror a BART analysis. To the contrary, EPA has stated that

[u]nlike the technical demonstration for...BART, the reasonable progress demonstration involves a test of strategy. The strategy includes a suite of controls that has been identified through the identification of pollutants and source categories of pollutants for visibility impairment—the possible controls for these pollutants (and their precursors) and source categories—the application of four statutory factors and how much progress is made with a potential strategy and is not a source-specific demonstration like the BART assessment.²²

²² EPA, Additional Regional Haze Questions, at 8 (Sept. 27, 2006 Revision).

EPA also has explained that the cost of compliance factor for reasonable progress purposes – one of the factors that overlaps with a BART analysis – “can be interpreted to encompass the cost of compliance for individual sources or source categories, and more broadly the implication of compliance costs to the health and vitality of industries within a state.” Reasonable Progress Guidance, at 5-1.

There are several other relevant factors that ADEQ should consider. Most importantly, ADEQ should look broadly at the sources contributing to visibility impairment at Class I areas instead of focusing solely on Independence. As explained in Entergy’s comments on the Proposed FIP, Arkansas point sources are relatively insignificant contributors to visibility impairment in Caney Creek and Upper Buffalo compared to most of the other regions modeled by CENRAP, and are not the largest source group contributors in Arkansas to visibility impairment in these Class I areas. *See* EAI Arkansas FIP Comments at 23-29. Of a total point source contribution of 61.85% at Caney Creek in 2002, Arkansas’ point sources contributed only 2.87%, making Arkansas the eighth highest point source contributor. Similarly, of the 60.35% total point source contribution at Upper Buffalo in 2002, Arkansas was the ninth highest point source contributor with only a 2.47% contribution. *Id.* at 26. In addition, most of Arkansas’ share of the contribution to visibility impairment comes from Arkansas area and mobile sources, not point sources. *Id. See also* Draft SIP at 39. At Caney Creek, Arkansas area sources contribute 3.75% of the overall extinction while Arkansas’ combined point source category (i.e., elevated and low-level point sources) contribute only 2.87%. EAI Arkansas FIP Comments at 29. Even more significantly, Arkansas area sources contribute 5.09% towards extinction at Upper Buffalo compared to a mere 2.47% from the combined Arkansas point sources. *Id.* Independence’s emissions, which comprise only a portion of Arkansas’ point source emissions, have an even smaller effect on light extinction in either Class

I area. As a result, installing emissions controls on Independence would not meaningfully change visibility at either Class I area. *See* EAI Arkansas FIP Comments at 23-29.

Evidence of significant contribution to visibility impairment from other sources is a valid consideration when assessing reasonable progress controls and has been approved by EPA in other similar decisions. *See, e.g.*, Proposed Rule: Approval and Promulgation of Implementation Plans; State of Alaska; Regional Haze State Implementation Plan, 77 Fed. Reg. 11,022, 11,035-36 (Feb. 24, 2012) (EPA proposing to approve Alaska’s conclusion that it is not reasonable to require reasonable progress controls, in part because emissions from natural sources contribute the most significant visibility impacts); 78 Fed. Reg. 10,546 (Feb. 14, 2013) (final approval). In fact, EPA approved ADEQ’s decision to screen out Arkansas point sources from further evaluation of NOx controls for reasonable progress purposes in light of (1) the low level of visibility impairment due to NOx emissions from those sources and (2) the fact that additional NOx controls are not anticipated to yield meaningful visibility improvements. Phase I SIP Approval at 11-12, 22-23. EPA explained that, “in cases where it has been demonstrated that a particular pollutant or source category does not contribute significantly to visibility impairment at affected Class I areas, it may be appropriate to end the analysis at that point, without the need to evaluate the four statutory factors for potential controls to address that pollutant and/or source category.” *Id.* at 26. As with NOx, Independence’s SO₂ emissions have a small contribution to visibility impairment, as demonstrated in Entergy’s CAMx modeling, and installation of SO₂ controls at Independence would have little impact on visibility. *See* EAI Arkansas FIP Comments at 32. Based on EPA’s approval of ADEQ’s NOx analysis, consideration of these factors is appropriate.

ADEQ also should assess costs in the context of effects on electricity rates. Installation of Dry FGD at Independence would cost approximately *\$1 billion*. These costs could increase

electricity rates, with significant impacts on Arkansas communities, many of which already are facing economic hardships. This is unreasonable in light of the current visibility in Arkansas' Class I areas.

3. *If the Final SIP relies on a source-specific four-factor analysis, the analysis should be revised.*

To the extent ADEQ continues to rely on an Independence-specific four-factor analysis in the final SIP, its analysis should be revised in several ways. ADEQ should revise its estimate of the costs of compliance on a dollar-per-deciview basis. ADEQ also should recognize the time necessary for compliance. Finally, and most importantly in the context of a source-specific analysis, ADEQ should account for the remaining useful life of Independence. ADEQ should revise any final four-factor analysis to account for these factors, to ensure consideration of the most up-to-date relevant information, to strengthen the SIP and its strategy for subsequent planning periods, and, simply, to comply with the requirements of the CAA. A corrected analysis including these revisions would support a determination that no controls are warranted on Independence for reasonable progress in the first planning period.²³

- (i) ADEQ should revise its estimated dollar-per-deciview costs of compliance.

Entergy agrees with ADEQ that the costs of control technologies like Dry FGD in terms of dollar-per-deciview of improvement is an important metric for assessing the cost of compliance. See Draft SIP at 45. However, ADEQ should revise its dollar-per-deciview calculations to more accurately estimate the cost of controls. ADEQ relied on cost information and modeling results from the Final FIP to calculate these values, resulting in an underestimation of costs. ADEQ

²³ Nonetheless, as explained in Section II.C, *infra*, EAI is willing to implement LSC as a SIP-strengthening measure.

estimates that the cost of Dry FGD at Independence is approximately \$67 million per dv improvement at Caney Creek, and approximately \$62 million per dv improvement at Upper Buffalo. *Id.*

As explained in Entergy's comments on the Proposed FIP, the cost of Dry FGD at Independence is actually much higher: approximately \$1.33 billion \$1.35 billion per dv improvement at Caney Creek and Upper Buffalo respectively. *See* Sargent & Lundy, *Review of EPA's Cost Analysis for Arkansas Regional Haze Proposed Federal Implementation Plan*, Report No. SL-012913, (July 15, 2015) (attached as Exhibit D). Instead of relying on CALPUFF, Entergy's calculations rely on CAMx modeling, which is a more appropriate modeling tool for assessing Regional Haze, especially reasonable progress. CALPUFF modeling vastly overstates the potential visibility improvement from controls on Independence. *See* EAI Arkansas FIP Comments at 35-41. The true costs of Dry FGD are exorbitant and cannot be justified where additional visibility improvement is not needed to remain below the glide path. *See Nat'l Parks Conservation Ass'n v. EPA*, 788 F.3d 1134, 1149 (9th Cir. 2015) ("NPCA") (upholding EPA's decision not to require reasonable progress controls because of lack of cost-effectiveness).

(ii) ADEQ should consider the actual time necessary for compliance.

Neither Dry FGD, DSI, nor LSC can be considered reasonable progress controls for Independence, as none of these controls could be implemented before the end of the first planning period in 2018. EPA's regulations require SIPs to consider "the emission reduction measures needed to achieve [reasonable progress goals] *for the period covered by the implementation plan.*" 40 C.F.R. § 51.308(d)(1)(i)(B) (emphasis added). The use of LSC cannot occur until the second planning period due to the existing coal contracts that already dictate Entergy's coal supply

through 2019.²⁴ In staying the effectiveness of EPA’s Regional Haze FIP for the state of Texas, the U.S. Court of Appeals for the Fifth Circuit explained that “[t]he emissions controls included in a state implementation plan . . . must be those designed to achieve the reasonable progress goal for the period covered by the plan,” and that the parties challenging the FIP “persuasively argue that [EPA’s requirement that power plants meet Reasonable Progress goals by installing scrubbers in 2019 and 2021] exceeds the power granted by the Regional Haze Rule.” *Texas v. EPA*, 829 F.3d 405, 429 (5th Cir. 2016). ADEQ has not explained why it is appropriate to require reasonable progress controls in a SIP for the first planning period when the controls cannot be installed or result in visibility benefits in that planning period.

(iii) ADEQ should account for the anticipated Remaining Useful Life of Independence.

ADEQ should account for the expected remaining useful coal-fired life of Independence in any final four-factor analysis, as required by the CAA. *See* 42 U.S.C. § 7491(g)(1). In its Updated Analysis of Reasonable Progress, Entergy notified ADEQ that it anticipated ceasing to combust coal at the Independence units by the end of 2030.²⁵ *See* Analysis of Reasonable Progress at 6-2. When the coal units’ expected remaining useful life is considered along with the time necessary for compliance with add-on SO₂ emissions controls (e.g. the 5-year compliance deadline in the FIP for the installation of Dry FGD), the cost of controls is unreasonable. For example, according to EAI’s analysis, as based on EPA’s control cost estimates, the cost effectiveness of Dry FGD would be approximately \$5,026/ton of SO₂ removed at Unit 1, and \$4,640/ton of SO₂ removed at Unit 2. *See* Trinity Consultants, *Supplemental Information: Analysis of Reasonable*

²⁴ ADEQ should correct its description of the fuel burned at Independence. While Independence does burn Powder River Basin sub-bituminous coal, this coal is not always from Wyoming. *See* Draft SIP at 42.

²⁵ EAI is willing to take an enforceable commitment to this effect.

Progress Arkansas Regional Haze Program, First Planning Period, at 3-1 (Feb. 2, 2018) (attached as Exhibit I).

These control costs are not reasonable, as they exceed cost effectiveness values that EPA agreed could be rejected for reasonable progress purposes for other state plans. For example, the Kentucky Regional Haze SIP used a value of \$2,000 per ton SO₂ as a screening threshold for cost effectiveness. 76 Fed. Reg. 78,194, 78,206 (Dec. 16, 2011). These control costs are especially unreasonable where the visibility already meets the reasonable progress goal. In the North Carolina Regional Haze SIP, EPA approved the state's decision not to implement reasonable progress controls due to limited improvement in visibility even though cost effectiveness values were described as ranging "from 912 to 1,922 dollars per ton of SO₂ removed (\$/ton SO₂), and the average costs per utility system ranged from \$1,231 to \$1,375/ton SO₂." 77 Fed. Reg. 11,858, 11,870 (Feb. 28, 2012). Further, EPA has indicated that control costs found to be reasonable in the BART context may nonetheless be considered too costly in the reasonable progress context. *See* Final North Dakota SIP Approval/Disapproval, 77 Fed. Reg. 20,894, 20,936 (Apr. 6, 2012) (accepting North Dakota's determination that a level of \$2,593 per ton of SO₂ removed was not reasonable and too costly in the reasonable progress context even though it is within the range EPA "ha[s] considered reasonable in the BART context").

C. ADEQ Should Consider EAI's Plans for White Bluff, Lake Catherine, and Independence as Part of its Long-Term Strategy

ADEQ asks EPA to approve the state's revised long-term strategy ("LTS"), which incorporates the proposed BART determinations and reasonable progress controls for Independence, and which would be rendered enforceable in the draft AOs included in Tab C of the Draft SIP. *See* Draft SIP at 54. ADEQ should revise the LTS to account for the anticipated cease-to-use coal dates identified by EAI for White Bluff and Independence, as well as the reduced

NOx emissions that will be achieved at White Bluff and Independence through the installation of controls that currently is ongoing. In addition, Lake Catherine Unit 4 will retire by the end of 2025, as identified in EAI's integrated resource plan and, accordingly, the planned retirement date should be included in the LTS.

These dates and reduced emission rates also should be included in the Entergy AO to make them enforceable, thereby satisfying the requirements of the Regional Haze Rule. A LTS for Regional Haze "must include enforceable emissions limitations, compliance schedules, and other measures as necessary to achieve the reasonable progress goals . . ." 40 C.F.R. § 51.308(d)(3). The regulation is clear that states must consider certain factors, including "emission reductions due to ongoing air pollution control programs" and "source retirement and replacement schedules." *Id.* at § 51.308(d)(3)(v). As discussed previously, Entergy anticipates that it will cease to use coal at White Bluff in 2028 and at Independence in 2030. Additionally, Entergy plans to cease operating Lake Catherine Unit 4 in 2025. Furthermore, low-NOx burners and separated overfire air technology ("LNB/SOFA") already are being installed at White Bluff and Independence, and Entergy will meet appropriate NOx emissions limits based on the testing and tuning of this equipment. Finally, although Entergy disagrees with ADEQ's proposed determination that LSC should be required for Independence as a reasonable progress control, Entergy would agree to take an SO₂ limit for Independence Units 1 and 2 based on the use of LSC at a rate of 0.6 lb/mmBTU on a 30-day rolling average as a SIP-strengthening measure.

These retirement plans, control technology installations, and SO₂ limits should be included in the LTS, pursuant to the requirements of the Regional Haze Rule. *See* Reasonable Progress Guidance at 1-4 ("The long-term strategy is the compilation of 'enforceable emissions limitations, compliance schedules, and other measures as necessary to achieve the [reasonable progress

goals],’ and is the means through which the State ensures that its [reasonable progress goal] will be met.”). Including these developments in the AO applicable to Entergy will make them enforceable, as required by the regulations, and ensure that ADEQ has a defensible long-term strategy that maintains Arkansas’ Class I areas on the glidepath.

D. ADEQ Should Not Readdress BART Determinations Previously Approved by EPA

Almost six years ago, EPA approved ADEQ’s PM BART determinations for White Bluff Units 1 and 2, and the SO₂ and PM BART determinations for the natural gas firing scenario for Lake Catherine Unit 4. 77 Fed. Reg. 14,604, 14,607 (Mar. 12, 2012). Nonetheless, ADEQ identifies these BART determinations in the Draft SIP, requests that EPA re-approve them, and proposes to include the existing PM and SO₂ requirements in the AO for these units. This is confusing, unnecessary, and re-opens these long-settled BART determinations for additional review and comment.

These BART determinations already are in effect and were included in the plants’ Title V permits as enforceable emissions limits. ADEQ has offered no basis for EPA to reevaluate these BART determinations. An opportunity for public comment on the BART limitations already was provided and EPA approved them almost six years ago. BART is a one-time requirement—neither the CAA nor EPA’s Regional Haze regulations provide a basis to review and reevaluate approved BART determinations. *See* 42 U.S.C. § 7491(g)(2) (identifying the steps for determining BART, with no mention that this analysis ever be reevaluated); 40 C.F.R. § 51.308(e) (providing no indication that a state must resubmit an implementation plan that already has been approved). EPA’s BART Guidelines similarly provide no indication that BART should be revisited. *See* 40 C.F.R. Pt. 51, App. Y.

Because the Draft SIP contains no new information about these already-approved BART limits, ADEQ has no basis to address them in its final SIP. Further, it is unnecessary to include these limits in an AO. They already are enforceable through the plants' Title V permits and have been since 2007.²⁶ ADEQ has offered no explanation as to why it would be necessary for EAI to enter into an AO establishing these limits given that they are already approved into the SIP and are separately enforceable through the plants' Title V permits.

If ADEQ is interested in moving these BART limitations into a different section or chapter of its SIP-approved regulations, it can do so through administrative changes to its regulations rather than asking EPA to eliminate them from the SIP and reapprove them. The process ADEQ has proposed in the Draft SIP is unnecessary and confusing.

E. ADEQ Should Revise the Proposed Entergy Administrative Order

ADEQ should make a number of revisions to the proposed AO for Lake Catherine, White Bluff, and Independence.²⁷ Draft SIP, Tab C: Evidence of Adoption of the Plan into Administrative Orders, *In the Matter of: Entergy Arkansas, Inc.* ("Draft EAI AO").

- Lake Catherine Unit 4 no longer has the capability to burn fuel oil; in fact, fuel oil combustion has been removed from the plant's Title V permit. In light of this, there is no need for the SIP to restrict fuel oil burning at Unit 4 until a BART determination for fuel oil has been made. *See* Draft SIP at 20; Draft EAI AO Order #7. This requirement should be removed.

²⁶ The PM limits for all three units are included in their respective permits. ADEQ's approved SO₂ determination for Lake Catherine Unit 4 was that no SO₂ limit was necessary due to natural gas combustion. 77 Fed. Reg. at 14,653.

²⁷ As explained in footnote 3, EAI reserves the right to continue to work with ADEQ on the terms of the AO.

- As discussed above in Section II.D, EPA approved PM BART determinations in 2012 for White Bluff Units 1 and 2, and SO₂ and PM BART determinations for the natural gas firing scenario for Lake Catherine Unit 4. 77 Fed. Reg. at 14,607. These limits have been incorporated into the plants' Title V permits, as appropriate. Therefore, these PM and SO₂ limits should be eliminated from the AO, as their inclusion is unnecessary.
- Finding of Fact #8 should be revised to omit the discussion of the impacts of the White Bluff and Lake Catherine units on Arkansas Class I areas, as this discussion is not accurate.
- ADEQ should eliminate the requirement in Order #8 that compliance with emissions limits for SO₂ and NO_x be determined using data from a continuous emission monitoring system ("CEMS"). This requirement would mandate the installation of a CEMS on the White Bluff Auxiliary Boiler, which is unnecessary for a unit that operates so infrequently. EPA appears to have acknowledged this given its omission of such a requirement in the Final FIP. *See* 81 Fed. Reg. at 66,416. It also could be interpreted to require CEMS for Lake Catherine Unit 4, which currently continuously monitors natural gas flow to the unit along with periodic determination of the gross calorific value ("GCV") and sulfur content of the natural gas, in accordance with 40 C.F.R. Part 75 requirements. For NO_x emissions, a NO_x correlation test is conducted once every five years to establish a NO_x emission rate vs. heat input correlation curve, which is used to calculate NO_x emissions from the unit. This procedure complies with 40 C.F.R. Part 75, Appendices D and E, and is appropriate for a peaking unit with a typical annual

capacity factor of <10%. EPA determined in the Final FIP that this methodology was acceptable. *See* 81 Fed. Reg. at 66,418.

- The AO should include the expected cease-to-use coal dates for White Bluff and Independence, and the retirement date for Lake Catherine, for the reasons discussed in Section II.C, *supra*.

F. Technical Comments

ADEQ should make the following corrections to eliminate errors or incorrect data in its calculations and technical analyses.

- **LSC is not an Existing Control.** ADEQ concludes that LSC is an “existing control” at White Bluff and Independence because the plants have achieved SO₂ emissions rates significantly lower than the permitted limits through use of LSC. This is inaccurate. ADEQ notes that White Bluff has been able to achieve monthly average emissions rates below 0.69 SO₂/MMBtu, compared with its permitted emissions rate of 1.2 lb SO₂/MMBtu, Draft SIP at 22, and that Independence has been able to achieve 30-boiler-operating-day average emissions rates in the range of 0.48–0.63 lb SO₂/MMBtu, compared with its permitted emissions rate of 0.93 lb/MMBtu. *Id.* at 43. ADEQ is improperly comparing emissions averaged on a *monthly* basis with the permit limits, which are averaged on a *3-hour* basis. The two are not comparable. Due to natural variability in the sulfur content of coal, long-term average emissions must be lower than the short-term limit to ensure compliance with a short-term 3-hour emission limit. For example, the maximum 3-hour average emission rate at White Bluff from 2014-2016 was 1.1 lb/MMBtu even though monthly averages were lower.

- **Characterization of Total Annualized Costs.** ADEQ’s calculations of annualized costs for DSI, enhanced DSI, and Dry FGD include the annualized costs for LSC. See Draft SIP at 23, Table 4; ADEQ, *White Bluff Cost Calculations*, available at <https://www.adeg.state.ar.us/air/planning/sip/regional-haze.aspx>. ADEQ provides no basis for its assumption that LSC would be implemented in addition to these other controls. Accordingly, the annualized costs for DSI, enhanced DSI, and Dry FGD should not include costs for LSC.
- **Description of Visibility Improvements from LSC at Independence.** In its Independence-specific reasonable progress analysis, ADEQ states: “Because Entergy Independence frequently achieves less than or equal to the 0.6 lb/MMBtu emission rate associated with LSC, ADEQ has not modeled visibility impacts for the LSC scenario.” Draft SIP at 46. ADEQ’s characterization of the SO₂ emission rate is misleading and should be deleted. While Entergy believes that no controls are required for reasonable progress at Independence, an SO₂ emission rate of 0.6 lb/mmBTU on a 30-day rolling average at Independence based on the use of LSC would yield a visibility improvement of 0.112 Δdv for Caney Creek and 0.302 Δdv for Upper Buffalo.²⁸
- **ADEQ should correct errors in the CENRAP-PSAT values.** ADEQ states incorrectly that “other source categories each contribute between two percent and six percent of total light extinction at Arkansas Class I areas.” Draft SIP at 29. The

²⁸ Trinity Consultants, Inc. performed CALPUFF modeling to assess the visibility impacts for the LSC scenario. See Trinity Consultants, *CALPUFF Modeling for Low Sulfur Coal Scenario* (Jan. 3. 2018), attached as Exhibit H. Although Entergy believes CAMx modeling would provide more accurate estimates of visibility improvement, Trinity did not have sufficient time to perform CAMx modeling in the time period provided for public comment on the Draft SIP.

six percent value should be corrected to seven percent. ADEQ also vaguely characterizes the contribution of natural, on-road, and non-road sources as “a very small portion of total light extinction.” ADEQ should clarify that these sources contribute approximately five percent to total light extinction, rather than providing a subjective characterization of their contribution as “very small.” Finally, values presented as “0” in Figures 6, 7, 8, and 9 should be expanded to show at least one non-zero digit, or should be footnoted to clarify that they are not zero.

III. Conclusion

Entergy appreciates the opportunity to comment on the Draft SIP, and has endeavored to suggest changes that would ensure the final SIP is legally defensible in the event of a challenge. Entergy agrees with ADEQ’s proposed BART SO₂ limits for White Bluff Units 1 and 2, but urges ADEQ to revise its underlying BART analysis, as well as its assessment of reasonable progress controls for Independence. Entergy also urges ADEQ to revise its LTS and the draft AO for Entergy’s units to ensure anticipated emission reductions are durable and enforceable. Finally, Entergy appreciates ADEQ’s consideration of the various corrections and amendments to the Agency’s proposed AO and technical analyses to support the SIP. Entergy believes its comments will assist ADEQ to develop a final SIP that is legally supportable and will provide the company with regulatory certainty.

Respectfully submitted,

Kelly M. McQueen

Re: Petition for Reconsideration and Request for Stay of Entergy Arkansas Inc. et al.
of the Arkansas Regional Haze and Interstate Visibility Transport Federal
Implementation Plan, EPA Docket No. EPA-R06-OAR-2015-0189

Dear Administrator Curry:

Entergy Arkansas Inc., Entergy Mississippi Inc., and Entergy Power, LLC (collectively "Entergy") respectfully submit the enclosed Petition for Reconsideration and Request for Stay ("Petition") of the U.S. Environmental Protection Agency's ("EPA" or "Agency") final "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan" ("Final FIP"). 81 Fed. Reg. 66,332 (Sept. 27, 2016).

The Petition includes exhibits that contain Confidential Business Information for Entergy and for a third party. The exhibits have been partially redacted to remove non-pertinent information and are clearly marked as "Redacted and Confidential Business Information." Entergy also is providing a copy of the exhibits without the aforementioned confidential exhibits. Due to their length, both versions of the exhibits to the Petition are being provided on the enclosed CDs. An additional copy of the Petition is enclosed to be time-stamped and returned in the attached envelope.

Thank you for your consideration of the enclosed Petition for Reconsideration and Request for Stay. If you have any questions, please contact me at (202) 639-7728.

Sincerely,

Debra J. Jezouit
Counsel to Entergy Services Inc.

Enclosures

**Petition for Reconsideration and Request for Stay of Entergy Arkansas Inc., et al., of the
Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and
Interstate Visibility Transport Federal Implementation Plan**

Entergy Arkansas Inc. (“EAI”), Entergy Mississippi Inc. (“EMI”), and Entergy Power, LLC (collectively “Entergy”) respectfully submit this petition for reconsideration and request for stay (“Petition”) of the U.S. Environmental Protection Agency’s (“EPA” or “Agency”) final “Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan” (“Final FIP”).¹ As discussed below, Entergy requests that EPA reconsider and stay elements of the Final FIP that relate to Entergy’s White Bluff and Independence plants. To avoid the significant, irreparable harms that already have begun to occur, Entergy respectfully requests that EPA take action on this Petition by February 1, 2017. The administrative stay requested by Entergy would not cause adverse visibility impacts in Arkansas’ Class I areas.

I. INTRODUCTION AND SUMMARY

The Final FIP affects four coal-fired electric generating units owned by Entergy: two at the White Bluff Electric Power Plant (“White Bluff”) and two at the Independence Steam Electric Station (“Independence”), which will impose costs on Entergy, its co-owners and its customers of approximately \$2 billion for minimal visibility benefits. Specifically, the Final FIP requires each coal-fired unit at White Bluff and Independence to meet a sulfur dioxide (“SO₂”) emission limit of 0.06 lb/MMBtu by October 27, 2021.² This emission limit is based on the installation of a dry scrubber (flue gas desulfurization (“FGD”) technology) on each unit. The Final FIP also will require each coal-fired unit to meet a nitrogen oxides (“NO_x”) emission limit of 0.15 lb/MMBtu on a rolling 30-boiler operating day basis at loads of 50-100 percent of maximum heat input rating, and a rolling 3-hour average limit of 671 lb/hr at loads of less than 50 percent of maximum heat input rating.³ These emission limits, which must be met beginning

¹ 81 Fed. Reg. 66,332 (Sept. 27, 2016).

² *Id.* at 66,339, 66,416, 66,420.

³ *Id.* at 66,416-17.

April 27, 2018, are based on the installation of low-NOx burners and separated overfire air (“LNB/SOFA”) on each unit.

The Petition must be granted because EPA failed to provide adequate notice and opportunity to comment on significant, burdensome requirements in the Final FIP that affect the requirements imposed on Entergy’s units, are of central relevance to the outcome of the Final FIP, and are not logical outgrowths of the proposed rule (“Proposed FIP”).⁴ Additionally, the Final FIP contains clear errors that must be corrected. These administrative shortcomings demand reconsideration and a stay of key elements of the Final FIP. Specifically, Entergy requests that EPA reconsider the following:

- the imposition of reasonable progress controls on Independence;
- EPA’s determination that dry FGD technology constitutes best available retrofit technology (“BART”) for White Bluff for SO₂ emissions;
- the 18-month deadline for installation of NOx controls at White Bluff and Independence;
- the adoption of source-specific NOx BART in lieu of reliance on the emissions reductions resulting from implementation of the Cross-State Air Pollution Rule (“CSAPR”);⁵ and
- the NOx limit and three-hour averaging period for NOx compliance that applies when units at White Bluff and Independence operate at low loads.

A stay of certain requirements in the Final FIP is necessary because justice so requires and to avoid irreparable harm to Entergy and its co-owners, customers, and communities while EPA reconsiders the Final FIP, and while the U.S. Court of Appeals for the Eighth Circuit (“Eighth Circuit”) considers Entergy’s petition for review of those requirements.⁶ The pollution controls at White Bluff and Independence required by the Final FIP would cost approximately \$2 billion to design, permit, purchase, and install. Absent a stay, Entergy will be forced to make a costly Hobson’s choice: (1) commence designing, permitting, purchasing, and installing the required controls immediately; or (2) commence planning to decommission White Bluff and Independence by the Final FIP compliance deadline in 2021. Either course of action causes irreparable harm. The first option would require Entergy to expend \$150 million or more just within the next 18 months that could be rendered entirely unnecessary by a grant of reconsideration. The second option would require an array of costly steps planning for decommissioning the units and would ultimately lead to a host of significant harms to Entergy and its co-owners, customers, and local economies. Furthermore, Entergy could not avoid these harms by changing course at a later date, because it will either already have expended multiple millions of dollars on equipment that will serve no purpose (if it initially selected the first option), or it will be too late to install the controls in time to meet the deadline (if it initially selected the second option).

⁴ 80 Fed. Reg. 18,944 (Apr. 8, 2015).

⁵ See Petition for Reconsideration and Request for Administrative Stay of Arkansas Department of Environmental Quality, at 5-8 (Nov. 22, 2016) (hereinafter “ADEQ Petition”).

⁶ Specifically, Entergy seeks a stay of 40 C.F.R. §§ 52.173(c)(6)-(8) with respect to White Bluff and §§ 52.173(c)(24)-(26) with respect to Independence.

A stay would avoid irreparable harm yet would have no adverse impact on visibility in either Arkansas Class I area, as monitoring data show that current visibility already is better than the reasonable progress goals (“RPGs”) established by EPA for this implementation period and that visibility in the Class I areas continues to improve.

Immediate action on this Petition is urgently needed to avoid the harms described herein. Therefore, Entergy respectfully requests that EPA take action in response to this Petition by February 1, 2017. In the absence of a grant of reconsideration and stay by that time, Entergy will consider the Petition to be denied, unless the parties have jointly agreed to a longer period of time for EPA to take action on the Petition.

II. DESCRIPTION OF PETITIONERS

EAI is an electric utility engaged primarily in the generation, purchase, transmission, distribution and sale of electricity in portions of Arkansas. EAI provides electrical utility service to approximately 712,000 electric customers, deriving 81 percent of its operating revenues from electric customers in 2015. EAI owns portions of White Bluff and Independence and operates both plants. EAI is a regulated utility company subject to the rate and general operating jurisdiction of the Arkansas Public Service Commission (“APSC”) and the Federal Energy Regulatory Commission (“FERC”). All of the common stock of EAI is owned by Entergy Corporation.

EMI is an electric utility engaged primarily in the generation, purchase, transmission, distribution and sale of electricity in portions of Mississippi, and is a co-owner of Independence. EMI provides electrical utility service to approximately 447,000 electric customers, deriving 89 percent of its operating revenues from electric customers in 2015. EMI is a regulated utility company subject to the rate and general operating jurisdiction of the Mississippi Public Service Commission and FERC. All of the common stock of EMI is owned by Entergy Corporation.

Entergy Power, LLC is an electric utility company that sells electric energy at wholesale and is a co-owner of Independence. Its principal business office is located in Little Rock, Arkansas. Entergy Power, LLC is an indirect wholly owned subsidiary of Entergy Corporation.

III. REQUEST FOR RECONSIDERATION

A. Reconsideration Is Required Under Clean Air Act Section 307(d)(7)(B).

EPA *must* grant reconsideration of a final action when a petitioner “can demonstrate to the Administrator that it was impracticable to raise [an] objection [during the period for public comment] or if the grounds for such objection arose after the period for public comment (but within the time specified for judicial review) and if such objection is of central relevance to the outcome of the rule.”⁷ In such a situation, reconsideration is mandatory, as the Clean Air Act (“CAA”) commands that EPA “*shall* convene a proceeding for reconsideration of the rule and provide the same procedural rights as would have been afforded had the information been available at the time the rule was proposed.”⁸ EPA must grant this Petition because

⁷ 42 U.S.C. § 7607(d)(7)(B).

⁸ *Id.* (emphasis added).

(1) Entergy's objections are to actions EPA took in the Final FIP, or developments since the comment period closed, and thus could not have been raised during the comment period on the Proposed FIP; (2) the objections arose during the period for judicial review; and (3) the objections are of central relevance to the outcome of this rulemaking.

Reconsideration also is appropriate to correct clear errors, as the CAA provides for judicial invalidation of rules if errors are "so serious and related to matters of such central relevance to the rule that there is a substantial likelihood that the rule would have been significantly changed if such errors had not been made."⁹ EPA should grant this Petition to address serious errors that are of central relevance to the Final FIP.

B. EPA Should Reassess its Imposition of Reasonable Progress Controls on Independence in Light of More Recent Air Quality Data and Corrected Contribution Data.

Data that became available after the close of the public comment period on the Proposed FIP confirm that reasonable progress controls on Independence for the first planning period are wholly unnecessary. Additionally, EPA's reasonable progress analysis relies on a false characterization of Independence's contribution to visibility impairment in Class I areas. EPA should reconsider the Final FIP and the controls on Independence in light of more recent air quality data, as well as corrected data regarding Independence's contribution to visibility impairment.

According to Interagency Monitoring of Protected Visual Environments ("IMPROVE") monitoring data for 2015, which became available subsequent to the close of the comment period, visibility continues to improve at a greater rate than the uniform rate of progress ("URP") in the Caney Creek Wilderness Area ("Caney Creek") and the Upper Buffalo Wilderness Area ("Upper Buffalo").¹⁰ In addition, the recent IMPROVE data further confirm that visibility in the two Arkansas Class I areas already is better than the RPGs that EPA finalized for the areas. EPA set the RPGs for the 20 percent worst days at 22.47 deciviews ("dv") for Caney Creek and at 22.51 dv for Upper Buffalo.¹¹ The recent IMPROVE data for both Class I areas demonstrate that monitored visibility impairment in the areas already is well below EPA's RPGs, as well as Arkansas' RPGs, and that visibility impairment is continuing to trend downward.¹² Given that Caney Creek and Upper Buffalo already have surpassed the URP goals, Arkansas' RPGs, and EPA's final RPGs for the first planning period, reasonable progress controls during the first planning period are not "*necessary*" to ensure reasonable progress towards the natural visibility goal.¹³ There is simply no standard of reasonable progress that necessitates controls on

⁹ 42 U.S.C. § 7607(d)(8).

¹⁰ Assessment of Recent Class I Area IMPROVE Monitoring Data prepared by Trinity Consultants, Inc., at 3 (Aug. 8, 2016, updated Nov. 15, 2016) (hereinafter "Trinity Report") (attached as Exhibit A).

¹¹ 81 Fed. Reg. at 66,354.

¹² Trinity Report at 3. Actual visibility impairment at Caney Creek in 2015 was 20.41 dv, below Arkansas' RPG of 22.48 dv and EPA's final RPG of 22.47. Actual visibility impairment at Upper Buffalo in 2015 was 19.96 dv, below Arkansas' RPG of 22.52 and EPA's final RPG of 22.51. *Id.*

¹³ See 42 U.S.C. § 7491(b)(2) (requiring regional haze implementation plans to contain measures "necessary to make reasonable progress toward meeting the national goal").

Independence for this planning period, especially in light of the fact that the Regional Haze Program is designed to achieve its goals over a long horizon – by 2064.

EPA also should reconsider the need for NO_x controls on Independence based on a corrected understanding of the plant's contribution to visibility impairment. In the Final FIP, EPA justified the need for NO_x controls on Independence based on a false characterization of the plant's contribution to visibility impairment. EPA stated that, "Entergy's CAMx modeling shows that nitrate from Independence is responsible for 30 – 40% of the visibility impairment in Arkansas' Class I areas on 2 of the 20% worst days."¹⁴ This statement is false and must be corrected. EPA's statement indicates that on two of the 20 percent worst days, *30-40 percent of all impairment* at Arkansas' Class I areas is due to nitrates derived from NO_x emissions from Independence. In reality, *30-40 percent of the impairment on these days that is due to nitrates* is attributable to Independence. But nitrates are a minute portion of visibility impairment at Arkansas' two Class I areas. The average total nitrate contribution from Independence to visibility impairment on these days is only 0.02 percent at Upper Buffalo and 0.03 percent at Caney Creek. Thus, the actual contribution is over three orders of magnitude less than EPA stated.

Entergy had no opportunity to comment on this mischaracterization of Independence's nitrate contribution to visibility impairment, which is of central relevance to the outcome of the rule. EPA should correct this mischaracterization and clearly acknowledge that the contribution of Independence to visibility impairment in Arkansas' Class I areas is almost meaningless.

In sum, EPA should reconsider the necessity of reasonable progress controls for Independence in light of the recent IMPROVE monitoring data as well as a corrected assessment of Independence's contribution to visibility impairment in Arkansas' Class I areas.

C. The SO₂ BART Determination in the Final FIP for White Bluff Failed to Consider Critical Information.

1. EPA materially misunderstood Entergy's comments regarding EPA's proposed SO₂ BART determination for White Bluff.

The Final FIP imposes SO₂ limits on White Bluff Units 1 and 2 premised on the installation of dry FGD, which EPA found to be cost-effective based on a 30-year amortization period.¹⁵ EPA failed to consider Entergy's proposal to cease combusting coal in 2027 and 2028, which would limit the remaining useful coal-fired lives of the units and significantly alter the cost-effectiveness of SO₂ controls.¹⁶ Entergy had no notice of or opportunity to timely comment

¹⁴ 81 Fed. Reg. at 66,359.

¹⁵ *Id.* at 66,335, 66,360.

¹⁶ Entergy Arkansas Inc. Comments on the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 5 (Aug. 7, 2015) (Docket ID No. EPA-R06-OAR-2015-0189-0153) (hereinafter "EAI Comments") (attached as Exhibit B).

on EPA's failure, which was only evident in the Final FIP and EPA's associated Response to Comments.¹⁷

In the Final FIP, EPA unreasonably mischaracterized Entergy's White Bluff proposal, resulting in the Agency's failure to properly determine BART for White Bluff Units 1 and 2. EPA acknowledged that a binding requirement to cease combustion of coal at White Bluff would limit the remaining useful lives of Units 1 and 2 for the purpose of evaluating SO₂ controls, but mistakenly assumed that Entergy had not offered such a proposal. EPA explained, "If Entergy's alternative proposal had included accepting a binding requirement to burn only natural gas at White Bluff Units 1 and 2 after coal combustion ceases, or a binding requirement to completely shut down the units, *then we would agree that it would be appropriate to assume that SO₂ emissions from White Bluff will be zero beginning in 2027/2028.*"¹⁸ However, contrary to EPA's assertion, Entergy explicitly made such a commitment in its comments on the Proposed FIP:

As part of a multi-unit plan to improve visibility and to better manage its generation assets for reliability and costs, Entergy proposes to cease burning coal at White Bluff Units 1 and 2 by 2027 and 2028, one unit per year, *and is prepared to take an enforceable commitment to that effect.*¹⁹

EPA's conclusion that Entergy "does not propose...adopting a binding requirement to burn only natural gas or completely shut down the units"²⁰ is inexplicable in light of the plain language of Entergy's proposal. Because EPA determined that a binding requirement to cease burning coal would allow the Agency to assume that SO₂ emissions would be zero subsequent to the cessation of coal combustion, EPA must reconsider the SO₂ BART determination for White Bluff. Failure to do so is unreasonable and arbitrary and capricious.

EPA also asserted that Entergy's proposal to cease using coal at White Bluff appeared tied to EPA's acceptance of Entergy's separately proposed emission limits for Independence.²¹ That assertion is incorrect. Nowhere in its comments did Entergy claim that its acceptance of a binding requirement to cease burning coal at White Bluff Units 1 and 2 was contingent on EPA's agreement to the emission limits that Entergy was proposing for Independence. Although Entergy proposed an approach addressing all four coal-fired units at White Bluff and Independence and provided modeling of its proposal demonstrating that its approach would achieve virtually the same visibility benefits as EPA's Proposed FIP for significantly less cost,²² Entergy did not indicate that its proposed emission limits for Independence were a necessary element of its White Bluff proposal. In fact, in its comments, Entergy explicitly stated that the

¹⁷ 81 Fed. Reg. at 66,335, 66,360; Response to Comments for the Federal Register Notice for the State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan, at 52-54 (Aug. 31, 2016) (Docket ID No. EPA-R06-OAR-2015-0189-0187).

¹⁹ EAI Comments at 5 (emphasis added).

²⁰ 81 Fed. Reg. at 66,356.

²¹ *Id.* at 66,358 ("Entergy's comments provide no indication that it is willing to accept a binding requirement to cease coal combustion at White Bluff by 2027/2028, unless we also accept the elements of its alternative proposal that are applicable to Independence as satisfying the reasonable progress requirements.").

²² EAI Comments at 45-46.

interim emissions reductions it offered, which included the emission limits for Independence, were a *complement* to its proposal for White Bluff.²³

2. EPA did not account for Entergy’s proposal regarding the remaining useful life of White Bluff in analyzing SO₂ controls.

Had EPA appropriately characterized Entergy’s proposal for White Bluff, EPA would have used a shorter remaining useful life for White Bluff in its BART analysis. Proper accounting of remaining useful life is critical because, as EPA acknowledged in the Final FIP, “a shorter remaining useful life [at White Bluff Units 1 and 2] might result in a conclusion that dry scrubbers are not cost-effective....”²⁴ Indeed, as explained in Entergy’s comments, Entergy’s proposal for White Bluff rendered EPA’s proposed BART determination inapplicable, requiring EPA to undertake a new BART analysis to address the remaining useful coal-fired life of the units.²⁵ Because EPA’s FGD cost-effectiveness analysis failed to take into account Entergy’s proposed binding commitment to cease combusting coal at White Bluff, a failure on which Entergy could not previously have provided comment, EPA must reconsider this issue. In doing so, EPA also should reconsider the cost-effectiveness of dry scrubbers in light of the correct control cost information, as explained in the following section.

3. Dry FGD is not cost-effective at White Bluff.

EPA calculates that installing and operating dry FGD at White Bluff would cost \$2,565 per ton of SO₂ removed for Unit 1 and \$2,421 per ton of SO₂ removed for Unit 2.²⁶ However, these cost estimates fail to account for Entergy’s proposal, discussed above, regarding the remaining useful life of the units as well as data regarding the actual cost of controls. Had this information been properly considered, EPA should have estimated that the costs per ton of SO₂ removed would range from approximately \$7,100 to \$8,000 per ton of SO₂ removed, which is patently *not* cost-effective.²⁷

EPA’s cost estimate *failed to include over \$495 million* that Entergy will be required to incur to install dry FGD on the White Bluff units.²⁸ EPA rejected certain costs in the analysis prepared for Entergy by Sargent & Lundy because Entergy did not provide to EPA the underlying 2009 and 2013 Alstom quotes on which Sargent & Lundy’s cost analysis relied.²⁹ Because Entergy had no notice that EPA would require submission of these quotes, which contain non-public, highly confidential and proprietary information, to validate Entergy’s cost analysis, Entergy is providing redacted versions of these quotes now.³⁰ The Alstom quotes

²³ *Id.* at 4 (“Entergy is prepared to offer meaningful interim emission reductions to complement its proposed commitment to cease coal-fired operations at White Bluff and assure that Arkansas remains on a path that is below the URP for the long term.”).

³⁰ 2009 Alstom Report (attached as Exhibit D) and 2013 Alstom Report (attached as Exhibit E). These reports contain confidential business information. Non-pertinent information has been redacted.

demonstrate that EPA improperly excluded extensive costs associated with “Balance of Plant” items, which are items not included in the FGD supplier’s scope, but which are necessary to integrate the FGD system into the plant.³¹ The quotes also demonstrate that EPA underestimated escalation by using the Chemical Engineering Plant Cost Indices (“CEPCI”) instead of relying on more accurate information from the vendor.

The more detailed and accurate cost analysis prepared by Sargent & Lundy, which includes costs improperly excluded by EPA and correctly predicts tons removed, estimates that dry FGD cost-effectiveness will range from approximately \$7,100 to \$8,000 per ton if the units cease combusting coal in 2027-2028.³² Even if certain costs rejected by EPA were excluded in Sargent & Lundy’s cost estimate (i.e., allowance for funds used during construction (“AFUDC”), escalation, and owner’s costs), the cost-effectiveness of dry FGD at White Bluff would range from approximately \$5,400 to \$6,100 per ton.³³ Regardless of which estimate is used, these costs exceed those that EPA has previously rejected in other BART analyses and thus are too high to represent BART for the White Bluff units.³⁴ As a result, dry FGD cannot constitute SO₂ BART for White Bluff Units 1 and 2. Accordingly, EPA should reconsider the White Bluff SO₂ BART.

4. EPA must reconsider SO₂ BART for White Bluff even in the absence of a DSI analysis.

In the Final FIP, EPA argues, for the first time, that it would be necessary to assess dry sorbent injection (“DSI”) as an interim control if the White Bluff units cease to combust coal, and indicates that this lack of DSI analysis somehow negates EPA’s obligation to conduct a reasonable BART analysis of dry FGD at the White Bluff units. Entergy did not have notice of or an opportunity to comment on this assertion, which is of central relevance to the Final FIP. The lack of a DSI analysis, which EPA had not previously requested, does not absolve EPA of its obligation to properly assess the cost-effectiveness of dry FGD.

EPA explains in the Final FIP that “[b]ecause Entergy has provided no analysis to demonstrate that there is no more effective interim SO₂ control that would constitute BART, the company’s proposed strategy is not adequate to ensure that the BART requirements for White Bluff Units 1 and 2 will be met.”³⁵ EPA ties the lack of a DSI analysis to its determination that it

³¹ Upon further review, Sargent & Lundy determined that costs associated with ductwork downstream of the booster fans were included in the Alstom quote. The updated cost estimates in this Petition remove these costs. Sargent & Lundy Memo at 2.

³² *Id.* at 3.

³³ *Id.*

³⁴ EPA declined to impose dry FGD as BART in Arizona, where the average cost effectiveness was estimated to be \$5,090/ton. Proposed Arizona Regional Haze FIP, 79 Fed. Reg. 9,317, 9,331-33 (Feb. 18, 2014); Final Arizona Regional Haze FIP, 79 Fed. Reg. 52,420, 52,436 (Sept. 3, 2014). In North Dakota, EPA approved the state’s determination that a cost effectiveness of \$6,525 per ton was excessive for NO_x controls and did not constitute BART. Proposed North Dakota FIP, 76 Fed. Reg. 58,570, 58,630 (Sept. 21, 2011); Final North Dakota Regional Haze FIP, 77 Fed. Reg. 20,894, 20,896 (Apr. 6, 2012). And, in Montana, EPA concluded that certain SO₂ controls with a cost effectiveness of \$5,442/ton and \$6,365/ton were not cost effective. Proposed Montana Regional Haze FIP, 77 Fed. Reg. 23,988, 24,047 (Apr. 20, 2012); Final Montana Regional Haze FIP, 77 Fed. Reg. 57,864, 57,866 (Sept. 18, 2012).

³⁵ 81 Fed. Reg. at 66,356.

need not even consider Entergy's finding that FGD is not cost-effective in light of its proposal for White Bluff. This is a false premise; the appropriateness of DSI as an interim control measure is irrelevant to the assessment of whether dry FGD is cost-effective. As outlined above, EPA failed to account for the proposed remaining useful life of Units 1 and 2 when assessing dry FGD as a control technology, as well as certain costs associated with such controls, and must do so now on reconsideration. To the extent that EPA *also* believes that an assessment of DSI as a potential control technology is warranted, such assessment is wholly independent of the FGD assessment.

Despite the fact that EPA's request for a DSI analysis arose for the first time in the Final FIP, Entergy is willing to develop and provide the analysis if EPA grants reconsideration on SO₂ BART for White Bluff. Additionally, Entergy understands that the Arkansas Department of Environmental Quality ("ADEQ") will develop a state implementation plan ("SIP") to replace portions of the Final FIP, including the BART controls for White Bluff, and Entergy will submit a DSI analysis to ADEQ, if required, as part of the SIP development process.

D. EPA's LNB/SOFA Assumptions Are Unsupported and Unreasonable, and Must Be Revised.

EPA should reconsider whether NO_x controls should be required for either White Bluff or Independence. As addressed in Section III.A above, NO_x controls on Independence to address reasonable progress are unnecessary for this first planning period. Further, EPA should reconsider its imposition of source-specific NO_x BART controls in the Final FIP and instead determine that compliance with CSAPR is acceptable for compliance with the NO_x BART requirements in Arkansas, including for White Bluff, as addressed more fully in ADEQ's Petition for Reconsideration and Request for Administrative Stay.³⁶

However, if EPA denies reconsideration on these threshold issues, EPA must grant reconsideration on the compliance deadline and NO_x emission limits applicable to both White Bluff and Independence. The compliance deadline and NO_x limits are not logical outgrowths of the Proposed FIP, are not reasonable and fraught with errors, and are of central relevance to EPA's determination of NO_x BART in the rulemaking.

1. EPA must extend the 18-month timeline for the installation of LNB/SOFA to Three Years.

a. The 18-month deadline is not a logical outgrowth of the proposed rule and was promulgated in error.

The Final FIP unlawfully shortens the compliance deadline for the NO_x emission limits for White Bluff and Independence from three years to 18 months.³⁷ EPA proposed a three-year NO_x compliance deadline for these plants and did not indicate in the Proposed FIP that it was considering a shorter deadline. The 18-month deadline is not a logical outgrowth of the proposed compliance deadline. While Entergy stated in its comments that it was prepared to

³⁶ ADEQ Petition at 5-8.

³⁷ 81 Fed. Reg. at 66,338, 66,354.

meet the proposed three-year deadline,³⁸ it lacked notice and had no opportunity to comment on its ability to comply with a shortened compliance deadline.

EPA erred in relying on comments from environmental organizations when contracting the compliance timeline.³⁹ First, the environmental organizations requested a shorter compliance deadline only for White Bluff, not for Independence.⁴⁰ Indeed, while the organizations asserted that LNB/SOFA could be installed on Independence in under a year, the comment concluded that “three years is more than reasonable.”⁴¹ Even if the environmental organizations had requested a shortened compliance deadline for both plants, it is well-established that EPA “cannot bootstrap notice from a comment.” *Small Refiner Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 549 (D.C. Cir. 1983); *Am. Fed’n of Labor v. Donovan*, 757 F.2d 330, 340 (D.C. Cir. 1985).

Further, the environmental organizations’ comments on installation of LNB/SOFA fail to provide a reasonable justification for the shorter compliance timeline. The comments were based on an expert report, which, in turn, relied on a 10-year-old vendor association report that did not consider permitting considerations, a company’s internal project development and approval process, site-specific factors, or reliability concerns.⁴² The vendor association report explicitly recognized that “[v]ariations in the schedule may occur due to site specific conditions that may increase or decrease the typical deployment time.”⁴³ The vendor report also does not appear to allow sufficient time for testing and optimization of equipment, providing only one week for commissioning and startup.⁴⁴ Because the environmental organization comments relied on outdated, generic information about timing, they do not provide a proper basis for the shortened deadline for these specific units. Notably, EPA has not even attempted to provide any explanation of how this shorter deadline is reasonable for White Bluff and Independence in light of site-specific and company-specific considerations. Nor does EPA appear to have required such a short timeframe for the installation of controls in other regional haze plans. Even for AEP’s Flint Creek plant, where SO₂ control equipment *is installed and functioning already*, EPA granted the company 18 months to make any modifications necessary to ensure the controls can meet the BART limit.⁴⁵

b. The 18-month deadline is unreasonable.

The 18-month deadline to install LNB/SOFA at White Bluff and Independence is infeasible, as it does not guarantee sufficient time to develop, plan, permit, install, tune, and test the equipment. Specifically, a project of this scope requires Entergy to develop a prevention of significant deterioration (“PSD”) permit application, obtain a PSD permit, comply with the

³⁸ EAI Comments at 13-14.

⁴⁵ 81 Fed. Reg. at 66,338.

company's internal planning and prudence review procedures, complete a request for proposal ("RFP") process, select a vendor, procure equipment, schedule outages, install equipment, and then tune and test the equipment. Completion of all of these steps will require more than 18 months, even though Entergy already has obtained the necessary PSD permit for White Bluff, and is in the process of developing the PSD permit application for Independence.⁴⁶ Entergy would only be able to complete installation and tuning of LNB/SOFA on all four units by the final deadline if it circumvented its internal planning and prudence review procedures and completed the tuning and testing process *after* the compliance deadline.

The internal process that must be completed before the performance of any equipment work is robust, with preparation for this work just getting underway with respect to Independence. First, projects over \$20 million, like the installation of LNB/SOFA, are subject to an internal company approval process that includes risk review and investment procedures. This process takes approximately two months and requires approval from several levels of Entergy management. Once the review process has been completed, Entergy can undertake project-specific planning. An engineer will draft project specifications based on the Final FIP requirements and design characteristics, a process that takes approximately two months. These specifications will be included in an RFP, which will be put out for a four- to six-week bidding process. Once a vendor is selected, negotiation of the final contract will take an additional four to six weeks.

Simultaneous to this internal process, Entergy must prepare a PSD permit application for the installation of LNB/SOFA at Independence.⁴⁷ Despite the fact that work already is proceeding, the earliest the application will be ready for submittal to ADEQ will be mid-December. ADEQ approval is expected to take, at a minimum, between six and eight months, resulting in permit issuance between mid-June and mid-August 2017, but this process could take longer for a variety of reasons outside of Entergy's control. For example, the permitting process could be extended if significant public comments are received on the draft permit that must be addressed by the ADEQ before a final permit can be issued, due to agency resource constraints, or due to an appeal of the final permit to the Arkansas Pollution Control and Ecology Commission, which, absent additional regulatory proceedings, would result in an automatic stay of the permit pending final resolution of the appeal.

Once the permit is issued and the final contract has been signed, the selected vendor must design and fabricate the equipment, which takes approximately eight months. Outages must be scheduled for all four units, each lasting between six and seven weeks. Once installation is complete, each unit will need to undergo four weeks of boiler tuning and two weeks of performance verification testing to demonstrate that the controls are achieving the anticipated NOx reductions. After this, Entergy will have to perform a final phase of fine-tuning and training. During the final phase, which lasts approximately five months, each unit will undergo a three-month procedure review during which the system description is re-written to include the new equipment and components, and the operating procedures are updated. This process cannot

⁴⁶ Although Entergy already has acquired control equipment for one unit at White Bluff, equipment still must be obtained for the second White Bluff unit and both Independence units to comply with the requirements in the Final FIP.

⁴⁷ As noted above, Entergy already has obtained a permit to install LNB/SOFA on White Bluff but does not yet have all the equipment needed to do so.

be truncated as it requires the operators to observe performance during all operating scenarios, including startup, shutdown, and periods of load transition. The staff must then be trained on both the system description and the operating procedures, which typically takes a month. An additional month is needed to validate operating configurations to determine which combinations result in the best load profile. It would be imprudent not to complete the entire training and fine-tuning process prior to the compliance deadline.

Even with a truncated schedule, Entergy cannot reasonably expect to meet the 18-month deadline. At best, Entergy could take the following steps, which increase risk and cost without any guarantee of compliance. It could circumvent its normal internal procedures, including its risk and prudence reviews and its process for obtaining competitive bids from multiple vendors. Entergy would be required to perform a more limited risk and prudence review, would have to forgo a complete bidding process in favor of using a pre-selected vendor that can fabricate and install the equipment as quickly as possible, and may even need to engage this vendor prior to having all regulatory approvals in hand. These internal procedures are in place to attempt to ensure cost recovery, and failure to comply with them puts the company at risk of making investments that the APSC later determines are not in the public interest and therefore not eligible for cost recovery. The schedule also does not allow for any delays associated with the PSD permitting process.

Finally, even with these truncated procedures, and assuming final PSD permit issuance in mid-June to mid-August 2017, the timeframe allowed in the Final FIP is insufficient for Entergy to conduct thorough testing and tuning of the NOx control equipment, where unforeseen issues frequently arise and must be addressed to ensure compliance. For example, it is common during the installation process to discover previously unknown equipment issues that complicate installation or hinder the expected performance of the installed equipment. Installation of controls involves many variables and each unit has unique characteristics, resulting in unpredictable challenges. As an example, small, unforeseen differences in mill performance or coal pulverization could result in problems that must be addressed to ensure the LNB/SOFA equipment performs as expected.

In light of these site-specific considerations, including the mandatory regulatory approval process, EPA should grant reconsideration and revise the 18-month deadline to provide the full three years provided in the Proposed FIP for installation of LNB/SOFA at White Bluff and Independence. This will allow time for Entergy to comply with its internal planning and prudence review procedures, to obtain all required approvals, and ensure that the controls are properly tuned prior to the compliance deadline. At a minimum, EPA should grant reconsideration and provide at least 30 months for the installation of LNB/SOFA at White Bluff and Independence as this is the minimum amount of time Entergy anticipates that the NOx compliance deadline could be met even by truncating its internal procedures and barring any unforeseen issues.

2. EPA must revise the NOx limit and averaging period that apply during periods of low load.

In the Final FIP, EPA unlawfully introduced, for the first time, a NOx emission limit of 671 lb/hr on a rolling 3-hour average that applies when the White Bluff and Independence units are operating at less than 50 percent of their maximum heat input capacity.⁴⁸ In contrast, EPA had proposed an emission limit of 0.15 lb/MMBtu on a 30 boiler-operating-day rolling average that would apply regardless of the capacity at which the units were operating.⁴⁹ Entergy did not have notice of or an opportunity to comment on the significant change in the Final FIP to the limit and averaging period that apply when the units are operating at low loads. Entergy explained in its comments on the Proposed FIP that a higher limit is necessary during periods of low load operation because the LNB/SOFA system is designed to operate primarily in the range of 50-100 percent of unit load, and the vendor would not guarantee that LNB/SOFA could meet a limit of 0.15 lb/MMBtu for operating loads below 50 percent.⁵⁰ While Entergy appreciates EPA's apparent attempt to account for periods of low load in the Final FIP, EPA must reconsider the emission rate and averaging period that apply when the units are operating at less than 50 percent of the maximum heat input capacity.

First, Entergy did not have an opportunity to comment on the new emission limit and averaging period that apply during low load operation. EPA has not explained why either the limit that it established or the shorter averaging period are appropriate for either White Bluff or Independence, given that they were not raised or considered in the Proposed FIP or in Entergy's comments. The final limit and averaging period are not logical outgrowths of the Proposed FIP and they are plainly unlawful, arbitrary and capricious. EPA must grant reconsideration of these elements of the Final FIP.

Second, the new averaging period is unworkable for low load operation and will result in exceedances of the limit. During periods of load transition and, in particular, periods of reduced load, NOx is very sensitive to changing conditions such as air flow, fuel flow, and burner tilt position. When load is being ramped up or down, and mills are put in or out of service, NOx can spike to levels well above typical levels for short periods of time. Within minutes of the excursion, NOx typically will return to and stabilize at the steady state level. With the short 3-hour averaging period, a single 15-minute spike in NOx could result in NOx exceeding the low-load NOx emission limit for a 3-hour period, even if the remaining 165 minutes were below compliance levels.⁵¹ A 30-boiler-operating-day period is necessary to moderate the variations in NOx due to load transition and low load.

Finally, the low-load NOx emission limit, which EPA set at one half the limit proposed by Entergy, also is problematic. It offers no compliance margin, which is necessary to account for increased NOx levels that occur as a function of low load operation, and the unavailability of SOFA when the unit is operated at less than 30 percent of capacity. When load falls below 50 percent, NOx levels increase as a percentage of heat input, trending upwards as load is reduced. This phenomenon is due to the increased levels of excess air that are used to ensure safe boiler

⁴⁸ 81 Fed. Reg. at 66,344, 66,354.

⁴⁹ 80 Fed. Reg. at 18,974, 18,997.

⁵⁰ EAI Comments at 50.

⁵¹ See Memorandum from Foster Wheeler (hereinafter "Foster Wheeler Memo") (attached as Exhibit F).

operation during low loads. During load swings, control systems lead load increases with increases in air flow and follow load decreases with reductions in air flow. This excess air leads to NOx formation from nitrogen-laden air. Not only are NOx emissions generated at a higher rate at low load, but NOx control options are limited during these periods. SOFA is unavailable when the boiler operates below 30 percent capacity, including during startup, because there is insufficient air to support both good combustion and maintain overfire air flow to the boiler. As a result, the SOFA system cannot provide any NOx reduction during these operational periods.

Accordingly, EPA should reconsider the NOx limit and averaging time that applies to periods of low load operation and adopt the limit requested by Entergy in its comments: a rolling 30-boiler operating day average emission rate of 1,342.5 lb NOx/hr at each coal-fired unit at White Bluff and Independence.⁵² At the least, EPA should revise the NOx averaging time to a 30-boiler-operating day period, and the limit to 895 lb/hr.⁵³ This will allow the inevitable NOx variations to be smoothed out over the averaging period, resulting in a limit that is possible to achieve.

IV. REQUEST FOR STAY

A. EPA Should Grant a Stay Pursuant to the CAA and the APA.

Section 307(d)(7)(B) of the CAA authorizes EPA to stay the effectiveness of a rule for up to three months during reconsideration,⁵⁴ which can be extended for additional three-month periods. Additionally, the Administrative Procedure Act (“APA”) authorizes EPA to stay the effectiveness of a rule indefinitely. Under the APA, “[w]hen an agency finds that justice so requires, it may postpone the effective date of action taken by it, pending judicial review.”⁵⁵ EPA has applied this standard to CAA actions.⁵⁶

Unlike a judicial stay, an administrative stay does not require a demonstration of irreparable harm. The APA states:

When an agency finds that justice so requires, it may postpone the effective date of action taken by it, pending judicial review. On such conditions as may be required and to the extent necessary to prevent irreparable injury, the reviewing court . . . may issue all necessary and appropriate process to postpone the effective date of an agency action or to preserve status or rights pending conclusion of the review proceedings.⁵⁷

The APA deliberately contrasts what is required for an administrative stay—“justice so requires”—and a judicial stay—“conditions as may be required” and “irreparable harm.” Similarly, CAA Section 307(d)(7)(B) authorizes an administrative stay, but does not premise that

⁵⁷ 5 U.S.C. § 705. EPA has stayed a rule pursuant to Section 705 even after the rule’s effective date has passed. See *Stay of Federal Water Quality Criteria for Metals*, 60 Fed. Reg. 22,228 (May 4, 1995).

stay on a finding of irreparable injury, noting simply that “[t]he effectiveness of the rule may be stayed during such reconsideration...for a period not to exceed three months.”⁵⁸

EPA should administratively stay the Final FIP’s emission limitations for White Bluff and Independence while it addresses the issues identified above in Entergy’s Petition, and while the Eighth Circuit considers Entergy’s petition for review of the Final FIP. Specifically, Entergy requests that EPA stay 40 C.F.R. §§ 52.173(c)(6)-(8) with respect to White Bluff and §§ 52.173(c)(24)-(26) with respect to Independence. As explained below, a delay in implementation of the FIP would prevent harms to Entergy, with negligible visibility impact, while the Final FIP is reviewed. An administrative stay also would allow ADEQ time to develop its replacement SIP.

B. Justice Requires that EPA Grant a Stay.

1. Compliance with the SO₂ limits would immediately and irreparably harm Entergy, its co-owners, employees, customers, and communities.

To meet the Final FIP’s SO₂ emission limits at White Bluff and Independence, Entergy must make plans for compliance now. Implementation of the Final FIP requires Entergy to make a Hobson’s choice as soon as possible to either (1) permit, design, gain regulatory approval for, construct, install, and tune dry scrubbers on all four units by October 27, 2021, or (2) deactivate the units by that date, eliminate 230 Entergy jobs in rural Arkansas,⁵⁹ dramatically reduce the local tax revenues, and commit to new resources to replace a significant portion of its generating capacity. Either path for compliance with the SO₂ emission limits at White Bluff and Independence is a complex undertaking that must be pursued independently for each unit, and will result in immediate and irreparable harm to Entergy, its co-owners,⁶⁰ and local economies.

To ensure compliance, either path would require Entergy to begin making commitments and significant financial investments in the immediate future and without state agency review of the proposed path. Entergy must pursue both potential paths for as long as there is regulatory uncertainty.⁶¹ Entergy would suffer irreparable harm if it is forced to proceed before EPA acts

⁵⁸ 42 U.S.C. § 7607(d)(7)(B).

⁵⁹ Entergy also directly employs several hundred contractors over the course of the year, for both seasonal outage work and ongoing plant support.

⁶⁰ As described in petitions for reconsideration of the Final FIP filed by co-owners of the White Bluff and Independence plants, the harms to these co-owners would be significant. For example, deactivation of both plants in October of 2021 would create the immediate need to add an estimated 500 megawatts (“MW”) of firm generation capacity to the Midcontinent Independent System Operator (“MISO”) side of the Arkansas Electric Cooperative Corporation (“AECC”) system. This replacement capacity is estimated to require the investment of \$490,000,000. The levelized investment recovery cost of this generation capacity to AECC’s member cooperatives would be approximately \$34,000,000 annually. Jonesboro City Water and Light estimates that replacement of its share of ownership of the generation capacity of the White Bluff and Independence units in 2021 would result in increased costs between \$16.3 million and \$25 million, *in 2021 alone*, which translates to a 17-27 percent increase in customer rates. See Petition for Reconsideration and Request for Administrative Stay of AECC and Petition for Reconsideration and Request for Administrative Stay of Energy & Environmental Alliance of Arkansas (“EEAA”).

⁶¹ Either choice would cause irreparable harm in so far as significant financial investments would need to be made that could not be reversed if the Final FIP were later revised or vacated. Additionally, due to the lead time needed to install FGD technology or to prepare for permanent retirement, more time is needed to select one of these two options than the Final FIP allows. As described in this section, regulatory reviews are required for both paths, so the

on the Petition and before the Eighth Circuit determines the merits of Entergy's petition for review of the Final FIP. And yet, to meet the compliance deadline, it will be compelled to do so or risk noncompliance with the Final FIP. The first path, installing dry scrubbers on all four units, would be a massive undertaking costing approximately \$2 billion. The first phase of this multi-phase project would have to begin as soon as the decision to proceed was made, as the process would require the entirety of the five years allotted in the Final FIP, as explained in further detail below, including spending over \$150 million in the first 18 months alone. The second path, deactivating the units, is complicated and costly in different ways, as explained below. Both paths cause Entergy irreparable harm.

Given the lead times for either path, Entergy must start immediately to conduct analyses and reviews to support its internal decision-making process, which will take several months. Entergy's internal review process would assess both approaches, particularly analyzing and comparing the economics of each approach, and would be coordinated with the co-owners of White Bluff and Independence. Assessing the costs of the two approaches is extremely complicated. For example, for EAI to retire an existing generating unit, EAI must provide at least six months' notice to MISO, the regional transmission operator that dispatches White Bluff and Independence, of its intent to retire the unit. Because of the interconnected nature of the electric grid, a decision to retire a unit can have implications for the remainder of the grid, some of which may require upgrades to the transmission system to ensure that the grid can be operated reliably after the generating unit is retired. Accordingly, owners/operators of a generating unit typically would request that MISO perform an "Attachment Y-2 study," which would determine, on a non-binding basis, whether the retirement of the generating unit (i.e., White Bluff or Independence) would impact transmission system reliability, or whether the plant would need to continue to operate until transmission upgrades or other system changes to maintain reliability can be completed. In Entergy's experience, an Attachment Y-2 study takes approximately three to four months for a standard request. However, this situation is far from standard; assessing the retirement of four units totaling nearly 3400 MW of capacity may take much longer. Entergy would incorporate the Attachment Y-2 results into its internal economic analysis. Depending on the time needed to perform the economic analysis, coordinate with co-owners, and obtain the results of MISO's Attachment Y-2 study, this decision-making process would take between six and nine months.

Compliance with the FIP also requires EAI, the operator of all four units, along with the other co-owners of White Bluff and Independence to adhere to other regulatory processes, each unique to each co-owner.⁶² In similar cases involving significant capital investments at existing generating units, EAI has sought a declaratory order from the APSC confirming that the selected path is in the public interest.⁶³ Because EAI is a rate-regulated entity, costs prudently incurred in the provision of electrical service typically are recoverable from customers, but cost recovery can occur only after the costs are reviewed by the APSC and a regulatory rate adjustment is made. In

compressed timeline mandated by the Final FIP requires Entergy to simultaneously prepare for both paths in the event that the selected path does not earn regulatory approval.

⁶² For example, EMI also has regulatory reviews and approvals before the Mississippi Public Service Commission that it must pursue. *See also* Petition for Reconsideration and Request for Stay of Energy and Environmental Alliance of Arkansas.

⁶³ *See, e.g.*, APSC Docket No. 09-024-U (Seeking public interest finding for installation of environmental controls at White Bluff Units 1 and 2).

other words, a public interest finding addresses the prudence of the investment; it does not address the prudence of the management of the incurrence of the costs nor does it modify base rates or effect other charges to include those costs (which would be the result of a separate review by the APSC in a later proceeding). If cost recovery is not approved or if recovery is significantly delayed, EAI could be deprived of a reasonable opportunity to receive adequate recovery of costs incurred.⁶⁴ In either case, the preparation of the application and supporting testimony could take up to six months. Additionally, completion of discovery, an APSC-determined procedural schedule with multiple rounds of testimony from the APSC General Staff, Attorney General, and other intervenors, a public hearing, and the issuance of a final order, could take an additional 14 months to complete. Accordingly, the state regulatory process may take as long as 20 months, and that is prior to any potential challenge by EAI to the APSC's final order, which could include a petition for rehearing and subsequent appeal.

Should Entergy choose to install dry scrubbers on all four units, Entergy would be forced to make considerable expenditures within the next few years, effectively prohibiting any alternative approach. Of the approximately \$2 billion that Entergy estimates it would spend for scrubbers on White Bluff and Independence, Entergy would need to spend well in excess of \$38 million within the first year, \$150 million within 18 months, and \$305 million within 24 months.⁶⁵

The work to install the dry scrubbers also would need to begin immediately to comply with the FIP's five-year deadline. During the preliminary engineering phase of the project, which is expected to take between six and 12 months, an engineer would need to develop detailed specification requirements for the engineering, procurement, and construction of the FGD systems. Contractors would need at least three months to develop proposals, and then several weeks would be required to evaluate the proposals and award the contract. Because White Bluff and Independence have different co-owners, two separate FGD contracts would need to be developed. Afterward, the FGD contractor at each plant would proceed with the detailed engineering phase, during which every component required for a complete and operable FGD system would be designed and fabricated. Next, the engineered components would be delivered to the sites and the FGD contractor at each site would erect them and integrate them into the existing plants. A tie-in outage must be taken for each unit so that physical connections to existing systems can be made. Because Entergy would not take simultaneous outages at all four units for reliability reasons, and because there would be two FGD contracts awarded at different times, the construction phase likely would be staggered by approximately one year across all four units. Once constructed, equipment startup and commissioning would occur, followed by operational tuning and performance optimization. Performance testing would then

⁶⁴ EAI has elected to be regulated pursuant to Ark. Code Ann. § 23-4-1201 et seq., which provides that a public utility may choose to be regulated under a formula rate review mechanism that provides for an annual streamlined review of a public utility's rates and designation of a test period based on a projected test year. EAI's APSC-approved Rate Schedule No. 44, Formula Rate Plan Rider ("Rider FRP") provides for annual adjustment of customers' rates based on a comparison of EAI's earned return on common equity and its target return rate approved by the APSC. However, pursuant to Ark. Code Ann. § 23-4-1207 and Rider FRP, the annual Rider FRP revenue increase or decrease for each rate class shall not exceed four percent of each rate class' revenue. Accordingly, in complying with the FIP, EAI may pursue cost recovery for those costs pursuant to Rider FRP or other potential cost recovery mechanisms.

⁶⁵ These estimates were developed by Sargent & Lundy but do not include the significant costs for AFUDC, escalation and owner's costs that Entergy also will incur. Sargent & Lundy Memo at 5.

be conducted to confirm compliance with emission limits. The FGD contractor would need approximately three years to complete engineering and construction of one unit, followed by up to six months of commissioning, startup, performance optimization, and performance testing.

Alternatively, were Entergy to choose deactivation, the company would have to secure additional regulatory approvals as quickly as possible to provide for a smooth transition to replacement power by the 2021 deadline. The company must provide six months' notice to MISO before a generator can be retired (the "Attachment Y" process described above).

Entergy next would need to procure and build replacement power because White Bluff and Independence currently are needed for Entergy to provide reliable electricity generation to its customers and meet its obligations to MISO. Entergy's resource planning process would consist of designing, gaining regulatory approval for, constructing, and making operational a new alternative generating unit. Entergy anticipates that the replacement generation would be a combined cycle gas turbine ("CCGT"),⁶⁶ which may require construction of a new gas pipeline to the selected site. Depending on the site that is selected for the CCGT, rights-of-way may need to be obtained. Transmission would need to be planned and built to connect the new CCGT with the grid. To construct replacement generation as quickly as possible, Entergy must prepare an environmental permit application, prepare RFPs for the construction, select a vendor, and submit a permit application. The time required for this process means that replacement power would not be available for five years at the earliest, thus exposing customers to market capacity prices in the interim. Accordingly, planning must begin immediately to limit, as much as possible, the duration of customer exposure to market prices. In the meantime, even maintaining reliability through the purchase of power would require Entergy to accelerate planned transmission projects. A project that currently is planned to be completed in 2024 would have to be accelerated to be completed in 2020, at an additional cost of \$8 million and with a start date in 2017.

Ceasing operations at White Bluff and/or Independence would cause irreparable harm to Entergy employees and the communities in which they work. The total number of jobs created and supported by the White Bluff plant alone is estimated to be 1,237.⁶⁷ Entergy itself employs 105 full-time employees at White Bluff, along with 10 Entergy Service Company employees that support White Bluff full time. White Bluff also employs approximately 300 contractors for at least six weeks in the spring and fall each year for planned outage support. Additionally, there are about 20 contractors that work full time in security, coal dust management, janitorial, lawn maintenance, ash management and scaffolding support. At Independence, Entergy employs 108

⁶⁶ White Bluff cannot be replaced by renewable energy. White Bluff provides approximately 1,600 MW of reliable capacity to the MISO system and there are no practical or reasonable renewable generation options to meet the MISO resource adequacy requirements currently satisfied by White Bluff. Replacement of White Bluff would require 3,200 MW of solar power (necessitating 22,000 acres of panels), or 10,000 MW of wind generation (necessitating 7,000 windmills that would have to be located in the plains states hundreds of miles away from Entergy's load). Additionally, there is insufficient biomass fuel available to supply a 1,600 MW replacement biomass plant, and even if sufficient fuel were available, it would take an impracticable amount of trucks to deliver the necessary fuel. None of these options is feasible.

⁶⁷ Willie Lee Brooks, Jr., Senior Analyst, Economic & Financial Risk, *What is the Economic Impact of the White Bluff Electric Power Plant?*, at 2, Arkansas Electric Cooperative Corporation (May 30, 2014), available at <http://www.arkleg.state.ar.us/assembly/2015/Meeting%20Attachments/890/112666/HANDOUT%20%20-%20HIGHLEY%20%20Economic%20Impact%20of%20White%20Bluff%20Electric%20Pwr%20Plant.pdf>.

full-time employees, along with seven Entergy Service Company employees that support Independence full time. Independence also employs 83 contractors, who provide janitorial services, maintenance support, ash disposal services, and work on insulation and scaffolding during outages. If White Bluff and Independence were to cease operations, the company would have to lay off or reassign its employees, and the contractors would be out of work. These shutdowns would have significant impacts on the rural Arkansas communities where the plants are located. For example, the estimated the value of White Bluff to the local economy is \$173 million.⁶⁸

2. Compliance with the NOx limits would immediately and irreparably harm Entergy, its co-owners, employees, customers, and communities.

As explained above in Section III.D, the 18-month deadline to install LNB/SOFA at White Bluff and Independence is infeasible, as it does not provide sufficient time to develop, plan, permit, install, and appropriately tune the equipment. Entergy could complete installation of LNB/SOFA at all four units by the final deadline only by circumventing its normal internal procedures and the tuning and training process. Entergy would be forced to perform a more limited risk and prudence review, would have to forgo a competitive bidding process in favor of using a pre-selected vendor for fabrication and installation, and may even need to engage this vendor prior to having all regulatory approvals in hand. These procedures are in place to attempt to ensure cost recovery, and failure to comply with them puts the company at risk of making investments that the APSC later determines are not in the public interest and therefore ineligible for cost recovery. Additionally, Entergy would be forced to comply with the emission limits prior to the conclusion of its tuning and training procedures. Even with these truncated procedures, the schedule does not allow for any unforeseen issues in the installation and tuning process, which frequently arise and complicate installation or hinder the expected performance of the installed equipment.

Implementation of the Final FIP forces Entergy to choose between two untenable options – each resulting in irreparable harm and unnecessary risk: (1) increasing costs and risk through rushed work and non-compliance with company prudence procedures, with no guarantee of FIP compliance once the work is completed, and (2) taking more time than the Final FIP permits, resulting in cessation of operation of the White Bluff and Independence units until LNB/SOFA can be installed. Beyond the fact that cessation of operations would necessitate Entergy to obtain costly replacement power on the open market, critically, it also could cause reliability issues, as generation from White Bluff and Independence is necessary for Entergy to provide reliable electricity generation to its customers and meet its obligations to MISO. In light of this, EPA must issue a stay of the deadline for compliance with the NOx limits until a more appropriate deadline can be set.

⁶⁸ *Id.*

3. A stay would prevent harm to Entergy and its co-owners, customers, and communities but would still allow Arkansas to meet its regional haze goals.

Arkansas already is below the URP and EPA's RPGs, and thus a delay in the implementation of the FIP would not contribute to unacceptable visibility impairment. As discussed previously, the IMPROVE data for January 2014 through December 2015 show that visibility continues to improve at a greater rate than the URP in Caney Creek and Upper Buffalo.⁶⁹ The recent IMPROVE data also confirm that visibility in the two Arkansas Class I areas already is better than EPA's final RPGs for the areas.⁷⁰ Accordingly, a stay would not interfere with attainment of the URP or the RPGs.

D. Entergy Also Meets the Four Factors that Courts Consider When Assessing Judicial Stay Requests.

Although the judicial test for analyzing a request for a stay does not apply here, Entergy's request for stay nonetheless satisfies this test. First, as described above, Entergy has made a strong showing of likelihood of success on the merits. For the reasons explained in this Petition, the Final FIP contains significant errors and unreasonable requirements upon which Entergy was unable to comment during the period for public review, and that are not logical outgrowths of the Proposed FIP. The CAA *requires* that EPA reconsider these elements of the Final FIP. Second, Entergy would be irreparably harmed if the Final FIP is not stayed. As explained above, implementation of the FIP would force Entergy to make expensive choices about the installation of controls and possible deactivation of units in very short order. Entergy would be forced to spend significant amounts of money once these choices are made. Third, a stay of the rule would not cause harm. Visibility in Arkansas' Class I areas already is improving at a rate greater than the URP for each area, and the areas already have surpassed EPA's final RPGs for the first planning period. Implementation of SO₂ and NO_x controls at White Bluff and Independence is not needed to achieve either the URP or the RPGs. Fourth, the balance of harms and the public interest favor a stay. A stay would prevent significant, irreparable harm to Entergy with little visibility impact, as Arkansas already has met the goals that the installation of FGD and LNB/SOFA are designed to achieve. It also would prevent the harm to employees and local communities that would ensue from the deactivation of any of the units. In light of this, a stay is appropriate and just, and should be granted.

V. CONCLUSION

For the reasons discussed above, Entergy urges EPA, by February 1, 2017, to reconsider and stay certain provisions of the Final FIP to avoid the harms to Entergy, its employees, co-owners, customers and local communities, as described herein.

EHS solutions delivered uncommonly well

TABLE OF CONTENTS

1. EXECUTIVE SUMMARY 1-1

2. EMISSIONS REDUCTIONS DUE TO PLANT CLOSURES 2-1

3. VISIBILITY IMPROVEMENTS DUE TO PLANT CLOSURES 3-1

1. EXECUTIVE SUMMARY

This report presents the emissions reductions and visibility improvements attributed to the closures of coal-fired power plants located in the states of Texas and Tennessee. The impacts of these planned closures on the short term (i.e., first planning period) and the long-term visibility improvement at the Arkansas Class I areas is important for the Arkansas Department of Environmental Quality (ADEQ) to consider in its development of a Regional Haze State Implementation Plan (SIP) to address emissions of sulfur dioxide (SO₂) for the first planning period.

The completed and/or planned shutdown of five (5) coal-fired power plants¹: will result in emissions reductions of greater than 206,000 tons per year (tpy) of SO₂ and more than 39,000 tpy of nitrogen oxides (NO_x). These massive emissions reductions are predicted to improve visibility conditions in Arkansas Class I areas, which, as documented in Trinity reports submitted under separate cover, are already substantially better than the reasonable progress goals set for the first planning period.

Based on the emissions reductions and anticipated visibility improvements from these coal-fired power plant closures, it is clear that no additional reductions are *necessary* at this time to achieve reasonable progress towards the goals of the Regional Haze Program. ADEQ should consider these reductions and the resulting visibility improvements at the Arkansas Class I areas in their first planning period SIP development as well as the long-term strategy development.

¹ These plants are Luminants' Big Brown, Sandow, and Monticello plants; CPS Energy's Deely plant; and Tennessee Valley Authority's Allen plant.

2. EMISSIONS REDUCTIONS DUE TO PLANT CLOSURES

Luminant Energy recently announced that it will be closing three (3) coal-fired power plants in 2018: The Big Brown Plant southeast of Corsicana, Texas, the Sandow Plant northeast of Austin, Texas, and the Monticello Plant near Mount Pleasant, Texas.² One other Texas coal-fired power plant – CPS Energy’s Deely plant located in east Texas – is also scheduled to close in 2018.³ In addition, Tennessee Valley Authority (TVA) has announced that it will be retiring the Allen coal-fired plant in 2018.⁴

Table 2-1 summarizes the maximum annual SO₂ and NO_x emissions for each of these plants. The emissions for the Texas plants were obtained from a review of the Technical Support Document⁵ (baseline modeling scenario) for EPA’s 2014 Texas Regional Haze Reasonable Progress Federal Implementation Plan (2014 TX RP FIP), and, according to the FIP, represent the maximum annual emissions from 2008-2012. The emissions for TVA’s Allen Plant were obtained from the Clean Air Markets Database (CAMD); the maximum annual emissions for 2008-2012 are used for consistency.

Table 2-1. Summary of Maximum Annual Emissions for To-Be-Closed Plants

Facility Name	SO₂ (tpy)	NO_x (tpy)
Big Brown	66,227.29	6,752.83
Sandow 5	2,152.60	1,397.57
Sandow Steam	25,594.22	1,500.37
Monticello	73,212.41	11,433.76
Deely	26,588.75	9,933.45
Allen	12,495.02	8,056.72
TOTAL	206,270.29	39,074.70

As presented in Table 2-1, more than 206,000 tpy of SO₂ and 39,000 tpy of NO_x reductions will take place within the first planning period, which ends on December 31, 2018. These total reductions of SO₂ and NO_x are significantly higher than the emissions reductions anticipated by the final Arkansas Federal Implementation Plan (FIP)⁶ or the proposed Arkansas SIPs (including both the final and approved NO_x-related SIP revision and

TX166-010-09 Memo_TXHAZE_2018CAMx 16Sept13

The modeled emission rates are similar to, but do not exactly match in every case, the information available from CAMD for 2008 to 2012, Accessed January 2018.

⁶ 81 Fed. Reg. 66,332 (September 27, 2016).

the proposed SO₂-related SIP revision). They are also greater than the maximum emissions for Entergy Arkansas, Inc.'s (EAI) White Bluff and Independence facilities combined. Moreover, the emissions reductions from the plant closures are taking place within the first planning period, as compared to the SO₂ reductions stipulated by the Arkansas FIP or proposed Arkansas SIP.⁷

In addition to the emissions reductions, the relative distances for the plants (especially Monticello, Big Brown, and Allen) to the Arkansas Class I areas are comparable to the EAI plants; therefore, predicted visibility improvements at the Arkansas Class I areas would also be comparable. Section 3 provides a discussion of potential visibility improvements due to the plant closures.

⁷ Under the FIP, the deadline for White Bluff and Independence to comply with the SO₂ limitations is October 27, 2021. ADEQ's proposed SIP would require compliance with the SO₂ limitations by approximately the end of 2021 - three years after EPA's final action on the SIP, which is projected to be the end of 2018. *See* Memorandum of Understanding between EPA and ADEQ (Dec. 14, 2017).

3. VISIBILITY IMPROVEMENTS DUE TO PLANT CLOSURES

Figure 3-1 shows the locations of the to-be-closed plants relative to the two (2) Arkansas Class I areas: Caney Creek Wilderness Area (CACR) and Upper Buffalo Wilderness Area (UPBU). Table 3-1 provides the distances to CACR and UPBU from each plant.

Figure 3-1. Locations of To-Be-Closed Plants with respect to the Arkansas Class I Areas

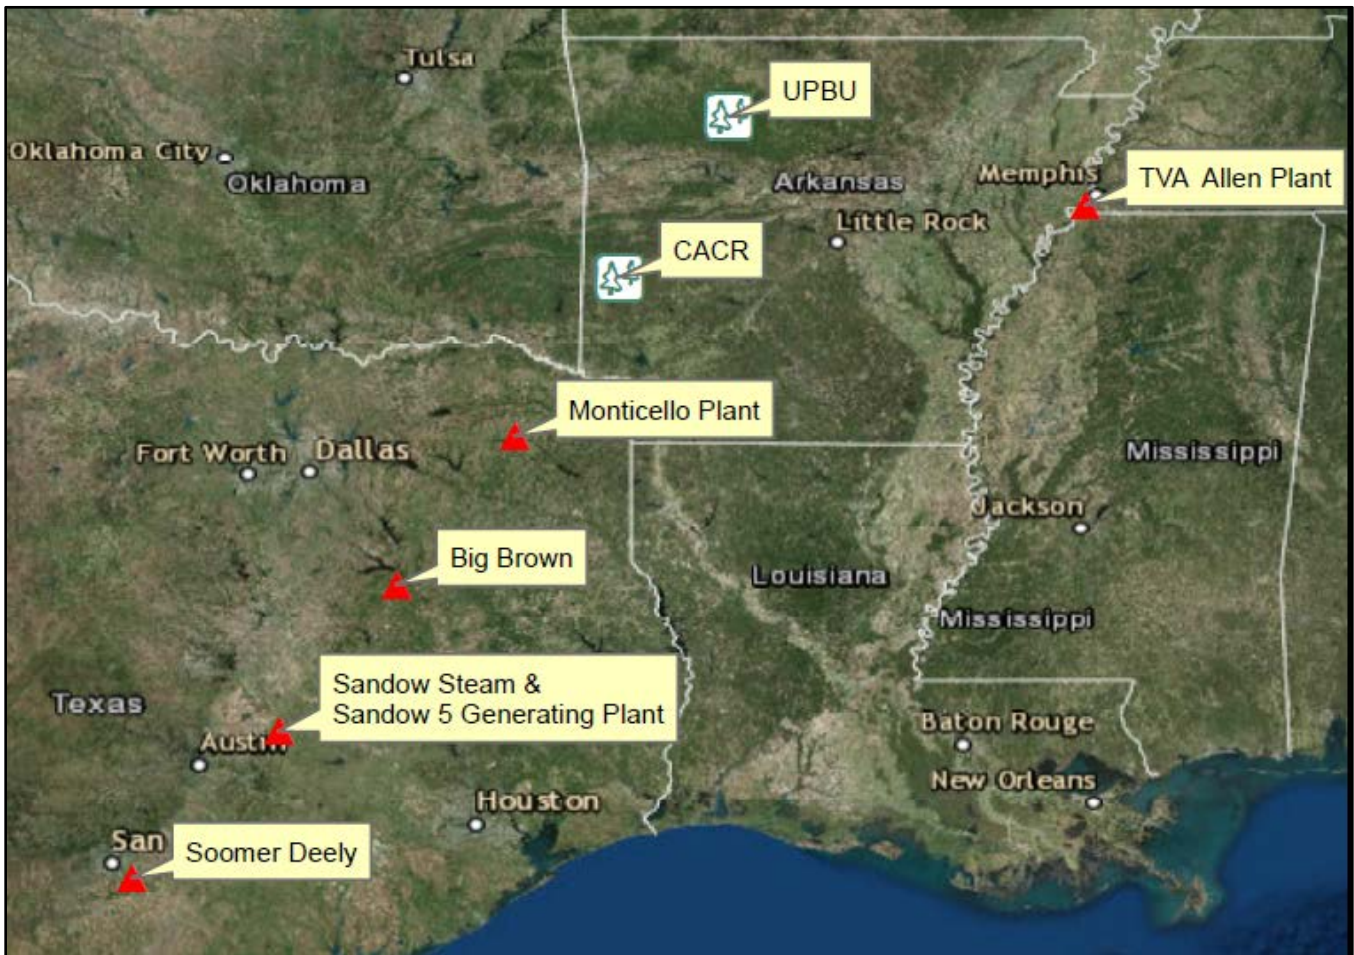

Table 3-1. Distance from To-Be-Closed Plants to Class I Areas

Facility Name	Distance to CACR (km)	Distance to UPBU (km)
Big Brown	343	517
Sandow 5 Generating Plant	512	686
Sandow Steam Plant	512	686
Monticello	172	347
Deely	697	870
Allen	370	288

The four coal-fired power plants in Texas that will be closed are among the 38 power plants included in EPA’s regional haze modeling for the 2014 TX RP FIP,⁸ and the visibility impacts attributable to these plants can be determined from that modeling. Table 3-2 presents the worst 20 percent days average visibility impact, in delta deciview (Δdv), and the individual contribution to total visibility extinction, in percent, at CACR and UPBU attributable to each of the plants.

Table 3-2. Worst 20% Visibility Impact (Δdv) and Contribution to Total Extinction for the To-Be-Closed Texas Plants

Facility Name	Worst 20% Days Average (Δdv)		Contribution to Total Extinction (%)	
	CACR	UPBU	CACR	UPBU
Big Brown	0.0564	0.0225	0.63%	0.25%
Sandow 5 Generating Plant	0.0011	0.0010	0.01%	0.01%
Sandow Steam Plant	0.0042	0.0041	0.05%	0.05%
Monticello	0.1594	0.0401	1.76%	0.45%
Deely	0.0021	0.0031	0.02%	0.03%

As shown in Table 3-2, the planned shutdown of the Texas plants (not accounting for TVA’s Allen plant) in the first planning period is predicted by EPA’s modeling to result in a total reduction of approximately 2.5 percent in visibility extinction at CACR and about 0.8 percent at UPBU.

The reduction at CACR is nearly equivalent to the total contribution to visibility extinction from all point sources in Arkansas, and is equivalent to one-fifth of the total impact at CACR from all sources in Arkansas.⁹ In other words, the improvement at CACR predicted by the shutdown of the Texas plants would be equivalent to closing one-fifth of all emissions sources (including stationary and mobile) in the entire state of Arkansas.

The predicted significance of the Texas plant closures is illustrated in Figure 3-2 and Figure 3-3, which present the glidepaths for CACR and UPBU along with observed IMPROVE haze indices for 2002 through 2016 and predicted 2018 values calculated by subtracting the cumulative contribution to total extinction from the four Texas plants from the 2016 observed haze index. These are conservative estimates of 2018 predicted visibility impairments as they do not take into account any other reductions taking place, e.g., at TVA’s Allen plant and others.

⁸ EPA’s 2014 modeling was completed using the Comprehensive Air Quality Model with Extensions (CAMx), the Modeled Attainment Test Software (MATS) post-processor, which tethers the model-predicted values to actual monitoring data via Relative Response Factors (RRFs), and the Particulate Source Apportionment Tool (PSAT), which was developed to determine source-specific contributions based on the data provided by CAMx. The modeling was completed by a contractor: Ramboll (formerly ENVIRON).

⁹ Based on EPA’s modeling, the contribution to predicted extinction at CACR from point sources in Arkansas is 2.87 percent, and the total contribution from the entire state of Arkansas (all sources including stationary and mobile) is 13.10 percent.

Figure 3-2. CACR Glidepath with Observed and 2018 Predicted Haze Index

Figure 3-3. UPBU Glidepath with Observed and 2018 Predicted Haze Index

The visibility improvements due to the Texas plant shutdowns are predicted to further reduce visibility impairment in CACR and UPBU, increasing the already significant gap between the observed haze indices and the glidepaths. Furthermore, because the shutdowns will occur before the end of 2018, the visibility improvement will take place before the end of the first planning period. Table 3-3 provides a comparison of 2016 observed haze indices, 2018 predicted haze indices, and the FIP's 2018 Reasonable Progress Goals.

Table 3-3. Comparison of Observed 2016 and Predicted 2018 Haze Index with 2018 and 2028 RPG

Class I Area	Observed 20% Worst Days Average for 2016	Predicted 20% Worst Days Average for 2018	RPG for 2018
CACR	19.35	18.87	22.47
UPBU	19.33	19.18	22.51

Attachment A – Cost-Effectiveness Calculation

EXECUTIVE SUMMARY

On April 8, 2015, the U.S. Environmental Protection Agency (EPA) published in the *Federal Register* a proposed rule that would partially approve and partially disapprove specific portions of the Arkansas State Implementation Plan (AR SIP) and issue a Federal Implementation Plan (FIP) that would regulate a group of Arkansas electric generating units (EGUs).¹ In this rule, EPA proposes to require additional SO₂ emission reductions that would require retrofitting new FGD systems on Entergy's White Bluff Station Units 1 and 2 and Entergy's Independence Station Units 1 and 2.

Sargent & Lundy (S&L) was contracted by Entergy to review EPA's proposed cost modifications as described in its Technical Support Document entitled, "Technical Support Document for EPA's Proposed Action on the Arkansas Regional Haze Federal Implementation Plan," hereinafter referred to as "FIP TSD," including one of its appendices, entitled "Appendix A. Technical Support Document for the SDA Control Cost Analysis for the Entergy White Bluff and Independence Facilities Arkansas Regional Haze Federal Implementation Plan (SO₂ Cost TSD)," hereinafter referred to as "Cost TSD."

Cost-effectiveness is influenced by two variables: the total annualized cost to retrofit dry FGD systems (\$/yr) and the corresponding reduction in annual SO₂ emissions (tons per year "tpy"). EPA's approach does not accurately calculate either variable.

Based on our review, the following items in EPA's analysis were identified to result in overstating the tons of SO₂ removed:

- After defining a baseline SO₂ emission period of between 2009 and 2013, EPA arbitrarily excluded the years with the maximum and minimum annual averages;
- When calculating SO₂ emission reductions due to FGD retrofits, EPA incorrectly used maximum monthly averages for baseline SO₂ emissions; and
- A controlled SO₂ limit of 0.06 lb/MMBtu is not a realistic or sustainable value to maintain on a long-term basis when considering the normal variation in operation that occurs at all coal-fueled facilities.

In addition, the following items in EPA's analysis were identified to result in understating the annualized cost of the dry FGD retrofit:

- EPA subtracted over \$23 million in BOP costs for both units because they mistakenly believed the equipment to be included in Alstom's scope;
- Because EPA mistakenly removed BOP cost items that should be included in the estimate, they over-estimated and misapplied percent reductions to other cost items, resulting in cost subtractions of over \$7 million for both units;

¹ See 80 Fed. Reg. 18,944 (April 8, 2015).

- EPA removed over \$41 million per unit in Owner's Costs despite the fact that these are real costs that the Entergy will incur;
- EPA under-estimated cost escalation, and in some cases de-escalated costs, by relying on cost indices rather than using vendor pricing information, all of which resulted in under-estimating costs by more than \$42 million per unit;
- EPA incorrectly utilized the IPM model, which is not designed to evaluate site-specific costs, to verify O&M costs at White Bluff;
- EPA scaled capital costs to a design fuel of 0.68 lb/MMBtu, which when compared to operating data, is completely insufficient to ensure compliance with the proposed emission limits for nearly half of the time;
- While we agree that O&M costs should be based on 0.68 lb/MMBtu, EPA's methodology to scale direct O&M costs based on fuel sulfur levels is incorrect and resulted in under-estimating these costs by over \$5 million per unit;
- EPA incorrectly scaled indirect O&M costs using fuel sulfur levels, despite these costs being estimated as percentages of capital cost, which resulted in under-estimating these costs by over \$4 million; and
- EPA used a remaining useful life of 30 years, when Entergy is proposing to cease coal-fired operations on these units in 2027 and 2028, resulting in a remaining useful life of 6 or 7 years.

As discussed above, S&L's analysis reveals that EPA overstates the cost-effectiveness (\$/ton of SO₂ removed) to retrofit dry FGD systems at White Bluff Units 1 and 2, which EPA proposes to require in its FIP. In its approach, EPA understated the annualized cost of the control systems and overstated the tons of SO₂ that would be removed by its FIP-imposed FGD retrofits. To better address EPA's questions on scope and cost items which it did not understand, S&L has prepared an updated cost report to clarify and provide further detail around scope items and cost items included in the estimate.² The corrected and updated cost-effectiveness for both White Bluff units is greater than \$7500/ton, which is clearly not cost effective.

With respect to EPA's Reasonable Progress Goal (RPG) analysis for SO₂ controls, EPA did not follow its own guidance document when conducting its four factor analysis of Independence. EPA failed to consider lower cost options that could reduce SO₂ emissions at Independence and instead concluded that BART-level controls were required to meet RPG. EPA did not prepare cost estimates based on design parameters for FGD systems retrofit at Independence, as required by their RPG guidance document. EPA did not conduct a dollar-per-deciview analysis, as recommended in its RPG document for these analyses to demonstrate the benefit of retrofitting dry FGD at Independence accounting for visibility benefits. When applying annualized costs to projected visibility improvements the result is over \$1.3 billion/ Δ dv for Caney Creek and over \$1.5 billion/ Δ dv for Upper Buffalo, which is clearly not cost effective.

² See S&L Report #012831 ("White Bluff Dry FGD Cost Estimate and Technical Basis") (July 2015).

1. INTRODUCTION

On April 8, 2015, the U.S. Environmental Protection Agency (EPA) published in the *Federal Register* a proposed rule that would partially approve and partially disapprove specific portions of the Arkansas State Implementation Plan (AR SIP) and issue a Federal Implementation Plan (FIP) that would regulate a group of Arkansas electric generating units (EGUs).³ In this rule, EPA proposes to require additional SO₂ emission reductions that would require retrofitting new FGD systems on Entergy's White Bluff Station Units 1 and 2 and Entergy's Independence Station Units 1 and 2.

Sargent & Lundy (S&L) was contracted by Entergy to review EPA's proposed cost modifications as described in its Technical Support Document entitled, "Technical Support Document for EPA's Proposed Action on the Arkansas Regional Haze Federal Implementation Plan," hereinafter referred to as "FIP TSD," including one if its appendices, entitled "Appendix A. Technical Support Document for the SDA Control Cost Analysis for the Entergy White Bluff and Independence Facilities Arkansas Regional Haze Federal Implementation Plant (SO₂ Cost TSD)," hereinafter referred to as "Cost TSD."

S&L's experience in the electric power industry, as well as our experience with the Entergy facilities makes us uniquely qualified to perform this review. S&L has considerable experience with the federal and state environmental regulations affecting power plant operations, as well as the specification, evaluation, selection, and implementation of emission control technologies for both gas- and coal-fueled utility power facilities, including extensive experience with various FGD technologies. For example, since 2000, S&L has provided, or is currently providing, engineering services for the implementation of over 40 wet FGD projects, 30 dry FGD projects, and 25 dry sorbent injection (DSI) projects, all of which are technologies that are used to control SO₂ emissions. Our first-hand experience with these technologies provides us with a thorough understanding of both capital and operating and maintenance (O&M) costs associated with these technologies, as well as providing us with a comprehensive understanding of the achievable emission rates and limitations of these technologies.

S&L's analysis reveals that EPA overstates the cost-effectiveness (\$/ton of SO₂ removed) to retrofit dry FGD systems at White Bluff Units 1 and 2, which EPA proposes to require in its FIP. Cost-effectiveness is influenced by two variables: the total annualized cost of retrofit dry FGD systems (\$/yr) and the corresponding reduction in annual SO₂ emissions (tons per year "tpy"). EPA's approach does not accurately calculate either variable. In its approach, EPA understated the annualized cost of the control systems and overstated the tons of SO₂ that would be removed by its FIP-imposed FGD retrofits.

³ See 80 Fed. Reg. 18,944 (April 8, 2015).

2. Comments to the FIP TSD – SO₂ Emission Reduction Errors

The majority of S&L's comments are relative to EPA's Cost TSD; however, we note that in its FIP TSD, EPA incorrectly estimates both baseline emissions and SO₂ emission reductions that would result from the retrofit of dry FGD systems at White Bluff station. In addition, in proposing emission rates for White Bluff station, EPA proposed SO₂ emission limits that are consistent with performance guarantees offered by dry FGD suppliers during initial performance testing, not emission rates that are achievable over the 30-year life EPA assumed in its analysis. The following sections describe EPA's flawed analysis contained in the FIP TSD.

2.1 Baseline Emission Rates

Although baseline emission rates identified in Entergy's original BART analysis⁴ were calculated based on the average annual emission rates from 2001 to 2003, in the FIP TSD, EPA redefines baseline emission by using a 3-year average of annual average SO₂ emissions from the years 2009 to 2013, excluding the years with the maximum and minimum annual averages.⁵

We can find no reason to reject EPA's selection of 2009 to 2013 as the baseline period as it represents more recent operation. However, the approach used by EPA to exclude the maximum and minimum values is entirely arbitrary and EPA does not explain how this approach represents a more realistic depiction of anticipated emissions from the existing sources.

The BART Guidelines state that baseline emissions from existing sources "should represent a realistic depiction of anticipated annual emissions for the source."⁶ In general, for the existing sources, facilities should estimate the anticipated annual emissions based upon actual emissions from a baseline period.⁷ However, EPA provides no explanation or analysis to demonstrate that the approach taken results in a realistic depiction of anticipated annual emissions from White Bluff and Independence. In addition, there is no basis for concluding that EPA's approach of excluding actual emissions data more accurately represents the actual operation of the units. Finally, to our knowledge, with the exception of EPA's proposed Texas FIP, this approach has not been used previously by EPA as a methodology for evaluating baseline emissions in other evaluations (and even if EPA had done so, it is not justified here).

The following table shows a comparison between the baseline emissions as established using EPA's approach and baseline emissions calculated as a straight average for various timeframes within the 2009-2013 period.

⁴ Revised Bart Five Factor Analysis, White Bluff Steam Electric Station, Redfield, Arkansas, October 2013, Trinity Consultants.

⁵ See EPA-R06-OAR-2015-0189-0093-White Bluff_R6 cost revisions2.xlsx, under Annual Emissions.

⁶ 40 CFR Part 51 Appendix Y.

⁷ *Id.*

Table 1: Comparison of Baseline SO₂ Emissions for White Bluff and Independence

Unit	EPA Approach 3 Year Average* (tons)	3 Year Average 2009-2011 (tons)	3 Year Average 2010-2012 (tons)	3 Year Average 2011-2013 (tons)	5 Year Average 2009-2013 (tons)
White Bluff 1	15,816	15,745	15,395	15,826	15,939
White Bluff 2	16,697	15,582	15,217	16,697	16,034
Independence 1	14,269	14,160	15,486	14,707	14,258
Independence 2	15,511	14,673	15,196	16,035	15,407

*EPA's approach includes 2009-2013 3-year average, excluding maximum and minimum years.

With the exception of White Bluff 1, EPA's approach of eliminating the maximum and minimum values results in higher baseline SO₂ emissions compared to averaging the entire 5-year period. In all cases, there is at least one other approach that would result in lower baseline SO₂ emissions compared to EPA's approach. By overestimating the baseline SO₂ emissions, EPA overstates the amount of SO₂ that would be removed and, thus, overstates the cost-effectiveness of the FGD retrofit projects.

2.2 SO₂ Emission Reduction

SO₂ emission reductions were estimated incorrectly by EPA for White Bluff and Independence. For each unit, EPA identified the maximum monthly SO₂ emission rate in the baseline period of 2009 to 2013 and then calculated the percent reduction that would be required to achieve a controlled emission rate of 0.06 lb/MMBtu. The percent reduction calculated was then multiplied by the baseline emission tons to determine the tons of SO₂ reduced. This methodology is incorrect because it assumes the baseline emissions calculated in the previous section are based on maximum monthly averages, which are significantly higher than the annual averages actually used to calculate baseline emissions.

The correct way to project the SO₂ emission reduction is to multiply the outlet emission rate of 0.06 lb/MMBtu by the average heat input to the boiler (MMBtu/year) from the baseline period. For example, the average heat input to White Bluff 1 over the baseline period of 2009 to 2013 was 55,829,551 MMBtu/year. Multiplying by 0.06 lb/MMBtu and then converting from pounds to tons results in estimated SO₂ emission reductions of 14,264 tons per year, as compared to EPA's 14,363. This method has been utilized by S&L on previous BART analyses, and has been accepted previously by EPA.

Table 2: SO₂ Emission Reductions for White Bluff and Independence

Unit	EPA Approach Using Maximum Monthly SO ₂ emission and 3-Year Baseline (tons)	Using 5-Year Average Heat Input and Baseline (tons)
White Bluff 1	14,363	14,264
White Bluff 2	15,221	14,353
Independence 1	12,912	12,607
Independence 2	13,990	13,655

Table 2 compares EPA’s incorrect methodology to estimate SO₂ emission reductions at the Entergy Units to the more accurate methodology described above of using the 5-year average heat input from the baseline period. EPA’s methodology overestimated the SO₂ emission reduction in all cases and therefore overstates the cost-effectiveness of the FGD retrofits at each unit.

2.3 SO₂ Emission Rate

EPA proposed SO₂ emission rates based on the assumption that a retrofit dry FGD will achieve a controlled SO₂ emission rate of 0.06 lb/MMBtu. In our experience, this assumption is unrealistic and cannot be sustained on a continuous, long-term basis. In several places, EPA cites the IPM dry FGD cost development document, which states: the “[r]ecommended SO₂ emission floor = 0.08 lb/MMBtu.”⁸

EPA’s proposal is too stringent to be achievable with the retrofit of an existing unit. A controlled SO₂ limit of 0.06 lb/MMBtu is not a realistic or sustainable value to maintain on a long-term basis when considering the normal variation in operation that occurs at all coal-fueled facilities. As noted in the IPM dry FGD document, the 0.06 lb/MMBtu emission rate corresponds to the lowest available SO₂ emission guarantees from dry FGD suppliers. Compliance with a vendor’s guarantee value is typically demonstrated during very short term testing conducted at ideal operating conditions. Vendor guarantees do not reflect controlled emission rates that may be achievable on a consistent long-term basis as the unit operation varies from design conditions.

Dry FGD control systems, like all large air pollution control systems, are not steady state control systems, and controlled SO₂ emissions will continually fluctuate in response to changing operating parameters. Operating parameters that may affect SO₂ emissions include the fuel sulfur content, boiler load, load changes, flue gas flow rate, and flue gas temperatures, all of which continually change during normal operation of the boiler.

⁸ Sargent & Lundy LLC, *IPM Model – Updates to Cost and Performance for APC Technologies, SDA FGD Cost Development Methodology*, March 2013.

Furthermore, as shown in Table 3, S&L investigated permit limits for dry FGD projects for Spray Dryer Absorber (SDA) projects similar to the dry FGD technology proposed for the White Bluff units, and Circulating Dry Scrubber (CDS) technology, which are more efficient dry scrubber systems because of increased flue gas and reagent contact through the use of a fluidized bed. As indicated, the lowest permit value for all units retrofitting dry FGD systems with averaging periods of 30 days was 0.09 lb/MMBtu, and that includes the more efficient CDS dry FGD systems. The last unit shown in the table includes the lowest permit limit of any of the dry FGD systems listed, but this value still contains the necessary margin because the averaging period is much longer (i.e. 12 months), and because the dry FGD system was installed as part of a new boiler project, so it was incorporated into the new unit design which inherently minimizes some of the design challenges associated with retrofitting, where non-ideal layouts can lead to non-ideal flow distribution inside the absorbers.

Projecting future emissions using the anticipated control system vendor guarantee (i.e., 0.06 lb/MMBtu) as EPA did is overly aggressive and provides no margin for normal operating conditions or long-term operation. A reasonable margin between the vendor guarantee value or design target, and the projected actual long-term achievable emission rate is needed to allow for normal fluctuations in the controlled emissions. In S&L’s opinion, an operating margin of at least 0.02 lb/MMBtu between the vendor guarantee and projected long-term emission rate is reasonable. As indicated in Table, using a limit of 0.08 lb/MMBtu to provide the recommended margin would still be an aggressive permit limit compared to other dry FGD projects.

Table 3: SO₂ Permit Limits for Dry FGD Projects

Reference Plant	Permit SO ₂ Limit	Permit Averaging Period
Plant 1 (SDA)	0.09 lb/MMBtu	30 day rolling
Plant 2 (SDA)	0.10 lb/MMBtu	30 day rolling
Plant 3 (SDA)	0.10 lb/MMBtu	30 day rolling
Plant 4 (SDA)	0.10 lb/MMBtu	30 day rolling
Plant 5 (SDA)	0.10 lb/MMBtu	30 day rolling
Plant 6 (SDA)	0.10 lb/MMBtu	30 day rolling
Plant 7 (CDS)	0.09 lb/MMBtu	30 day rolling
Plant 8 (CDS)	0.10 lb/MMBtu	30 day rolling
Plant 9 (CDS)*	0.07 lb/MMBtu	12-month rolling average

*This unit was a new unit, not a retrofit

EPA’s approach to estimating controlled SO₂ emission rates is incorrect and based on a misunderstanding of the actual performance and operation of dry FGD technology. By using this approach, EPA is overestimating the tons of SO₂ removed and thus overstating the cost-effectiveness of the retrofit FGD control systems.

3. Comments to the Cost TSD – Annualized Cost Errors

S&L's remaining comments are focused on EPA's Cost TSD. Our comments follow the same organization of EPA's Cost TSD document and are contained in the following sections.

3.1 Cost TSD, Section 2 – SDA Cost Analysis Methodology

EPA states that the “Control Cost Manual uses the overnight method of cost estimating, widely used in the utility industry.”⁹ To support this conclusion, EPA references its own characterization of the CCM methodology published in the preamble to the Oklahoma Regional Haze FIP.¹⁰ Using the overnight methodology, EPA removed certain costs from the SDA cost estimate, including Owner's costs and interest incurred during the construction period. We disagree that the CCM describes an overnight approach to calculating capital costs. The CCM does not once define or even mention the overnight methodology as being the basis for estimating costs. Rather, the CCM describes a constant dollar approach that annualizes all capital costs and O&M costs (on a constant-dollar basis) over the useful life of the project.

In the Oklahoma rule EPA cited to an Energy Information Administration (EIA) document as support for using the overnight cost estimating concept. In fact, EPA stated that “EIA presents all of its projected plant costs in terms of overnight costs.”¹¹ However, this is a mischaracterization of the methodology the EIA uses to develop capital costs for new power generation. The EIA document upon which EPA relied includes a clarifying footnote that states: “Starting from overnight cost estimates, EIA's electricity modeling explicitly takes account of the time required to bring each generating technology online and the costs of financing construction in the period before a plant becomes operational.”¹² Therefore, EIA cost evaluations take into account financing costs, including AFUDC, one of the line items EPA insisted that Entergy remove¹³ from the SDA capital cost estimate

Finally, EPA states that the overnight method is appropriate for BART determinations “because it allows different pollution controls equipment to be compared in a meaningful manner.”¹⁴ However, excluding financing costs will bias the cost-effectiveness comparison toward the high-capital options with extended construction periods. Project financing costs such as AFUDC may be minimal on projects that do not require significant capital and with short construction periods, but can be very significant on projects with large capital costs and extended construction periods. Excluding financing costs from the capital cost estimate results in the high-capital cost option appearing more cost-effective. Including financing costs allows the analyst to compare projects with varying capital requirements and varying construction periods.

3.2 Cost TSD Section 2.3 – Use of the 2009 Alstom Cost Analysis

EPA invited Entergy to clarify certain issues associated with Alstom's 2010 quotation, including a misunderstanding regarding the scope of the dry FGD vendor's contract. In S&L Report #012831 of our comments, we have included a report that explicitly describes the scope of supply for the dry FGD vendor as compared to the balance of plant (BOP) scope of work. EPA made several incorrect assumptions regarding Alstom's scope that led to incorrect adjustments to the BOP cost estimate, as described in Section 3.3 of our comments. Furthermore, EPA's approach to escalating the Alstom quotation was incorrect as described in Section 3.5 of our comments.

3.3 Cost TSD Section 2.4 – Use of the S&L Balance of Plant Costs

EPA mistakenly subtracted BOP costs because they mistakenly believed the equipment to be included in Alstom's scope. As described in S&L Report #012831, the reagent handling system, which feeds the dry FGD supplier's reagent preparation system were not included in Alstom's scope. The "Dry FGD Island" supplied by the dry FGD vendor includes lime day bins, slakers, slurry transfer tanks, slurry transfer pumps, slurry storage tanks, and slurry feed pumps. The BOP system includes the cost associated with the "Reagent Handling System," which includes a rail delivery and unloading system for the lime, new rail spur, renovation of existing rail spur, delivery shed building, long-term storage silos, and a pneumatic conveying system to transfer the lime reagent from the long-term storage silos to the day bins, which are within the dry FGD vendor's scope.

We agree with EPA's comment that including the NO_x control equipment for Units 1 and 2 was an oversight and should not be incorporated into the Dry FGD estimates.

EPA mistakenly subtracted a total of \$1,754,000 from the BOP quote because they mistakenly believed that all of the ductwork to be in Alstom's scope. The Dry FGD supplier's scope only includes ductwork between the dry FGD, the baghouse, and the booster fans. The ductwork to supply the flue gas to the SDA and the ductwork from booster fans to the existing chimney are within the BOP scope.

EPA mistakenly deleted a total of \$255,000 to paint the Chimney because it did not understand this line item. Due to lower temperatures and higher moisture of the flue gas, downwash from the gas is more likely to occur and can lead to acid attack of concrete on the chimney shell; therefore, the costs to apply an acid resistant coating to the top 50 feet of the existing chimney shell was included in the estimate.

EPA mistakenly removed a total of \$390,000 for costs associating with replacing and recalibrating the Continuous Emission Monitoring Systems (CEMS). The CEMS equipment reflected in Entergy's BART analysis was required because the existing CEMS was not capable of measuring SO₂ concentrations in the controlled range with Dry FGD technology. The costs included in the original estimate to cover replacement of the existing equipment with new equipment rated for the lower SO₂ concentrations as well as the cost to calibrate and certify these

monitors including conducting a Relative Accuracy Test Audit (RATA) test.

Based on these comments, we have corrected EPA's cost subtractions in Table 4.

Table 4: Excluded BOP Costs (Corrected, Total for Both Units)

	Equipment	Material	Labor	Total
Total BOP Cost	\$45,561,000	\$35,120,000	\$80,863,000	\$161,544,000
Eliminate U1 NO_x Equipment	\$3,622,000	\$1,600,000	\$3,073,000	\$8,295,000
Eliminate U2 NO_x Equipment	\$3,622,000	\$1,600,000	\$3,073,000	\$8,295,000
Total Eliminated Cost	\$7,244,000	\$3,200,000	\$6,146,000	\$16,590,000
% BOP Items Reduced	15.90	9.11	7.60	N/A

EPA then adjusted additional cost items in the BOP estimate that were either percentages of the equipment, material, and labor costs or were related to equipment, material, and labor costs. EPA adjusted these items by applying the % reduction in cost of equipment, material and labor. Since EPA mistakenly removed cost items that should be included in the estimate, they over-estimated and misapplied percent reduction to the other items. In Table 4, we correct EPA's adjustments to remaining Entergy BOP costs by employing EPA's methodology but reducing the percentage factors to the values indicated in Table 5.

EPA excluded a total of \$51,733,667 from the estimate, but Tables 4 and 5 show that only \$20,724,543 was justified because NO_x control equipment had been included. Because of EPA's misconception as to the scope of work included in the BOP and Alstom estimates, they mistakenly concluded that costs were double-counted and removed \$31,009,123 (total for both units) in costs that should be included. This resulted in EPA overstating the cost-effectiveness to retrofit dry FGD systems at White Bluff.

Table 5: Adjustment to Remaining Entergy BOP Costs (Total for Both Units)

DESCRIPTION	EPA Cost TSD Reductions				Corrected Reductions*

3.4 Cost TSD Section 2.5 – Undocumented or Disallowed Cost Items

Owner's Costs include a variety of costs incurred by the owner to support the air pollution control project. Owner's Costs are project-specific, but generally include costs incurred by the Owner to manage the project, hire and retain staff to support the project, and costs associated with third party assistance associated with project development and financing. Owner's Costs typically include, but may not necessarily be limited to:

- Site investigations (geotechnical, hydrology, etc.) for project design
- Environmental permitting/approvals
- Insurance during construction
- Site security during construction
- Transmission interconnection (if applicable)
- Fuel interconnection (if applicable)
- Owner's mobilization costs
- Owner's project management and support staff
- Insurance advisor
- Labor relations consultant
- Tax consultant
- Financial advisor
- Legal advisor
- Market consultant
- Community relations/community outreach program.

Owner's Costs are real costs that the owner will incur during the project and are typically included in cost estimates prepared for large air pollution control retrofit projects. In fact, U.S. EPA's Coal Quality Environmental Cost (CUECost) model includes Owner's Costs (or "Home Office" costs) in its air pollution control system cost estimating workbook and interrelated set of spreadsheets.¹⁵ CUECost uses a factor of 10% of the total installed cost to estimate Owner's Costs and Engineering Costs for limestone forced oxidation and lime spray dryer control systems.

To address the items in this section, we included a section in S&L Report #012831 that describes Entergy's Owner's costs and how they were developed. We believe EPA deleted these Owner's costs because EPA did not understand how they were defined and therefore, incorrectly assumed that they did not reflect real costs to Entergy. In total, EPA removed \$41,741,743 per unit from the original estimate which should be included. Removing these costs resulted in EPA overstating the cost-effectiveness to retrofit dry FGD systems at White Bluff and Independence. Detailed explanations of these costs are included in S&L Report #012831 to help EPA understand

¹⁵ See, Coal Utility Environmental Cost (CUECost) Workbook Development Documentation Version 5.0, prepared by U.S. EPA, September 2009, pages 17 and 34. Appendix B, pages B-3 and B-6.

these costs.

3.5 Cost TSD Section 2.6 – Escalation

We agree with EPA’s assertion that the application of escalation is allowed by the CCM.¹⁶ However, EPA’s method of using Chemical Engineering Plant Cost Indices (CEPCI) to escalate costs to the year 2013 resulted in severely underestimating the costs associated with escalation. CEPCI are sometimes used to estimate escalation by multiplying base costs by the ratio of the index for the year costs are to be escalated to the index for the year in which the costs were originally generated. For example, EPA used CEPCI from 2009 (521.9) and 2013 (550.8) to escalate the FGD costs from a 2009 basis to a 2013 basis. Thus, EPA applied the following formula, $550.8/521.9 * \$247,856,184$ to obtain an estimated 2013 FGD cost of \$261,581,119 for both units.

Rather than estimating escalation of Alstom’s pricing from 2010, S&L (on behalf of Entergy) requested updated FGD pricing from Alstom in 2013¹⁷. We agree with a reference cited in the CCM and authored by EPA which states, “At best [cost indices] provide a cloudy mirror...there is no substitute for current price information obtained from suppliers of those goods and services.”¹⁸ Nothing illustrates EPA’s conclusion that cost indices are not to be substituted for supplier information better than comparing EPA’s escalation rate to the actual escalation rate indicated in Alstom’s budgetary quotations as shown in Table 6.

Table 6: Alstom Quotation Comparison (Total for Both Units)

Parameter	EPA	Vendor Quotation
FGD Cost 2009	\$247,856,184	\$247,856,184
FGD Cost 2013	\$261,581,119	\$297,904,000
Average Escalation	1.36%	4.7% per year

As shown in Table 6, EPA underestimated escalation significantly, resulting in underestimating the 2013 dry FGD costs by \$36,322,881 (total for both units). In fact, EPA applied CEPCI indices in several instances from 2008 that *de-escalated* costs, resulting in lower costs in 2013 as compared to 2008. We note specifically that EPA’s cost calculations ignored the updated 2012 direct annual costs provided by Entergy, and instead included the 2008 costs.¹⁹ Table 7 summarizes how EPA incorrectly estimated escalation in its analysis for White Bluff Unit 1 and corrects that by applying an average escalation rate of 4.7% to match the Alstom quotation. We note that information from Alstom showed their pricing escalated nearly equivalently for

¹⁶ See Cost TSD, Section 2.6, page 8

¹⁷ Updated FGD pricing from Alstom is used as the basis of the 2015 cost estimate documented in S&L Report #012831.

¹⁸ Escalation Indexes for Air Pollution Control Costs, United States Environmental Protection Agency, October 1995, pp. 3-4.

REVIEW OF EPA'S COST ANALYSIS FOR
ARKANSAS REGIONAL HAZE PROPOSED FIP

equipment/material (~4.8%) and for installation (~4.6%). Since the difference was negligible we applied the average 4.7% in the revised costs shown in Table 7. EPA's underestimation of cost escalation carried through their analysis and resulted in an incorrect reduction in the cost estimate of over \$42 million per unit.

Table 7: Summary of EPA's Escalation Errors (Per Unit)²⁰

Item	Entergy	EPA (2013)	Corrected Costs Including Escalation (2013)	Escalation Costs Omitted by EPA
Total Contractor Costs* (2010)	\$156,974,274	\$161,676,662	\$180,164,213	\$18,487,550
Contingency (2010)	\$20,875,711	\$21,501,073	\$23,959,697	\$2,458,624
Balance of Plant (2008)**	\$102,085,500	\$75,145,724	\$115,401,842	\$13,316,342
Balance of Plant Indirect Costs (2012) ***	\$9,768,175	\$0	\$10,227,279	\$1,494,175
Misc Contract Labor (2012)	\$4,583,719	\$0	\$4,799,154	\$215,435
Entergy Internal Costs (2012)	\$20,076,644	\$0	\$21,020,246	\$943,602
Capital suspense (2012)	\$8,348,276	\$0	\$8,740,645	\$392,369
Total Capital Investment (TCI)		\$258,323,459	\$319,525,752	
Direct Annual Costs (2008)	\$7,901,369	\$7,790,140	\$9,941,130	\$2,150,990
Indirect Annual Costs				
Overhead (2008)	\$2,572,707	\$2,536,491	\$3,236,859	\$700,368
Administrative Charges @ 2% of TCI		\$5,166,469	\$6,390,515	\$1,224,046
Property Tax @ 1% of TCI		\$2,583,235	\$3,195,258	\$612,023
Insurance @ 1% of TCI		\$2,583,235	\$3,195,258	\$612,023
Total Indirect Annual Costs		\$12,869,429	\$16,017,889	
Total Escalation Costs Underestimated by EPA				\$42,607,547

* This item reflects the updated dry FGD pricing received in 2013

** As EPA did, this item subtracts the excluded BOP costs discussed in Section 3.3 before applying the escalation

*** In the Cost TSD, EPA incorrectly used the 2008 BOP Indirect Costs from the Revised Bart Five Factor Analysis, SDA Cost analysis rather than the 2012 BOP Indirect Costs as identified. The differential between the 2008 and 2012 BOP Indirect Costs (\$1,035,071) was included in the column for Escalation Costs Omitted by EPA.

²⁰ See Cost TSD, Table 5 on page 10

3.6 Cost TSD Section 2.7 – Operating and Maintenance (O&M) Costs

Although EPA claims in its proposal that it relied on the methods and principals contained within the Control Cost Manual in developing its individual control technology cost estimates, in the supporting Cost TSD EPA stated that “we can compare Entergy’s O&M costs to those obtained through the use of our IPM SDA cost model.”²¹

The IPM model and the Control Cost Manual provide two entirely different approaches to calculating control system capital and O&M costs. IPM is described by EPA as a multi-regional, dynamic, deterministic linear programming model used by EPA to analyze system-wide impacts of air emissions policies on the U.S. electric power sector in the 48 contiguous states and the District of Columbia.²² The model has been used by EPA to analyze impacts associated with proposed regulatory programs such as the Clean Air Interstate Rule (CAIR) and Mercury and Air Toxics Standard (MATS). The primary purpose of the model is to provide forecasts of least-cost capacity expansion, electricity dispatch and emission control strategies for meeting energy demand and environmental, transmission, dispatch and reliability constraints. The model includes cost modules for various air quality control technologies, and S&L developed the cost algorithms used in the IPM model to estimate costs associated with DSI, SDA, and wet FGD control systems.²³ The IPM model is not referred to in either the Control Cost Manual or the BART Guidelines as an acceptable tool to develop site specific capital or O&M cost estimates.

Cost algorithms in the IPM model were developed based on a statistical evaluation of cost data available from various industry publications, and do not take into consideration site-specific cost issues.²⁴ The primary purpose of the IPM cost modules is to provide generic order-of-magnitude costs for various air quality control technologies that can be applied to the electric power generating industry on a system-wide basis, not on an individual unit basis. By necessity, the cost algorithms were designed to require minimal site-specific information available from publicly available sources. Because of the limited number of site-specific inputs, the IPM cost algorithms provide order-of-magnitude control system cost estimates, but they do not provide case-by-case project-specific cost estimates meeting the requirements of the BART Guidelines, nor do the IPM equations incorporate the cost estimating methodology described in the Control Cost Manual.

Regarding O&M costs for SDA FGD systems, the IPM model includes the following assumptions that are not consistent with a site-specific O&M cost estimates:

- A fixed quantity of additional personnel to operate the equipment is included, not accounting for site-specific project and staffing needs;

²¹ See Cost TSD, Section 2.7, page 9.

²² See, EPA website: www.epa.gov/airmarkt/progsregs/epa-ipm/.

²³ See, e.g., IPM Model- Updates to Cost and Performance for APC Technologies Wet FGD Cost Development Methodology, Sargent & Lundy LLC, March 2013.

²⁴ *Id.*, at page 1.

- While we agree with the general practice of estimating maintenance material and labor costs as percentage of capital costs, the IPM model does not estimate site-specific capital costs sufficiently upon which to apply this percentage, and the assumed percentage cannot be modified to accommodate project specific requirements;
- The assumptions incorporated in the maintenance material and labor costs are propagated into the administrative labor item, and is therefore limited by the same items as the previous item;
- Reagent consumption assumes a stoichiometry that cannot be modified to match vendor-supplied guarantees for a specific application;
- Reagent consumption also depends upon a flue gas temperature into the SDA of 300°F and cannot be modified to apply site-specific temperatures;
- Reagent consumption also depends upon lime purity, which the IPM model assumes to be 90% and cannot be modified to match actual reagent supply information;
- The IPM model estimates water consumption based on gas flow and fuel sulfur levels instead of performing site-specific calculations using actual fuel properties and operating conditions;
- Waste generation is a function of the assumed lime stoichiometry discussed above as well as an assumed moisture content of 10% that cannot be modified to match vendor-supplied mass balances for specific applications; and
- The SDA flue gas pressure drop estimate included in the IPM model is an average value based on flue gas flow rate and sulfur levels instead of performing site-specific calculations that consider the actual fuel properties, operating conditions, and actual equipment sizing and arrangement.

EPA's use of IPM to benchmark O&M costs is thus not an appropriate choice for a unit-specific analysis consistent with BART guidelines. By relying on the IPM cost modules to verify dry FGD O&M costs, EPA did not adequately evaluate and account for potential project-specific site constraints that Entergy would incur to operate the FGD control systems EPA is proposing. In addition, using the IPM cost algorithms to calculate FGD control system capital or O&M costs is inconsistent with the case-by-case BART cost analysis described in the BART Guidelines for at least two reasons. First, the IPM model does not account for unit-specific design and operating parameters that can affect control system design and costs, including operating costs. Second, the IPM cost equations do not take into consideration site-specific conditions that could affect the O&M costs to operate the control system.

Please see additional comments in the next section of our comments (3.7), addressing EPA's adjustment of the O&M cost estimates to account for lower coal sulfur.

3.7 Cost TSD Section 3.1 – Entergy's Coal Sulfur Assumption

EPA states that an uncontrolled SO₂ emission rate of 2.0 lb/MMBtu at White Bluff is “far in excess of sulfur level of the coals it has historically burned,” and concludes, “[t]hus Entergy has costed SO₂ scrubber systems for the White Bluff facility that are oversized compared to its historical needs.” Based on this conclusion, EPA adjusts the capital and O&M costs using a

design sulfur level selected by EPA. While we agree with EPA that direct O&M costs be revised to 0.68 lb/MMBtu, this sulfur level is completely inadequate for the Dry FGD equipment design basis.

EPA correctly assumes that the 2.0 lb/MMBtu design basis was to preserve fuel flexibility, but their conclusions that, "either (1) this higher cost be balanced against its greater SO₂ reduction potential, or (2) that the scrubber system's capability and cost be adjusted down to match the facility's historical emissions," are without basis and inconsistent with BART guidelines.

The SO₂ emission reduction calculation depends upon the baseline emissions, baseline heat input, and the required outlet emission rate (see Section 2.2 of our comments). SO₂ emission reduction does not depend on the fuel sulfur levels selected for FGD system design, neither the BART guidelines nor the CCM address evaluating potential future SO₂ reduction based on design fuels as part of the BART analysis or cost estimating methodology. Therefore, EPA's first conclusion that the higher costs be balanced against greater SO₂ reduction potential is inconsistent with BART requirements and has no basis.

Although the BART guidelines and the CCM both account for the development of a design basis, there are no specific requirements that air pollution control design be tied to historical operating trends. Therefore, EPA's second conclusion that capital costs must be adjusted to match historical emissions is arbitrary and without basis.

Based on its erroneous conclusions, EPA selected a maximum monthly fuel sulfur level of 0.68 lb/MMBtu as the design basis used to estimate the capital costs. Figure 1 illustrates why the use of White Bluff's maximum monthly fuel sulfur level is completely insufficient. The ability to reduce SO₂ emissions depends critically upon the amount of reagent, or lime that can be added to the FGD system. With a 0.68 lb/MMBtu design basis, the reagent preparation and delivery equipment would be inadequately sized to add lime when sulfur levels increase beyond that level. As shown in Figure 1, EPA's design basis would result in emissions above the proposed emission rate for almost half of the operating time. This design approach would require limiting fuel sulfur levels to below 0.68 lb/MMBtu to ensure continuous compliance. If this is the approach EPA is intending, then the cost analysis would need to be revised to incorporate significant additional costs associated with fuel purchasing limitations. We did not include any additional O&M costs associated with fuel limitations because we believe EPA selected the design basis due to a lack of experience rather than intending to place enforceable limits on fuel purchasing at White Bluff station.

Figure 1: 2014 SO₂ Emissions for White Bluff 1²⁵

While we believe that the 2008 design basis of 2.0 lb/MMBtu was appropriate at that time based on the potential to fire fuels with higher sulfur levels, based on more recent information, Entergy now believes that they will not purchase fuels with sulfur levels higher than 1.2 lb/MMBtu. The operating data shown in Figure 1 confirms that 1.2 lb/MMBtu would result in a design basis that would ensure continued compliance with EPA's proposed FIP emission rates. Therefore, we have provided a revised cost estimate based on 1.2 lb/MMBtu. To illustrate the small difference in capital costs associated with the revised design basis (1.2 lb/MMBtu versus 0.68 lb/MMBtu), S&L has included a sensitivity analysis in S&L Report #012831.

As discussed previously, we agree that it is appropriate to base direct O&M cost estimates on 0.68 lb/MMBtu fuel sulfur levels to represent average operational costs. However, EPA's adjustment factor of 0.5823 applied to direct O&M costs severely underestimated these costs. In agreement with EPA's sulfur basis, S&L developed O&M costs for the 0.68 lb/MMBtu operating case in S&L Report #012831 based on site specific consumption rate estimates and unit costs. Our report estimated O&M costs including direct variable and fixed O&M costs to be a total of \$10,166,000 per unit in the first year. By comparison, EPA's calculation scales direct O&M costs of \$7,790,140 by 0.5823, resulting in direct O&M costs of \$4,536,199 per unit being

²⁵ Downloaded from EPA's Clean Air Market Database.

included in its cost-effectiveness calculation.²⁶ This methodology underestimated direct O&M costs by \$5,629,801 per unit.

In addition, EPA applied the same O&M factor of 0.5823 to the indirect annual costs, including overhead, administrative charges, property tax and insurance, all of which depend on capital cost.²⁷ Therefore, assuming EPA's capital cost scaling methodology for capital cost is correct (which we do not believe is the case), then EPA should have applied the 0.9584 factor used to correct capital costs to the indirect annual costs. EPA's methodology underestimated indirect O&M costs by \$4,840,192 per unit.

3.8 Cost TSD Section 4.1 – EPA's Conservatism in Cost Estimating

EPA lists two assumptions it believes are conservative in its Cost TSD. In one assumption, EPA noted that amortization from the 2008 S&L cost analysis was 40 years, but they lowered the remaining useful life to 30 years, which increases the cost-effectiveness. EPA's estimate is not conservative with regard to equipment life because, as EPA states, they, "typically assume a 30 year equipment life for scrubbers,"²⁸ and the 2008 amortization value from S&L was not intended to be used to conduct the BART analysis. Furthermore, as discussed in Section 3.9, the actual remaining life of these units is far below what EPA assumed.

In the second assumption, EPA concludes that two absorber vessels are not required and, thus, a 7% cost savings that could have been realized was not applied. We do not believe EPA is qualified to design dry FGD systems, and therefore not qualified to evaluate the number of vessels that are suitable for White Bluff. Dry FGD systems of this type have not been applied to units of this size, and the dry FGD supplier quoted three absorber vessels for this application based on their expertise. EPA cites no reference where fewer absorber vessels have been installed for a unit with an identical design basis, and therefore its assertion that two absorber vessels is adequate is arbitrary and without basis.

3.9 Remaining Useful Life

EPA states, "With regard to consideration of the remaining useful life of the units, we are not aware of any enforceable shutdown date for the Entergy White Bluff Plant, nor did Entergy's evaluation indicate any future planned shutdown."²⁹ Therefore, EPA utilized 30-years as the remaining useful life in its cost-effectiveness calculations. As stated in Entergy's comments to the proposed rule, Entergy proposes to cease coal-firing at the White Bluff units between 2027 and 2028. The proposed rule requires that the FGD controls and White Bluff be operational 5 years after the effective date of the rule. Assuming the effective date of the final rule is one year after the comment period closes, then the White Bluff FGD's will need to be operating by July of

²⁶ See, EPA-R06-OAR-2015-0189-0093-White Bluff_R6 cost revisions2.xlsx, tab "Cost-Effectiveness" Cell D4.

Final

18.

2021. Based on the coal-cessation dates of White Bluff Units 1 and 2, the remaining useful life of these FGD systems is therefore between 6 and 7 years, instead of 30 years used in EPA's analysis.

4. Cost TSD Section 5 – Inclusion of Independence under Reasonable Progress Goals (RPGs)

EPA included Entergy's Independence Plant in its RPG analysis based on annual emissions from the facility.³⁰ It is beyond the scope of S&L's comments to address the basis upon which EPA decided to include Independence in its RPG analysis for Caney Creek and Upper Buffalo. Instead, our comments focus on the inconsistencies and errors included in EPA's RPG analysis for the Independence station.

In EPA's RPG analysis for SO₂ Controls, EPA concluded that the units at White Bluff and Independence Stations are similar enough to apply "the total annualized dry FGD and wet FGD costs [they] developed for the White Bluff units to the Independence units."³¹ EPA then calculates the cost-effectiveness to retrofit FGD systems at Independence by adjusting the White Bluff cost effectiveness calculations to account for the differences in SO₂ emissions at Independence. This approach is flawed for several reasons. First, this approach includes all of the errors in EPA's cost-effectiveness analysis for White Bluff as described in the preceding sections, including errors in calculating baseline emissions, errors in calculating emission reductions, and errors associated with estimating annualized costs. Second, applying the White Bluff annualized costs to Independence is inconsistent with EPA's RPG guidance which requires cost estimates based on design parameters be developed for air pollution control systems.

To determine whether air pollution controls would be required at Independence Units 1 & 2 to meet the Reasonable Progress Goals at Caney Creek and Upper Buffalo, EPA conducted an RPG four factor analysis. The four factor analysis is described in EPA's RPG Guidance Document, and includes an evaluation of: (a) costs of compliance; (b) time necessary for compliance; (c) energy and non-air impacts; and (d) the remaining useful life of the source.³² Regarding the first factor listed, costs of compliance, EPA suggests that, for stationary sources, the following steps be performed:

- a) Identify the emissions units to be controlled;
- b) Identify the design parameters for emission controls; and
- c) Develop cost estimates based upon those design parameters³³

EPA did not perform steps b and c of the RPG compliance cost evaluation. Rather, EPA relied upon an EIA database comparison as well as an aerial photo comparison of the two units to justify applying the White Bluff FGD costs to Independence. The EIA information does not contain any information that would be used to set the design basis for either FGD system;

³⁰ See 80 Fed. Reg. 18,991 (April 8, 2015).

³¹ *Id.*, at page 18,992.

³² See "Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program," U.S. EPA June 1, 2007, pg 1-3.

³³ *Id.*, at page 5-1.

therefore it cannot be used to conclude the FGD system design at Independence would be identical to White Bluff. Furthermore, EPA's use of aerial photos to indicate visual similarities between White Bluff and Independence ignores many site-specific factors that cannot be captured in a Google Earth image downloaded from the internet. Some of the site-specific factors that EPA did not account for by using this approach and which could result in different costs to retrofit FGD technology at Independence as compared to White Bluff include:

- EPA proposes the same timeline for compliance for White Bluff and Independence which will add significant labor costs due to the amount of skilled labor that would be required to construct four FGD systems in the same time period;
- EPA did not review plant operating data, such as flue gas temperatures, which affect flue gas volume, potentially requiring different equipment sizing for Independence;
- EPA did not review operating and maintenance practices at Independence, which could result in different O&M costs;
- EPA did not assess differences in underground utility interferences that could potentially change the equipment arrangement at Independence;
- EPA did not conduct subsurface geotechnical investigations to determine differences in soil conditions or distances to reach bedrock that would impact foundation design or seismic design requirements;
- EPA did not assess other seismic design requirements such as seismic risk or magnitude of potential earthquakes to determine steel design differences that may be required; and
- EPA did not assess differences in wind loads which could impact foundation and structural steel design.

In its guidance document, EPA states, “[f]or additional guidance on applying the cost of compliance factor to stationary sources, you may wish to consult the BART guidelines.”³⁴ We note that, for EPA's RPG analysis for Independence, EPA did not revisit any of the steps required as part of a BART analysis; therefore, EPA ignored other lower cost technologies or methodologies to reduce SO₂ emissions at Independence station. EPA's inherent assumption is that BART-level SO₂ reductions are required at Independence to meet the RPGs, but it does not adequately support that assumption. EPA modeled visibility impacts of SO₂ reductions assuming FGD systems would be retrofitted at Independence, but they failed to conduct modeling using any other technology or methodology that could provide more cost-effective SO₂ reductions.

Finally, EPA also states in its RPG guidance document that for, “individual, large scale sources, simple cost effectiveness estimates based on a dollar-per-ton calculation may not be as meaningful as a dollar-per-deciview calculation.”³⁵ EPA's CENRAP modeling showed that the cumulative benefit of installing all of the controls proposed in the FIP would result in visibility benefits at Caney Creek of only 0.21 dv and at Upper Buffalo of only 0.19 dv.³⁶ Considering that

³⁴ *Id.*, at page 5-1.

³⁵ *Id.*, at page 5-2.

³⁶ See 80 Fed. Reg. 18,998, Table 67.

Independence represents only approximately 36% of the SO₂ point source emissions and 29% of the point source NO_x emissions in Arkansas, Entergy estimated the visibility improvement due to retrofitting FGD systems at Independence would be approximately 0.08 dv at Caney Creek and 0.07 dv at Upper Buffalo. Although we do not support EPA’s use of the White Bluff cost estimates for Independence, we applied the White Bluff costs to retrofit dry FGD and the estimated visibility improvement due to retrofitting dry FGD systems at Independence to estimate dollar-per-deciview as suggested in EPA’s RPG guidance document. Table 8 shows that retrofitting dry FGD systems at Independence is clearly not cost effective when considering the insignificant visibility improvements.

Table 8: Dollar-Per-Deciview Reduction for Dry FGD at Independence

Class I Area	Caney Creek	Upper Buffalo
Estimated Visibility Improvement³⁷	0.08	0.07
Revised Annualized Costs³⁸	\$106,765,022	\$106,765,022
\$/Adv	\$1,334,562,775	\$1,525,214,600

³⁷ The CENRAP modeling includes SO₂ and NO_x impacts; therefore, the numbers shown likely overestimate the visibility improvement based solely on SO₂ reductions.

³⁸ Annualized costs for Retrofitting Dry FGD at White Bluff 1 and 2 from S&L Report #012831 were used assuming a 30-year remaining useful life.

5. CONCLUSION

S&L reviewed the approach EPA takes in its proposed FIP for Arkansas, including EPA’s determination of costs for retrofit dry FGD scrubbers, and EPA’s evaluation of annual SO₂ emission reductions. Our analysis identifies several areas where EPA overstates the cost-effectiveness (\$/ton of SO₂ removed) of the dry FGD retrofits that EPA would require in its FIP. As discussed in this analysis, cost-effectiveness is influenced by two variables: the total annualized cost to retrofit FGD controls (\$/yr) and the corresponding reduction in annual SO₂ emissions (tons per year “tpy”). EPA’s approach does not accurately calculate either variable. Table 9 shows how the approach EPA took understated the annualized cost of the control systems and the adjustments S&L made to correct EPA’s errors.

Table 9: Adjustments to EPA’s Annualized Cost for a Single Unit at White Bluff

Item	Total Capital Investment (\$)	Annualized Cost (\$/year)
EPA FIP	\$247,537,295	\$31,981,230
Corrected BOP Cost Exclusions	\$263,041,857	\$33,230,898
Corrected Owner’s Cost Exclusions	\$304,783,600	\$36,595,282
Corrected Escalation	\$347,391,147	\$40,029,450
Corrected Operating Costs	\$347,391,147	\$50,499,444
Remaining Useful Lifetime Adjustment*	\$347,391,147	\$86,975,068 to \$95,381,830
2015 Estimate (S&L Report #012831) *	\$536,185,000	\$109,681,936 to \$122,657,613
Differential from EPA FIP*	+ \$99,853,852	+ \$54,993,838 to \$63,400,600

* Entergy proposes to cease to use coal at White Bluff 1 and 2 between 2027 and 2028; therefore, the annualized costs are shown as a range based on a remaining useful life of 6 or 7 years.

In addition, Table 10 shows how EPA’s approach overstated the tons of SO₂ that would be removed by its FIP-imposed dry FGD and the adjustments S&L made to correct EPA’s mistakes.

Table 10: Adjustments to EPA’s SO₂ Emission Reductions

Item	White Bluff 1 (tons)	White Bluff 2 (tons)
EPA FIP	14,363	15,221
Corrected Baseline Emission Calculation	14,474	14,617
Corrected SO ₂ Emission Reduction Calculation	14,264	14,353
Differential from EPA FIP	-99	-868

EPA’s errors resulted in severely overstating the cost-effectiveness to retrofit dry FGD systems at White Bluff 1 and 2 (and then by extension in its reasonable progress analysis for Independence 1 and 2). Table 11 summarizes how EPA’s errors systematically underestimated cost and overstated the cost-effectiveness to install these dry FGD systems. As Table 11 indicates when the errors are corrected and updated costs incorporated, retrofitting dry FGD systems at these units is clearly not cost-effective.

Table 11: Summary Cost-Effectiveness Impacts

Item	White Bluff 1 (\$/ton)	White Bluff 2 (\$/ton)
EPA’s Cost Effectiveness	\$2,227	\$2,101
Corrected Baseline Emission Calculation	\$2,210	\$2,188
Corrected SO ₂ Emission Reduction Calculation	\$2,242	\$2,228
Corrected BOP Cost Exclusions	\$2,330	\$2,315
Corrected Owner’s Cost Exclusions	\$2,566	\$2,550
Corrected Escalation	\$2,806	\$2,789
Corrected Operating Cost	\$3,540	\$3,518
Corrected Remaining Useful Life *	\$6,097 to \$6,687	\$6,060 to \$6,646
2015 Estimate (S&L Report #012831) *	\$7,689 to \$8,599	\$7,642 to \$8,546
Differential from EPA FIP¹	+ \$5,462 to \$6,372	+ \$5,541 to \$6,445

* Entergy proposes to cease to use coal at White Bluff Units 1 and 2 between 2027 and 2028; therefore, the cost effectiveness values are shown as a range based on a remaining useful life of 6 or 7 years.

With respect to EPA’s RPG analysis for SO₂ controls, EPA did not follow its own guidance document when conducting its four factor analysis of Independence. EPA failed to consider lower cost options that could reduce SO₂ emissions at Independence and instead concluded that BART-level controls were required to meet RPG. EPA did not prepare cost estimates based on design parameters for FGD systems retrofit at Independence, as required by their RPG guidance document. EPA did not conduct a dollar-per-deciview analysis, as recommended in its RPG document for these analyses, to demonstrate the benefit of retrofitting dry FGD at Independence accounting for visibility benefits. When applying annualized costs to projected visibility improvements the result is **over \$1.3 billion/Adv** for Caney Creek and **over \$1.5 billion/Adv** for Upper Buffalo, which is clearly not cost effective.

1 - EPA did not list the heat input. EPA's analysis incorrectly assumes the annual average heat input as being the baseline SO2 emissions (tpy) divided by the monthly maximum emission rate (lb/MMBtu)

2 - EPA incorrectly applied the maximum monthly SO2 emission rate to determine the % reduction in SO2 to achieve 0.06

3 - EPA did not include this item. SO2 emission reduction is corrected to calculate it as [baseline annual average heat input (MMBtu/Yr)] * [the controlled SO2 emission rate (lb/MMBtu)] * [2000 lb/ton]

This report provides an update to the Best Available Retrofit Technology (BART) Five Factor Analysis for sulfur dioxide (SO₂) for Unit 1 (SN-01) and Unit 2 (SN-02) at Entergy Arkansas, Inc.'s (EAI's) White Bluff Steam Electric Station (White Bluff) as well as revising the SO₂ BART conclusion. EAI submitted the original BART Five Factor Analysis to the Arkansas Department of Environmental Quality (ADEQ) on February 21, 2013, with revisions on June 10, 2013 and October 15, 2013.

- Unit 1 (SN-01) is a primary boiler with a maximum net power rating of 850 megawatts (MW) and a nominal heat input capacity of 8,950 million British thermal units per hour (MMBtu/hr). The boiler burns sub-bituminous or bituminous coal¹ as the primary fuel and No. 2 fuel oil or biofuel as a start-up fuel, and it is currently equipped with an electrostatic precipitator (ESP) for particulate matter (PM) control.
- Unit 2 (SN-02) is identical in design to Unit 1. It is a primary boiler with a maximum net power rating of 850 MW and a nominal heat input capacity of 8,950 MMBtu/hr. The boiler burns sub-bituminous or bituminous coal² as the primary fuel and No. 2 fuel oil or biofuel as a start-up fuel, and it is currently equipped with an ESP for PM control.

Specific updates incorporated in this version of the report are outlined below.

1.1 REPORT UPDATES

This report includes the following updates to the previous SO₂ Five Factor Analysis for White Bluff Units 1 and 2:

1. Updating the baseline period to 2009-2013.
2. Incorporating new information regarding the remaining useful life (RUL) of the units.
3. Incorporating a new control scenario representing combustion of only low-sulfur coal (LSC).
4. Incorporating additional information (i.e., cost information and modeling results) related to control options involving Dry Sorbent Injection (DSI).
5. Updating all modeling to reflect the newest methodologies for dividing (“speciating”) particulate matter (PM or PM₁₀)³ emissions into its constituents.
6. Updating the SO₂ BART conclusion in consideration of the new information and updates listed above.

¹ The coal-fired units at White Bluff primarily burn sub-bituminous coal, but are permitted to burn bituminous or sub-bituminous coal. Only sub-bituminous coals were burned during the baseline periods evaluated in this analysis.

² Ibid.

³ All PM represented in this report is assumed to have a mass mean diameter smaller than ten microns.

1.2 SUMMARY OF UPDATED BART FIVE FACTOR ANALYSIS

Trinity conducted the below five-step analysis based on EPA's BART Guidelines⁴ in 40 CFR Part 51 and other EPA guidance⁵ to evaluate SO₂ BART for Units 1 and 2:

1. Identifying all available retrofit control technologies;
2. Eliminating technically infeasible control technologies;
3. Evaluating the control effectiveness of remaining control technologies;
4. Evaluating impacts and documenting the results; and
5. Evaluating visibility impacts.

The updated BART Five Factor Analysis concludes that combustion of LSC constitutes BART for Unit 1 and Unit 2 in light of the updated RUL. The proposed BART emission rate for SO₂ is 0.6 pounds per MMBtu (lb/MMBtu) on a rolling 30-day average.

⁴ The BART guidelines were published as amendments to EPA's Regional Haze Rule (RHR) at 40 CFR 51.308 on July 6, 2005.

⁵ April 26, 2012, letter from Mr. Guy Donaldson, EPA Region VI, to Mr. Anthony Davis, ADEQ.

2 INTRODUCTION AND BACKGROUND

In the 1977 amendments to the Clean Air Act (CAA), Congress set a national goal to restore national parks and wilderness areas to pristine conditions by preventing any future, and remedying any existing, man-made visibility impairment. On July 1, 1999, the U.S. EPA published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to pristine conditions in 156 specific areas across the United States known as Class I areas. The CAA defines Class I areas as certain national parks (larger than 6,000 acres), wilderness areas (larger than 5,000 acres), national memorial parks (larger than 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires States to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their state. On July 6, 2005, the EPA published amendments to its 1999 RHR, often called the Best Available Retrofit Technology (BART) rule, which included guidance for making source-specific BART determinations. The BART rule defines BART-eligible sources as sources that meet the following criteria:

- (1) Have potential emissions of at least 250 tons per year of a visibility-impairing pollutant,
- (2) Began operation between August 7, 1962, and August 7, 1977, and
- (3) Are included as one of the 26 listed source categories in the guidance.

A BART-eligible source is subject to BART if the source is “reasonably anticipated to cause or contribute to visibility impairment in any federal mandatory Class I area.” For the purpose of determining which sources are subject to BART, a 1.0 Δ dv change or more from an individual source is considered to “cause” visibility impairment, and a change of 0.5 Δ dv is considered to “contribute” to impairment, which therefore establishes 0.5 Δ dv as a numerical screening threshold for subject-to-BART determinations.⁶ According to the BART guidelines, the CALPUFF modeling system (CALPUFF) or any other appropriate dispersion model can be used to predict the visibility impacts.⁷ The model-predicted visibility impact, specifically when using CALPUFF the 98th percentile impact measured against natural background (and not the maximum impact), is compared to the 0.5 Δ dv threshold to determine if the source is anticipated to cause or contribute to the visibility impairment.⁸

Once it is determined that a source is subject to BART, a BART determination must address air pollution control measures for the source. The visibility regulations define BART as follows:

...an emission limitation based on the degree of reduction achievable through the application of the best system of continuous emission reduction for each pollutant which is emitted by...[a BART-eligible source]. The emission limitation must be established on a case-by-case basis, taking into consideration the technology available, the cost of compliance, the energy and non-air quality

⁶ “Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations; Final Rule,” 70 Fed. Reg. 39,116-18 (July 6, 2005).

⁷ Trinity and EAI assert that CALPUFF is not the most appropriate model for estimating visibility impacts. Due to its numerous inherent limitations (e.g., limited chemistry mechanism, distance limitations, blanket background ammonia values, etc.), CALPUFF does not yield reliable results. Furthermore, CALPUFF is no longer an EPA-preferred model, which further indicates CALPUFF’s unreliability. More advanced models like the Comprehensive Air Quality Model with Extensions (CAMx)—if processed appropriately—can yield more reliable characterizations of visibility impairment. Nevertheless (without waiver), CALPUFF modeling will continue to be presented in this report for consistency with past submittals.

⁸ Id. at 39,163.

environmental impacts of compliance, any pollution control equipment in use or in existence at the source, the remaining useful life of the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.

The BART Guidelines state that a BART determination should address the following five statutory factors:

1. Existing controls;
2. Cost of controls;
3. Energy and non-air quality environmental impacts;
4. Remaining useful life of the source; and
5. Degree of visibility improvement as a result of controls.

Further, the BART Guidelines indicate that the five basic steps in a BART analysis can be summarized as follows:

1. Identify all available retrofit control technologies;
2. Eliminate technically infeasible control technologies;
3. Evaluate the control effectiveness of remaining control technologies;
4. Evaluate impacts and document the results; and
5. Evaluate visibility impacts.

As described in the above-referenced, previous submittals, the boilers at White Bluff meet the three BART-eligibility criteria, and the existing visibility impairment is modeled at greater than 0.5 Δ dv in at least one Class I area. Thus, the White Bluff units are subject to BART.

3 EXISTING EMISSIONS AND BASELINE VISIBILITY IMPAIRMENT

Five Factor Analyses require the determination of unit-specific baseline visibility impairment values to which any post-control scenarios can be compared. The unit-specific baseline modeling analyses are built upon, but are distinguished from, the baseline (a.k.a., “screening”) modeling for the collection of BART eligible units at each source that is completed to determine if a BART eligible source is subject to BART. EAI is not updating the subject-to-BART determination at this time.

This section summarizes the baseline visibility impairment attributable to each of White Bluff’s units based on CALPUFF air quality modeling conducted by Trinity.⁹ Trinity conducted the modeling using the same protocol, methodologies, and inputs (except where specifically updated as described in this report) as presented in the October 15, 2013 submittal. The protocol and details method descriptions are not included with this report because nothing has changed and the CALMET dataset developed per the protocol has been used – and approved by EPA – numerous times since its development.

While this report updates the BART Five Factor Analysis for SO₂ emissions specifically, BART modeling must consider emissions of all visibility-affecting pollutants (VAP), including SO₂, oxides of nitrogen (NO_x), and speciated particulate matter, including filterable coarse particulate matter (PM_c), filterable fine particulate matter (PM_f), elemental carbon (EC), inorganic condensable particulate matter (IOR CPM) as sulfates (SO₄), and organic condensable particulate matter (OR CPM), also referred to as secondary organic aerosols (SOA).

3.1 BASELINE EMISSION RATES

The updated modeled NO_x and SO₂ emission rates for Unit 1 and Unit 2 are the highest actual 24-hour emission rates based on Clean Air Markets Database (CAMD) data from 2009-2013.¹⁰ The updated modeled PM₁₀ emission rates for Unit 1 and Unit 2 are based on emission factors from AP-42 for filterable PM₁₀ and condensable PM (with a 99.5 percent control efficiency for ESP applied to the PM₁₀ filterable fraction) used in conjunction with the average 2009-2013 coal heating value and ash content (as a percentage of mass).¹¹ Emission rates for specific PM₁₀ species were calculated using the monitored filterable PM rate and the National Park Service (NPS) “speciation spreadsheet” for *Dry Bottom Boiler Burning Pulverized Coal using only ESP*¹² except for SO₄, which was calculated using an Electric Power Research Institute (EPRI) methodology that considers the SO₂ to SO₄ conversion rate and SO₄ reduction factors for various downstream equipment.¹³ Table 3-1 summarizes the emission rates that were modeled for SO₂, NO_x, and PM₁₀, including the speciated PM₁₀ emissions.

⁹ See footnote 7, above.

¹⁰ The use of this baseline is a conservative approach. EAI would be justified in using a more recent baseline with lower emissions that would result in higher cost effectiveness values.

¹¹ AP-42, Chapter 1 External Combustion Sources, Section 1.1 Bituminous and Subbituminous Coal Combustion, Table 1.1-5, page 1.1-24 (September 1998).

¹² The baseline speciation is based on the NPS Workbook for a Dry Bottom Boiler burning Pulverized Coal using an ESP. Based on average 2009-2013 values, the following input values were used: heating value of 8,587 Btu/lb, 0.27% sulfur, 4.96% ash, 8,950 MMBtu/hr heat input, and a baseline total PM₁₀ emission rate of 119.2 lb/hr at both White Bluff Unit 1 and Unit 2. NPS: <http://www.nature.nps.gov/air/Permits/ect/index.cfm>.

3.2 BASELINE VISIBILITY IMPAIRMENT

Trinity conducted modeling to estimate the current visibility impairment attributable to Unit 1 and Unit 2 in four Class I Areas: Caney Creek Wilderness (CACR), Upper Buffalo Wilderness (UPBU), Hercules Glades Wilderness (HERC), and Mingo Wilderness (MING) using the CALPUFF dispersion model.¹⁴ Table 3-2 provides a summary of the modeled visibility impairment attributable to Unit 1 and Unit 2 based on the emission rates shown in Table 3-1. This table shows the 98th percentile impacts in Δdv and the number of days with impacts greater than 0.5 Δdv .

^A Meteorological data year modeled.

¹⁴ Due to an EPA-requested change in meteorological data (to a refined, or "NO OBS = 0", dataset), which excluded the Sipsey Class 1 Area from the modeling domain, Sipsey was not included in this analysis. See also footnote 7 above.

4.1 IDENTIFICATION OF AVAILABLE RETROFIT SO₂ CONTROL TECHNOLOGIES FOR UNIT 1 AND UNIT 2

The boilers burn primarily coal. Sulfur oxides, SO_x, are generated during coal combustion from the oxidation of sulfur contained in the fuel. SO_x emissions are almost entirely dependent on the sulfur content of the fuel and are generally not affected by boiler size or burner design. SO_x emissions from conventional combustion systems are predominantly in the form of SO₂. Since SO₂ is the predominant sulfur compound emitted from Unit 1 and Unit 2, the BART analysis is specific to emissions of SO₂. Reductions in emissions of SO₂ are expected to reduce visibility impairment by reducing sulfate (SO₄) formation.

Step 1 of the top-down control review is to identify available retrofit control options for SO₂. The available SO₂ retrofit control technologies for Unit 1 and Unit 2 are summarized in Table 4-1.

Table 4-1. Available SO₂ Control Technologies for Unit 1 and Unit 2

SO₂ Control Technologies
Fuel Switching – Low-Sulfur Coal (LSC)
Dry Sorbent Injection (DSI)
Dry / Semi-Dry Flue Gas Desulfurization (DFGD), e.g., Spray Dryer Absorber (SDA)
Wet Scrubbing, i.e., Wet Flue Gas Desulfurization (WFGD)

4.2 ELIMINATE TECHNICALLY INFEASIBLE SO₂ CONTROL TECHNOLOGIES FOR UNIT 1 AND UNIT 2

Step 2 of the BART determination is to eliminate technically infeasible SO₂ control technologies that were identified in Step 1.

4.2.1 Fuel Switching - Low-Sulfur Coal

With an achievable emission level of 0.6 lb/MMBtu, switching to LSC can reduce SO₂ emissions by approximately 8.75 percent compared to baseline levels.¹⁵

4.2.2 Dry Sorbent Injection

DSI involves the injection of a sorbent (e.g., Trona) into the exhaust gas stream where acid gases such as hydrogen chloride (HCl) and SO₂ react with and become entrained in the sorbent. The stream then passes through a particulate control device to remove the sorbent along with the entrained SO₂. The process was developed as a lower cost FGD option because the mixing of the SO₂ and sorbent occurs directly in the exhaust gas stream rather than in a separate vessel. Sorbent injection control efficiency depends on residence time, gas stream temperature, and limitations of the particulate control device.

¹⁵ Calculated based on a comparison of the maximum 30 boiler operating day SO₂ emission rate during the baseline period to the proposed limit for low-sulfur coal of 0.6 lb/MMBtu.

DSI is a technically feasible yet seldom used technology for moderate to high removal of SO₂ from coal-fired power plants, with limited full-scale installations for SO₂ control. A significant amount of testing of DSI for SO₂ control has been performed in recent years. This testing has shown that a wide range of performance is achievable (up to 80 or 90 percent SO₂ reduction in some cases). However, this testing has also shown that there are many factors that can impact the performance of these reagents, including particle size (milling), residence time, temperature, and the particulate collection equipment. The primary lesson learned through this testing is that each unit is unique, with various factors that can impact the achievable performance or required reagent feed rate. Different performance has even been seen on sister units. Therefore, it is critical to perform a demonstration or Proof of Concept test at each facility.

A demonstration has not to-date been performed on the White Bluff units to show the achievable SO₂ control and associated reagent feed rates. The cost reports developed by S&L, included in Appendix A, show predicted performance and required reagent rates based on Sargent & Lundy's (S&L's) extensive experience with DSI testing and previous work with the White Bluff units. Two DSI technologies are considered for White Bluff: "DSI", which would utilize the existing ESP, and "enhanced DSI", which would include installation of a fabric filter or baghouse. Enhanced DSI should achieve greater SO₂ reductions because the installation of a fabric filter increases residence time and improves collection efficiency to allow more sorbent to be injected. The S&L reports present predicted performance levels (SO₂ emission rates) for DSI and enhanced DSI of 0.35 lb/MMBtu and 0.15 lb/MMBtu, respectively. Because the actual performance and required reagent rates may vary from the predicted values due to unforeseen site-specific conditions, it is possible that the capital and annual costs represented in the S&L reports, and in Section 4.4.2 of this report, could also vary. If a significantly higher injection rate were actually required to achieve the same performance level (SO₂ emission rate) then the capital and annual costs, and corresponding cost-effectiveness of the DSI technologies, could dramatically increase.

Furthermore, DSI has yet to be demonstrated on similarly sized units to those at White Bluff. An important consideration for DSI technology is the design throughput of the system, beyond just the size and achievable performance (SO₂ emission rate). The largest DSI system installed and operating has a design feed rate of 12 tons/hour, while most of the installed systems inject approximately five to six tons/hour. The predicted injection rate for the White Bluff enhanced DSI case is approximately 15 tons/hour. The greater the injection rates, the more issues associated with supply and delivery logistics that arise. At 15 tons/hour (per unit) White Bluff would consume one railcar (100-ton capacity) of Trona every 3.3 hours if both units are operating at full load.

Prior to moving forward with DSI technology as a compliance strategy, a demonstration test would need to be performed to confirm the feasibility, achievable performance and balance of plant impacts (brown plume formation, ash handling modifications, landfill/leachate considerations and impact to mercury control). The balance of plant impacts have been addressed as part of the S&L cost reports based on typical assumptions, but would also be impacted should the design injection rate vary. Any compliance strategy which were to rely on DSI technology would need to be contingent on successful completion of a demonstration test.

4.2.3 Dry / Semi-Dry Flue Gas Desulfurization

Of the various designs for dry or semi-dry FGD systems, the most popular is the Spray Dryer Absorber (SDA) design. In the SDA design, a fine mist of lime slurry is sprayed into an absorption tower where the SO₂ is absorbed by the slurry droplets. The absorption of the SO₂ leads to the formation of calcium sulfite and calcium sulfate within the droplets. The heat from the exhaust gas causes the water to evaporate before the droplets reach the bottom of the tower, resulting in the formation of a dry powder that is carried out with the gas and collected with a fabric filter.

SDA systems can achieve control efficiencies ranging from 60 to 95 percent.¹⁶ SDA is a technically feasible option for control of SO₂ from Unit 1 and Unit 2. Based on a site-specific study completed by S&L, SDA could technically achieve an SO₂ emission rate of 0.06 lb/MMBtu at Unit 1 and Unit 2.

4.2.4 Wet Flue Gas Desulfurization

While WFGD is technically feasible, it is not expected to achieve significant reductions beyond DFGD/SDA and was eliminated in the previous analyses and in EPA’s final regulations (SIP approval and FIP). Accordingly, WFGD is not considered further in this analysis.

4.3 RANK OF TECHNICALLY FEASIBLE SO₂ CONTROL OPTIONS BY EFFECTIVENESS FOR UNIT 1 AND UNIT 2

The third step in the BART analysis is to rank the technically feasible options according to their effectiveness in reducing SO₂.

Table 4-2 provides a ranking of the control levels for the controls listed in the previous section.

Table 4-2. Control Effectiveness of Technically Feasible SO₂ Control Technologies

Control Technology	Achievable Emission Rate (lb/MMBtu) ^A
Semi-Dry Scrubber (SDA)	0.06
Enhanced DSI	0.15
DSI	0.35
Low Sulfur Coal	0.6

4.4 EVALUATION OF IMPACTS FOR FEASIBLE SO₂ CONTROLS FOR UNIT 1 AND UNIT 2

The fourth step in the BART analysis is the impact analysis, which evaluates the impacts for the control options deemed feasible in Step 2. This analysis typically is conducted to demonstrate that the most effective control technology does not necessarily constitute BART. The BART guidelines list the four factors to be considered in the impact analysis:

- Cost of compliance
- Energy impacts
- Non-air quality impacts; and
- The RUL of the source

Because the RUL of the source directly affects the cost of compliance, RUL is considered first.

¹⁶ EPA Basic Concepts in Environmental Sciences, Module 6: Air Pollutants and Control Techniques <http://www.epa.gov/eogapti1/module6/sulfur/control/control.htm>

4.4.1 Remaining Useful Life

EAI anticipates Unit 1 and Unit 2 will cease to use coal by end of year 2028, and, upon acceptance of the BART determinations contained herein in an approved SIP, is prepared to take an enforceable restriction to this effect.

4.4.2 Cost of Compliance

The capital costs and annual operating and maintenance costs for the considered control options, except for the LSC option, were developed by S&L and are included in Appendix A. The annual cost increase due to burning only LSC is based on a cost premium of \$0.50 per ton, which was the premium provided to EAI's fuel purchasing department by its coal suppliers. For the S&L-developed costs, two sets of values are presented. The first, in Table 4-3, is the actual cost estimated for each unit and control option. The second, in Table 4-4, is the estimated cost after excluding cost items that EPA has historically claimed should not be accounted for in BART cost effectiveness calculations. An example of an excluded cost is Allowance for Funds Used During Construction (AFUDC). AFUDC represents the interest expense incurred on the investment in a large capital project, such as a FGD installation, which can take several years to complete (≥ 5 years). Although interest expenses will certainly be incurred on such a project, and AFUDC is typically considered as part of the capital cost of such a project for standard accounting and rate-making purposes, EPA Region 6 has expressed concern with the inclusion of AFUDC and certain other costs. EAI disagrees and believes that determining the cost effectiveness of the control options must realistically reflect the actual cost of compliance. *See* EAI's comments on the proposed FIP.¹⁷ Nonetheless, for completeness, this analysis shows a range of cost effectiveness both including AFUDC and other costs and excluding those costs.

Trinity annualized the capital costs based on capital recovery periods reflecting the total amount of time that the control option could be employed until the unit ceases to use coal at the end of 2028. For the purpose of this report, the start of operation for the SDA option is assumed to be the end of 2021.¹⁸ Therefore, the capital recovery period for SDA is set at seven (7) years (2028 - 2021 = 7 years). The LSC and DSI options can be employed two (2) years earlier than SDA which, for purposes of this report, is assumed to be the end of 2019. Therefore, the capital recovery period for these control options is set at nine (9) years (2028 - 2019 = 9 years).

Trinity determined the values for annual tons of SO₂ reduced by subtracting the estimated controlled annual emission rate from the baseline annual emission rate. The baseline annual emission rate was based on the average rate for the 2009-2013 baseline period.¹⁹ The controlled annual emission rates were based on the lb/MMBtu levels listed in Table 4-2 multiplied by the future annual heat input, which was based on the average actual heat input from CAMD for the 2009-2013 baseline period. For the LSC scenario, "controlled" annual emission rates were based on an 8.75 percent decrease compared to baseline annual emission rates, which is estimated by comparing the maximum 30-boiler operating day rolling average to the controlled emission rate of 0.6 lb/MMBtu.

The cost effectiveness in dollars per ton of SO₂ reduced was determined by dividing the annualized cost of control by the annual tons reduced. Table 4-3 presents a summary of the cost effectiveness for each control

¹⁷ Entergy Arkansas Inc. "Comments On the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas" (EPA Docket ID No. EPA-R06-OAR-2015-0189), August 7, 2015, pp. 10-11.

¹⁸ October 27, 2021 per 81 Fed. Reg. Vol. 81, p. 66416. However, given that actual installation would take at least five years, SDA likely could not be installed until 2023 or later.

¹⁹ As noted above, this is a conservative baseline, and EAI would have been justified in using a more recent baseline with lower emissions that would have resulted in generally higher cost effectiveness values.

option. The cost of switching to low sulfur coal is less than \$1,200/ton of SO₂ reduced. The actual cost effectiveness of the add-on controls is economically infeasible at more than \$7,000/ton of SO₂ reduced. It's noted (without waiver) that the cost effectiveness of add-on controls even when excluding certain costs for which EPA has expressed concern (e.g., AFUDC), but that will be incurred as explained above, also results in economic infeasibility, at more than approximately \$5,400/ton.²⁰

Table 4-3. Summary of SO₂ Controls Cost Effectiveness for Unit 1 and Unit 2 Based on Actual Costs

Unit & Control Option	Baseline Emission Rate (tpy)	Controlled Emission Rate (tpy)	Capital Cost (\$MM)	Annualized Capital Cost (\$MM/yr)	Annual O&M Cost (\$MM/yr)	Average Cost Effectiveness (\$/ton)	Incremental Cost Effectiveness v. LSC (\$/ton)
SN-01 – LSC	15,939	14,544	0	0	1.60	1,150	
SN-02 – LSC	16,034	14,631	0	0	1.61	1,148

Table 4-4. Summary of SO₂ Controls Cost Effectiveness for Unit 1 and Unit 2 Based on Costs Adjusted for EPA-Exclusions for Illustration Purposes

Unit & Control Option	Baseline Emission Rate (tpy)	Controlled Emission Rate (tpy)	Capital Cost (\$MM)	Annualized Capital Cost (\$MM/yr)	Annual O&M Cost (\$MM/yr)	Average Cost Effectiveness (\$/ton)	Incremental Cost Effectiveness v. LSC (\$/ton)
SN-01 – LSC	15,939	14,544	0	0	1.60	1,150	
SN-02 – LSC	16,034	14,631	0	0	1.61	1,148	
SN-01 – DSI	15,939	9,770	154.79	23.76	14.91	6,269	7,764
SN-02 – DSI	16,034	9,807	154.79	23.76	14.91	6,211	7,683
SN-01 – Enhanced DSI	15,939	4,187	321.42	49.34	26.19	6,427	7,137
SN-02 – Enhanced DSI	16,034	4,203	321.42	49.34	26.19	6,384	7,088
SN-01 – SDA	15,939	1,675	364.83	67.71	9.60	5,420	5,883
SN-02 – SDA	16,034	1,681	364.83	67.71	9.60	5,387	5,846

²⁰ Issues raised on appeal of the federal plan include EPA's use of undervalued cost of controls. However, without waiver of any claims or arguments, EPA's estimates also support the conclusion that SDA is not cost effective. Using EPA's estimates of capital cost (\$247,709,875), total O&M cost (\$16,877,127), and emissions reductions (14,363 tpy for Unit 1 and 15,221 tpy for Unit 2), adjusted only to consider the shortened remaining useful life value discussed above, the average cost effectiveness values for SDA are \$4,376/ton for Unit 1 and \$4,129 for Unit 2.

4.4.3 Energy Impacts and Non-Air Quality Impacts

There are numerous energy impacts and adverse non-air quality environmental impacts associated with the add-on controls under consideration. Some examples related to the use of DSI include (a) the need for substantial storage and transportation – both delivery via rail and conveyance on site – of Trona, (b) the forced abandonment of the beneficial re-use of fly ash, and (c) potential negative impacts on the PM control device.²¹ These impacts are more fully addressed for all the considered control options in the S&L reports included in Appendix A.

4.5 EVALUATION OF VISIBILITY IMPACT OF FEASIBLE SO₂ CONTROLS FOR UNIT 1 AND UNIT 2

Trinity conducted an impact analysis to assess the visibility improvement achieved. The impact analysis compared the impacts associated with the baseline emission rates to the impacts associated with the maximum emission rates representative of each control option.

Table 4-5 summarizes the lb/hr emission rates that were modeled to reflect each control option. The NO_x and total PM₁₀ emission rates were modeled at the revised 2009-2013 baseline rates. The applicable NPS speciation spreadsheets were relied upon to determine emission rates for PM species.^{22,23,24} SO₄ emission rates were independently calculated using an EPRI methodology that considers the SO₂ to SO₄ conversion rate and SO₄ reduction factors for various downstream equipment.²⁵

4.6 BART FOR SO₂ FOR UNIT 1 AND UNIT 2

Based on the costs of the control options listed above, BART for Unit 1 and Unit 2, when considering the updated RUL, would be an emission level of 0.6 lb/MMBtu based on the use of low-sulfur coal.

**Petition for Reconsideration of the Revisions to the Regional Haze Rule by Southwestern
Public Service Company, Entergy Services, Inc., and Cleco Power LLC**

Southwestern Public Service Company (“SPS”); Entergy Services, Inc., on behalf of Entergy Corporation and its subsidiaries (collectively, “Entergy”); and Cleco Power LLC (“Cleco”) (collectively, “Petitioners”) respectfully petition the U.S. Environmental Protection Agency (“EPA” or “Agency”) for reconsideration of the final rule entitled “*Protection of Visibility: Amendments to Requirements for State Plans*,” Docket No. EPA-HQ-OAR-2015-0531.¹ Specifically, Petitioners request that EPA eliminate (1) provisions codifying an interpretation of the relationship between reasonable progress goals and long-term strategies; and (2) provisions pertaining to the reasonably attributable visibility impairment (“RAVI”) program. These provisions contradict the Clean Air Act (“CAA” or “Act”) and EPA’s previous regulations and impose unnecessary and potentially staggering costs without achieving any corresponding visibility benefits. The Final Rule also improperly interferes with state authority to implement the Regional Haze Program, in direct violation of the cooperative federalism structure of the CAA. As was recently explained in a letter to Administrator Pruitt from the Attorneys General for 19 states, “the primary regulators of the environment are the States and local governments.”² EPA should reconsider and eliminate these provisions of the Final Rule to restore the proper balance of state and federal authority, as well as to make the Rule consistent with the CAA and prior EPA regulations and effectuate recent Executive Orders.

¹ 82 Fed. Reg. 3,078 (Jan. 10, 2017) (“Final Rule”).

² Letter to Hon. Scott Pruitt, Administrator, U.S. EPA, re: Request to reexamine delegation of certain environmental regulation authority to the States in accordance with the express terms of the Clean Air and Water Acts (Mar. 7, 2017).

I. INTRODUCTION

A. Description of Petitioners

The Petitioners are electric generating companies that own and/or operate power plants subject to the Regional Haze Program and are directly affected by the Final Rule.

SPS is a wholly owned subsidiary of Xcel Energy Inc., a utility holding company headquartered in Minneapolis, Minnesota. Xcel Energy Inc.'s operating companies own 75 generating facilities with approximately 16,744 megawatts of electric generating capacity and 20,053 miles of transmission lines, with SPS owning nine generating plants with approximately 4,446 megawatts of electric generating capacity and 6,839 miles of transmission lines. Xcel Energy Inc.'s operating companies, including SPS, serve approximately 3.5 million electricity customers across Colorado, Michigan, Minnesota, New Mexico, North Dakota, South Dakota, Texas and Wisconsin, with SPS serving approximately 388,000 electric customers in a 52,000 square mile area of the Texas Panhandle and eastern and southern New Mexico. Xcel Energy Inc. has approximately 12,000 employees.

Entergy is an integrated energy company engaged primarily in electric power production and retail distribution operations. Entergy owns and operates power plants with approximately 30,000 megawatts of electric generating capacity. Entergy delivers electricity to 2.8 million utility customers in Arkansas, Louisiana, Mississippi, and Texas and owns and operates wholesale electricity generating units in Massachusetts, Michigan, and New York. Entergy has more than 13,000 employees.

Cleco is a regulated utility company headquartered in Pineville, Louisiana. Cleco owns nine generating units with a total nameplate capacity of 3,310 megawatts, 11,931 miles of distribution lines and 1,305 miles of transmission lines. Cleco delivers electricity to approximately 287,000 customers in Louisiana through its retail business, and supplies wholesale power in Louisiana and Mississippi. Cleco is a wholly owned subsidiary of Cleco Corporate Holdings LLC, a utility holding company headquartered in Pineville, Louisiana. Cleco Corporate Holdings LLC has approximately 1,200 employees.

B. Background

Section 169A of the CAA establishes a national goal of preventing future visibility impairment (*i.e.*, “regional haze”) and remedying existing visibility impairment caused by manmade air pollution in certain national parks, wilderness areas, and monuments (collectively defined as “Class I areas”).³ To implement this goal, states must adopt State Implementation Plans (“SIPs”) for phased 10-year planning periods that (1) require certain major stationary sources to meet emission limits based on the installation of “best available retrofit technology”

³ 42 U.S.C. § 7491(a)(1).

“BART”),⁴ and (2) include a long-term strategy for the state to make “reasonable progress” towards the national goal of attaining natural visibility conditions by 2064.⁵ The long-term strategy consists of “such emission limits, schedules of compliance and other measures as may be necessary” for meeting reasonable progress goals.⁶

In setting a reasonable progress goal, the CAA requires states to consider four factors: “the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements.”⁷ EPA further specifies that the reasonable progress goal “must provide for an improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period.”⁸ EPA has explained that reasonable progress goals are “interim goals that represent incremental visibility improvement over time toward the goal of natural background conditions.”⁹

EPA took a two-phased approach in establishing the Regional Haze Program to satisfy the mandate of CAA Section 169A. In the first phase, EPA addressed impairment of visibility in Class I areas that was “reasonably attributable” to a specific source or smaller group of sources.¹⁰ This “reasonably attributable visibility impairment” (“RAVI”) program also addressed potential visibility impacts from new and modified major sources already subject to New Source Review permitting requirements.¹¹ In the second phase, beginning with EPA’s 1999 Regional Haze Rule,¹² EPA addressed regional haze in Class I areas through a regional planning approach. This second phase targets visibility impairment that is not reasonably attributable to a single source or small, defined group of sources, but instead is produced by emissions from a wide array of sources over a broad geographic area.

⁴ BART is defined as “an emission limitation based on the degree of reduction achievable through the application of the best system of continuous emission reduction.” 40 C.F.R. § 51.301.

⁵ 42 U.S.C. § 7491(b)(2).

¹¹ *Id.*

¹² 64 Fed. Reg. 35,714, 35,731 (July 1, 1999). EPA revised the Regional Haze Rule in 2005. 70 Fed. Reg. 39,104 (July 6, 2005).

The Final Rule revises provisions of both the RAVI and Regional Haze Programs.¹³ According to EPA, the revisions remove older provisions that have been superseded by subsequent developments and clarify certain provisions to ensure consistent understanding of requirements as states prepare their Regional Haze SIPs for the second implementation period. Most notably, the Final Rule (1) “clarifies” the relationship between reasonable progress goals and long-term strategies; and (2) modifies and expands the RAVI program.

II. REQUEST FOR RECONSIDERATION

EPA should grant reconsideration because certain provisions of the Final Rule contradict the CAA and EPA’s previous regulations, undermine the principles of cooperative federalism, and impose excessive costs with no corresponding visibility benefits. Federal agencies have inherent authority to reconsider their past decisions and to revise, replace or repeal a decision to the extent permitted by law and supported by a reasoned explanation. *FCC v. Fox Television Stations, Inc.*, 556 U.S. 502, 515 (2009); *Motor Vehicle Mfrs. Ass’n of U.S. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 42 (1983).

Reconsideration of a rulemaking is “well within an agency’s discretion” when it is based “on a reevaluation of which policy would be better in light of the facts.” *Nat’l Ass’n of Home Builders v. EPA*, 682 F.3d 1032, 1038, 1042 (D.C. Cir. 2012) (citing *Fox*, 556 U.S. at 514-15). The agency need not demonstrate that the reasons for the new policy are better than the reasons for the old one; rather, “it suffices that the new policy is permissible under the statute, that there are good reasons for it, and that the agency believes it to be better.” *Fox*, 556 U.S. at 515 (emphasis omitted). A new Presidential Administration is a valid reason for conducting such a reevaluation of the best policy approach. *Motor Vehicle Mfrs. Ass’n*, 463 U.S. at 59 (1983) (Rehnquist, J., concurring in part and dissenting in part) (“A change in administration brought about by the people casting their votes is a perfectly reasonable basis for an executive agency’s reappraisal of the costs and benefits of its programs and regulations.”). EPA recently exercised this authority when announcing its intent to reconsider the Clean Water Rule.¹⁴

A. EPA Should Eliminate Provisions “Clarifying” the Relationship Between Long-Term Strategies and Reasonable Progress Goals.

The Final Rule revises certain regulatory provisions to “clarify the relationship between long-term strategies and reasonable progress goals.”¹⁵ These revisions include adding provisions (1) requiring states to select emission control measures for long-term strategies *before* calculating reasonable progress goals;¹⁶ and (2) providing that a state, when developing its long-term strategy and considering the time necessary for compliance, “may not reject a control measure because it cannot be installed or become operational until after the end of the

¹³ 40 C.F.R. Pts. 51-52.

¹⁴ 82 Fed. Reg. 12,532 (Mar. 6, 2017).

¹⁵ 82 Fed. Reg. at 3,078.

¹⁶ See 40 C.F.R. § 51.308(f)(2)(i).

implementation period.”¹⁷ These modifications should be eliminated because they undermine the CAA’s intent to achieve gradual and steady improvement in visibility in Class I areas over a 60-year period, as well as limit state authority and increase costs for affected sources without any corresponding visibility benefit.

1. The “Clarifications” Improperly Require Assessment of Reasonable Progress Controls *Before* States Set Reasonable Progress Goals.

EPA’s “clarification” turns the statutory scheme on its head by requiring states to identify reasonable progress controls to be included in long-term strategies before they establish their reasonable progress goals, contradicting both the CAA and the Agency’s own regulations. The CAA requires states to set reasonable progress goals by considering four factors: (1) the costs of compliance; (2) the time necessary for compliance; (3) the energy and nonair quality environmental impacts of compliance; and (4) the remaining useful life of any existing source subject to such requirements.¹⁸ The Act then permits states to impose emission reduction requirements in their long term strategies *only* to the extent *necessary* to achieve reasonable progress.¹⁹ Accordingly, Congress directed that states *first* set reasonable progress goals (considering the four statutory factors) and *second*, develop long-term strategies to achieve the reasonable progress goals. As EPA itself has explained, a state’s long-term strategy is inextricably linked to the reasonable progress goals because the long-term strategy “must include enforceable emission limitations, compliance schedules, and other measures *as necessary to achieve the reasonable progress goals....*”²⁰

The Final Rule effectively reverses this process, violating the statutory mandate that reasonable progress controls be imposed *as necessary* to meet reasonable progress goals. First, when developing long-term strategies, the Final Rule requires states to “evaluate and determine the emission reduction measures that are necessary to make reasonable progress by considering the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment.”²¹ Second, the Final Rule requires states to establish reasonable progress goals that reflect the visibility conditions projected to be achieved by the end of the applicable implementation period as a result of the emission reductions measures identified in the first step.²² Taken together, these new provisions require states to identify reasonable progress controls to include in their long-term strategies *before* establishing their reasonable progress goals.

¹⁷ 82 Fed. Reg. at 3,089; *see also* 40 C.F.R. § 51.308(f)(2)(i).

¹⁸ 42 U.S.C. § 7491(g)(1).

¹⁹ *See* 42 U.S.C. § 7491(b)(2) (long term strategies must “contain such emission limits ... *as may be necessary* to make reasonable progress”) (emphasis added).

²⁰ *See* 82 Fed. Reg. at 3,084 (quoting 40 C.F.R. § 51.308(d)(3)) (emphasis added).

²¹ 40 C.F.R. § 51.308(f)(2)(i).

²² *Id.* § 51.308(f)(3)(i).

Not only does this change in sequencing violate the CAA, EPA's new approach leads to the absurd result that states may be required to impose emission control requirements that *are not necessary* to make reasonable progress toward the national visibility goal. In other words, states may be forced to require controls where actual visibility in the Class I area already is better than the reasonable progress goals that would be established based on an evaluation of the four statutory factors. This is the case in Arkansas and Texas, where EPA applied this new sequencing in Federal Implementation Plans ("FIPs") for those states. In both cases, EPA imposed burdensome and expensive emission control requirements in long-term strategies even though visibility in both states already has surpassed EPA's final reasonable progress goals for the first planning period.²³ The outcome in Arkansas is particularly arbitrary, as the Class I areas in that state already have surpassed the uniform rate of progress ("URP"), or glidepath, for the planning period.²⁴

This is a plainly arbitrary outcome that far exceeds what the CAA envisions. Under the Act, a state may impose emission reduction requirements only to the extent *necessary* to achieve reasonable progress towards natural visibility levels.²⁵ But EPA's new approach requires individual source controls without assessing whether those controls are necessary to address visibility impairment. If an evaluation of the four statutory factors identifies control measures, the Final Rule *requires* that states establish reasonable progress goals based on the imposition of such control measures, regardless of whether the controls result in reasonable visibility improvements in a Class I area. As a result, because the reasonable progress goal assumes the installation of these control measures, states are effectively required to mandate that individual sources impose these controls.

The practical effect of this approach will give undue weight to the cost of compliance factor. In recent Regional Haze FIPs, which applied EPA's new interpretation even before EPA codified it in the Final Rule, EPA deemed a control to be "reasonable" for a state's long-term strategy if it is cost-effective. For example, in the Arkansas Regional Haze FIP, EPA required controls on Entergy's Independence Plant in part because EPA concluded that imposing controls on the plant would be cost-effective.²⁶ EPA gave no consideration to whether the controls and resulting emissions reductions would improve visibility in any Class I area and, in fact, recognized that controls would not be necessary for Arkansas Class I areas to meet their URPs.²⁷ This is problematic because it does not consider the costs in relation to visibility improvement,

²³ See Brief of Entergy, et al. at 34-35, *Arkansas v. EPA*, No. 16-4270 (8th Cir. Feb. 17, 2017); Brief of State of Arkansas at 34-38, *Arkansas v. EPA*, No. 16-4270 (8th Cir. Feb. 17, 2017); *Texas v. EPA*, 829 F.3d 405, 427 (5th Cir. 2016).

²⁴ See Brief of Entergy, et al. at 34-35, *Arkansas v. EPA*, No. 16-4270 (8th Cir. Feb. 17, 2017); Brief of State of Arkansas at 34-38, *Arkansas v. EPA*, No. 16-4270 (8th Cir. Feb. 17, 2017).

²⁵ See 42 U.S.C. § 7491(b)(2) (implementation plans must "contain such emission limits . . . as may be *necessary* to make reasonable progress") (emphasis added).

²⁶ See 80 Fed. Reg. 18,944, 18,991-92 (Apr. 8, 2015).

²⁷ See 80 Fed. Reg. at 18,992.

or lack thereof. Controls, regardless of their cost-effectiveness, should be required only when they are *necessary* for a state to achieve reasonable progress toward the national visibility goal.

Implementation of the new approach also will illegally proscribe states' authority in setting their reasonable progress goals and developing their long-term strategies. In effect, the Final Rule requires EPA to reject SIPs if the state determines that controls are unnecessary because they would achieve only minute visibility improvements. It also requires EPA to reject SIPs if the state decides not to evaluate any sources for reasonable progress controls because its Class I areas already are meeting or exceeding the URP; instead, states will be forced to select specific sources for evaluation of emission controls. Because such determinations are within the states' purview pursuant to the CAA, the Final Rule unlawfully takes authority away from the states and gives it to EPA. Such arrogation of authority violates the cooperative federalism principles underlying the CAA.²⁸ The Act limits EPA to a deferential role, under which the Agency must defer to states' determination of their reasonable progress goals so long as they comply with the Act.²⁹

2. The “Clarifications” Improperly Sever the Link Between Reasonable Progress Controls and Planning Periods.

The Final Rule severs the link between reasonable progress controls in a state's long-term strategy and the 10-year planning periods on which the Regional Haze Program is based. States' authority to consider planning periods when developing long-term strategies under the Final Rule is explicitly constrained. Specifically, the Final Rule modifies the Regional Haze regulations to explicitly provide that if a state, in selecting control measures for a long-term strategy, “concludes that a control measure cannot reasonably be installed and become operational until after the end of the implementation period, the State may not consider this fact in determining whether the measure is necessary to make reasonable progress.”³⁰ This revision means that states are required to impose reasonable progress controls without any nexus to an implementation period—that is, regardless of whether or not the control will help meet reasonable progress goals during the relevant 10-year planning period.

This directly conflicts with both the statute and the regulatory requirements in § 51.308. First, the Regional Haze regulations still require states to consider the relevant planning period when setting reasonable progress goals: when setting goals, states must consider “the [URP] and

²⁸ See 42 U.S.C. § 7401(a)(3); § 7407(a).

²⁹ *Texas v. EPA*, 829 F.3d 405, 428 (5th Cir. 2016) (citing 42 U.S.C. § 7410(k)(3) (EPA “shall approve” a state implementation plan that satisfies the requirements of the Act)); *Luminant Generation Co. v. EPA*, 675 F.3d 917, 921 (5th Cir. 2012) (“With regard to implementation, the Act confines the EPA to the ministerial function of reviewing SIPs for consistency with the Act’s requirements”); *Michigan v. EPA*, 268 F.3d 1075, 1083 (D.C. Cir. 2001) (“[T]he Act intended to create an overarching federal role in air pollution control policy, . . . but that overarching role is in setting standards, not in implementation.”).

³⁰ 40 C.F.R. § 51.308(f)(2)(i); see also 82 Fed. Reg. at 3,089 (a state “may not reject a control measure because it cannot be installed or become operational *until after the end of the implementation period.*”) (emphasis added).

the emission reduction measures needed to achieve it *for the period covered by the implementation plan.*”³¹ Second, § 51.308(d)(3) mandates that long-term strategies include measures “as necessary to achieve the reasonable progress goals.”³² The regulatory text further specifies that reasonable progress goals must consider the emission reduction measures needed to achieve the uniform rate of progress “for the period covered by the implementation plan.”³³ Even in the Final Rule, EPA itself emphasized that the reasonable progress goals do not include emission reductions that would occur only *after* the end of the relevant planning period.³⁴ It is simply illogical, then, that a control measure that could not be implemented until after the planning period would nonetheless be deemed necessary to achieve reasonable progress for that same period.

EPA should not require states to evaluate and impose control measures that are completely divorced from the planning period at issue. This undermines the purpose of the 10-year planning period. Planning periods are mandated by the statute,³⁵ and indicate Congress’s intent to establish a program that takes a gradual approach toward the national goal of eliminating visibility impairment. EPA itself observed this when first promulgating the Regional Haze Rule, providing the states with 60 years to reach natural visibility conditions at Class I areas because, in the long term, facilities built in the latter part of the 20th century will retire and/or be replaced by more fuel-efficient facilities, and innovations in emissions control technologies and renewable energy will allow new plants to meet lower emissions rates.³⁶ EPA also has explained that states “should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for [the state] to defer reductions to later planning periods in order to maintain a consistent glidepath toward the long-term goal.”³⁷

EPA’s approach in the Final Rule contradicts this statutory and regulatory scheme and will force states to mandate emissions controls even if it would be reasonable to defer them to later planning periods.. It also imposes unnecessary costs on regulated sources, which may be required to install costly new control measures without any corresponding benefit in visibility improvement that would help achieve reasonable progress during the relevant planning period.

³¹ 40 C.F.R. § 51.308(d)(1)(i)(B) (emphasis added). This requirement existed in the prior version of the regulation. *See* 40 C.F.R. § 51.308(d)(1)(i)(B) (2012). The Final Rule did not modify this requirement. *See* 40 C.F.R. § 51.308(d)(1)(i)(B) (2017); *see also* 82 Fed. Reg. at 3,089.

³⁷ Reasonable Progress Guidance at 1-4.

B. EPA Should Eliminate the RAVI Program, Which Is Unnecessary and Impedes State Authority.

EPA should eliminate the outdated RAVI program from the Regional Haze regulations because it serves no purpose in light of the subsequent implementation of the Regional Haze Program and because it unlawfully intrudes upon states' authority under the CAA. In the Final Rule, EPA not only retained the RAVI program but expanded the program's scope to (1) include all states for the first time;³⁸ (2) allow federal land managers ("FLMs") to certify RAVI in states where the source or sources are located, even if that state does not contain the Class I area where the visibility impairment occurred;³⁹ and (3) cover both BART-eligible and non-BART-eligible sources.⁴⁰ The Final Rule also alters the federal-state relationship by (1) giving FLMs authority to identify (as opposed to suggest) the source or small group of sources responsible for RAVI, thereby triggering mandatory requirements for the state, including the requirement to submit a SIP revision,⁴¹ and (2) revising the definition of "reasonably attributable" to "make clear that a state does not have complete discretion to determine what techniques are appropriate for attributing visibility impairment to specific sources."⁴²

As noted above, EPA took a two-phased approach in establishing the Regional Haze Program. In the first phase, EPA established the RAVI program to address impairment of visibility in Class I areas that was "reasonably attributable" to a specific source or smaller group of sources.⁴³ The RAVI regulations sought to address "plume blight," which is "smoke, dust, colored gas plumes, or layered haze emitted from stacks which obscure the sky or horizon and are relatable to a single source or a small group of sources."⁴⁴ EPA "explicitly deferred action on regional haze," defined as "visibility-impairing pollution that is caused by the emission of air pollutants *from numerous sources located over a wide geographic area.*"⁴⁵ In the second phase, EPA addressed regional haze in Class I areas through a regional planning approach with the promulgation of the Regional Haze Rule. This second phase targets visibility impairment that is not reasonably attributable to a single source or small, defined group of sources, but instead is

³⁸ 82 Fed. Reg. at 3,112; 40 C.F.R. § 51.300.

³⁹ See 40 C.F.R. § 51.302.

⁴⁰ See 82 Fed. Reg. at 3,112-13; see also 40 C.F.R. § 51.302(a)-(c). Under the revised RAVI program, a state must revise its Regional Haze SIP to include a reasonable progress control determination for a particular source or small group of sources upon receipt of a RAVI certification of impairment, regardless of whether or not the source is BART-eligible. See 40 C.F.R. § 51.302(b).

⁴¹ See 40 C.F.R. § 51.302(a)-(c).

⁴² 82 Fed. Reg. at 3,112; 40 C.F.R. § 51.301.

⁴³ See RAVI Regulation, 45 Fed. Reg. 80,084, 80,085-86 (Dec. 2, 1980); 40 C.F.R. § 51.300-307.

⁴⁴ RAVI Regulation, 45 Fed. Reg. at 80,085.

⁴⁵ U.S. EPA, Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period, at 5-6 (July 2016) (emphasis added) Docket No. EPA-HQ-OAR-2016-0289-0020.

produced by emissions from a wide array of sources over a broad geographic area. This expanded the scope of visibility improvement requirements to many more sources.

The Regional Haze Program has, by design, subsumed the RAVI program and rendered it unnecessary. RAVI was designed as a placeholder until techniques for assessing regional haze, particularly from multiple sources, improved sufficiently for EPA to establish a comprehensive program. EPA established this comprehensive program in the 1999 Regional Haze Rule which “fulfill[ed] EPA’s responsibility under section 169A, pending since 1980, to put in place a national regulatory program that addresses *both* reasonably attributable *and* regional haze visibility impairment.”⁴⁶ Specifically, the evaluation of sources for reasonable progress controls under the Regional Haze Program will capture sources that otherwise might be targeted by RAVI.

Instead of eliminating the RAVI program in recognition of the fact that it is unnecessary in light of the Regional Haze Program, the Final Rule expands the RAVI program beyond its original intent, thereby increasing its redundancy with the Regional Haze Program. *First*, EPA’s assertion that RAVI is applicable to any source, even if it is not BART-eligible,⁴⁷ goes against EPA’s own regulations and guidance, which state that RAVI is focused on BART-eligible sources.⁴⁸ The Final Rule also suggests that an FLM certification of RAVI would reopen the BART determination process for sources that already were eliminated from BART requirements because their emissions were not determined to be causing or contributing to visibility impairment in any Class I area. This makes no sense. If a source was deemed not subject to BART because it is not causing or contributing to visibility impairment, the FLM certification would necessarily be for *imperceptible* visibility impairment and not the visibility impairment intended to be addressed by the RAVI program. Further, the reasonable progress analysis under the Regional Haze Program already provides an avenue to address non-BART sources. The new RAVI provisions simply provide a mechanism by which the federal government can supplant state determinations on how to address these sources.

Second, the Final Rule’s requirement for FLMs to issue RAVI certifications to states *outside* of the state with the affected Class I area⁴⁹ effectively alters the RAVI program from one that addresses *intrastate* haze from a source or small group of sources to one addressing *interstate* haze from regional sources. Rather than streamlining the RAVI and Regional Haze programs, this change increases the overlap between the two programs. It also is unnecessary

⁴⁷ 82 Fed. Reg. at 3,115.

⁴⁸ See U.S. EPA, Additional Regional Haze Questions, at 16-17 (Sept. 27, 2006) Docket No. EPA-HQ-OAR-2016-0289-0014; U.S. EPA, Guidelines for Determining Best Available Retrofit Technology for Coal-Fired Power Plants and Other Existing Stationary Facilities, at 3-6, 6 (Nov. 1980) EPA-450/3-80-009b (“Once the impact of the existing stationary facility on visibility is identified as being reasonably attributable to that source, the State must conduct an analysis to determine BART for that particular existing stationary facility.”).

⁴⁹ See 40 C.F.R. § 51.302.

because the Regional Haze Program already establishes a comprehensive program for addressing haze from sources outside of a state in which an affected Class I area is located.

Third, EPA suggests that RAVI certifications could be based on modeling alone.⁵⁰ Modeled visibility impairment is not what the RAVI program was designed to address and makes the RAVI program even more duplicative of the Regional Haze Program. Modeling that simulates an event that might occur is far from the “visual observation” called for in the original definition of “reasonably attributable.”⁵¹ It also strays far from the original intent of RAVI to address plume blight. Modeling would not demonstrate any “smoke,” “dust,” “colored gas plumes,” or “layered haze,” or whether such events “obscure the sky or horizon.”⁵² Instead, the use of modeling would make RAVI indistinguishable from how states are directed to determine whether sources are causing or contributing to regional haze.

Finally, the revised RAVI program improperly alters the federal-state relationship. In developing a “cooperative federalism” framework under the CAA, Congress purposely limited the federal government’s authority by creating a statute in which “air pollution prevention . . . and air pollution control . . . is the primary responsibility of States and local governments.”⁵³ The Final Rule undermines this intent. For instance, the revisions giving FLMs the authority to identify (as opposed to merely suggest, as under the prior regulation) the source or small group of sources responsible for RAVI shifts discretion and authority from states to FLMs.⁵⁴ While FLMs may be able to identify RAVI, they have no particular expertise in identifying which sources are causing RAVI. States are more appropriate authorities for this identification.

EPA should eliminate the RAVI provisions from its regulations. There are no sources evading the Regional Haze Program that warrant retaining the RAVI program as a backstop. It makes no sense to continue to impose RAVI when reasonable progress planning addresses emissions from sources that would have been subject to RAVI and imposes controls for visibility impairment far below what would warrant controls under RAVI. It also is not necessary to preserve the RAVI program to provide FLMs the ability to work with states or EPA to address visibility concerns given that the Regional Haze Program has existing mechanisms for engaging with FLMs in developing implementation plans. In light of this redundancy, the RAVI

⁵⁰ 82 Fed. Reg. at 3,113 (explaining changes to definition of “reasonably attributable” in 40 C.F.R. § 51.301). In the RAVI regulations, EPA made it clear that RAVI certifications were to be based on *observed* visibility impairment (in evaluating FLM certification, the state needs to review the specific documentation of visibility conditions contained in the certification, which “should include information regarding the type of impairment (*i.e.*, coherent plume or layered haze)[,] the location of both the observer and the observed impairment, the meteorological conditions when the impairment was observed, and the time(s) of day or year of occurrence.”). 52 Fed. Reg. 7802, 7804 (Mar. 12, 1987).

⁵¹ See 40 C.F.R. § 51.301.

⁵² See RAVI Regulation, 45 Fed. Reg. at 80,085.

⁵³ 42 U.S.C. § 7401(a)(3); see also 42 U.S.C. § 7407(a) (“Each State shall have the primary responsibility for assuring air quality within the entire geographic area comprising such State”); see also *Texas v. EPA*, 829 F.3d at 411 (EPA’s role in reviewing SIPs is “ministerial”).

⁵⁴ See 40 C.F.R. § 51.302(a)-(c).

program's costs cannot justify its benefits. Further, the obligation for states to develop SIP revisions in response to a RAVI certification could strain states' limited resources.

C. Reconsideration Is Appropriate in Light of Recent Executive Orders.

EPA should grant reconsideration of the Final Rule in light of recent executive orders directing federal agencies to reduce regulatory costs and/or eliminate or modify regulations that impose unnecessary costs or burdens. Specifically, President Trump issued an executive order on January 30, 2017, entitled "*Reducing Regulation and Controlling Costs*,"⁵⁵ which sets a "zero sum" cost requirement for new regulations, under which the total incremental cost of all new regulations to be finalized in fiscal year 2017 shall be "no greater than zero," unless otherwise required by law or directed by the White House Office of Management and Budget.⁵⁶ The Order requires agencies to offset "any new incremental costs associated with new regulations . . . by the elimination of existing costs associated with at least two prior regulations."⁵⁷ President Trump issued another executive order on February 24, 2017, entitled "*Enforcing the Regulatory Reform Agenda*,"⁵⁸ that directs agencies to establish Regulatory Reform Task Forces to evaluate existing regulations and recommend any which should be repealed, replaced, or modified, including those that (i) eliminate jobs or inhibit job creation; (ii) are outdated, unnecessary, or ineffective, or (iii) impose costs that exceed benefits.⁵⁹

As discussed in this Petition, certain provisions of the Final Rule impose unnecessary costs and burdens. Specifically, EPA's new interpretation of "reasonable progress" requires states to impose controls on sources, even when such controls are unnecessary to achieve reasonable progress during the planning period covered by the SIP. In states where the URP or reasonable progress goals already have been attained without reasonable progress controls, no additional "benefit" in light of the purposes of the Regional Haze Program can be gained through the imposition of such controls. Additionally, the RAVI program adds redundant and potentially costly requirements to the already comprehensive Regional Haze Program. EPA should eliminate those portions of the Final Rule that impose costs with no benefits and all of the RAVI program provisions to further the Agency's efforts to effectuate these Executive Orders. Repealing these provisions also would assist EPA in complying with the One In, Two Out Order, because eliminating program costs will help the Agency offset new mandatory environmental regulations.

Re: Petition for Reconsideration by Southwestern Public Service Company, Entergy Services Inc. and Cleco Power LLC of the final rule titled *Protection of Visibility: Amendments to Requirements for State Plans*, 82 FR 3078, published on January 10, 2017

Dear Ms. Jezouit and Ms. Mallick:

The U.S. Environmental Protection Agency has reviewed the petitions for reconsideration of the final rule titled *Protection of Visibility: Amendments to Requirements for State Plans* published at 82 FR 3078 (January 10, 2017), including the petition submitted by Southwestern Public Service Company, Entergy Services Inc. and Cleco Power LLC. The EPA is not at this time acting on the petitions for reconsideration. We have, however, considered the issues therein and decided to revisit aspects of the 2017 Regional Haze Rule under our inherent rulemaking authority.¹ We intend to commence a notice-and-comment rulemaking in which we will address portions of the rule, including but not limited to the Reasonably Attributable Visibility Impairment provisions, the provisions regarding Federal Land Manager consultation and any other elements of the rule we may identify for additional consideration. Furthermore, we plan to finalize one or more EPA guidance documents for regional haze State Implementation Plan revisions due in 2021. Such guidance may also address some or all of the issues raised in the petitions for reconsideration.

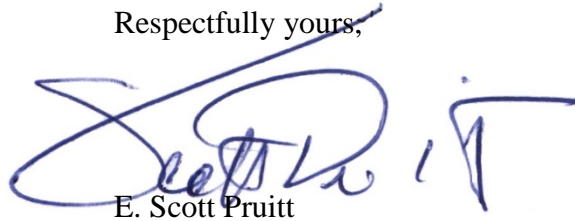

We intend to prepare a notice of proposed rulemaking that will provide Southwestern Public Service Company, Entergy Services Inc., Cleco Power LLC and the public an opportunity to comment on the issues identified above, as well as any other aspects of the rule we believe will

¹ *Trujillo v. Gen. Elec. Co.*, 621 F.2d 1084, 1086 (10th Cir. 1980) (“Administrative Agencies have an inherent authority to reconsider their own decisions, since the power to decide in the first instance carries with it the power to reconsider.”); see also *United Gas Improvement Co. v. Callery Properties Inc.*, 382 U.S. 223, 229 (1965); *Mazaleski v. Treusdell*, 562 F.2d 701, 720 (D.C. Cir. 1977).

benefit from further public input. We appreciate your input and your interest in this matter. The decision to revisit the rule is not a determination on the merits of the issues raised in the above-captioned petition for reconsideration.

If you have any questions regarding this action, please contact Amanda M. Gunasekara in the Office of Air and Radiation at (202) 564-7404 or gunasekara.mandy@epa.gov.

Respectfully yours,

1. EXECUTIVE SUMMARY

This report is provided to address information related to visibility impacts attributable to the use of low-sulfur coal at the Independence Steam Electric Station (Independence) that is missing from the Arkansas Department of Environmental Quality's October 2017 SIP proposal. It is important for the ADEQ to consider visibility modeling results for all "control" scenarios, including the use of low sulfur coal. Entergy Arkansas, Inc. (EAI) and Trinity Consultants (Trinity) want to ensure that the use of low sulfur coal as a "control" scenario is not viewed as resulting in no visibility improvement.

This brief report presents the modeling inputs, methodologies, and results related to the Independence low-sulfur coal scenario. As documented in this report, using low-sulfur coal at Independence Units 1 and 2 is predicted to achieve five (5) to 15 percent improvement in visibility at the two Class I areas in Arkansas and the two Class I areas in Missouri.

2. BACKGROUND

Information regarding modeled visibility improvement due to the use of low-sulfur coal (LSC) at the Entergy Arkansas, Inc. (EAI) Independence Steam Electric Station (Independence) is missing from the October 2017 State of Arkansas *Revisions to the Arkansas State Implementation Plan – Regional Haze SIP Revision for 2008-2018 Planning Period* (the proposed SIP).¹ The SIP, at paragraph V.C.6, states: “Because Entergy Independence frequently achieves less than or equal to the 0.6 lb/MMBtu emission rate associated with LSC, **ADEQ has not modeled visibility impacts for the LSC scenario**” (emphasis added). As described in comments filed by EAI on the proposed SIP, the premise of ADEQ’s statement – that low-sulfur coal is currently being used at Independence that would allow the units to meet an emission rate of 0.6 lb/MMBtu – is flawed. Therefore, EAI and Trinity Consultants (Trinity) are providing this report, which shows the modeled visibility improvement for the LSC scenario, for ADEQ’s consideration.

¹ State of Arkansas Revisions to the Arkansas State Implementation Plan – Regional Haze SIP Revision for 2008-2018 Planning Period, Arkansas Department of Environmental Quality, Office of Air Quality, Policy and Planning Branch, October 2017. (<https://www.adeq.state.ar.us/air/planning/sip/pdfs/regional-haze/public-review-package.pdf>, accessed on December 20, 2017)

3. MODELING INPUTS AND METHODOLOGY

3.1. MODELING METHODOLOGY

Except where specifically updated as described in this report, Trinity conducted the CALPUFF² modeling for Independence using the same protocol, methodologies, and inputs used for EAI's White Bluff Five Factor Analyses submitted on October 15, 2013, and revised on August 18, 2017. This CALPUFF modeling differs from the modeling conducted by EPA in support of the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas (the "proposed FIP")³ in several ways, as summarized below:

- EAI and Trinity determined that EPA's modeled location of Independence was incorrect – off by approximately 110 kilometers (km) in the CALPUFF/CALMET-required Lambert Conformal Conic (LCC) map projection. The modeling presented in this report accurately represents the location of the Independence units.
- Because of the location error, EPA's modeling also used incorrect base elevations. The modeling presented in this report corrects this error.
- The modeling presented in this report followed the Arkansas Best Available Retrofit Technology ("BART")⁴ Modeling Protocol for the following parameters instead of the CALPUFF-default values:
 - Wet deposition liquid precipitation scavenging coefficient for SO₂: The ADEQ BART Modeling Protocol Table G-12 lists 3.21E-05 s⁻¹ as both the default and the selected value.⁵ The default in the CALPUFF manual is 3.0E-05 s⁻¹, which is the value utilized by EPA.⁶
 - Monthly ozone values used to fill in missing data: ADEQ BART Modeling Protocol Table G-13 lists 80 ppb as the default and 40 ppb as the selected value. The default in the CALPUFF manual is 80 ppb, which is the value utilized by EPA.

3.2. MODELED SCENARIOS AND EMISSION RATES

To determine the visibility impact, in delta deciviews (Δdv), of a control device using CALPUFF modeling, two modeling scenarios are needed: a baseline scenario and a control scenario. In this case, the control scenario will represent the use of low-sulfur coal (LSC).

² Trinity and EAI assert that CALPUFF is not the most appropriate model for estimating visibility impacts. Due to its numerous inherent limitations (e.g., limited chemistry mechanism, distance limitations, blanket background ammonia values, etc.), CALPUFF does not yield reliable results. Furthermore, CALPUFF is no longer an EPA-preferred model, which further indicates CALPUFF's unreliability. More advanced models like the Comprehensive Air Quality Model with Extensions (CAMx)—if processed appropriately—can yield more reliable characterizations of visibility impairment. Nevertheless (without waiver), CALPUFF modeling is used for the purpose of this report. CAMx modeling could not be completed within the comment period for the proposed SIP.

³ 80 FR 18,944, Proposed Federal Implementation Plan to address certain regional haze and visibility transport requirements for the State of Arkansas (April 8, 2015).

⁴ Independence is not subject to BART requirements or BART-related modeling guidance. Rather, this guidance was used for consistency with the contemporaneous BART modeling (e.g., for White Bluff).

⁵ Draft Best Available Retrofit Technology (BART) Modeling Protocol, ADEQ. June 7, 2006. Prepared by: Mary Pettyjohn, Senior Epidemiologist.

⁶ A User's Guide for the CALPUFF Dispersion Model (Version 5). January 2000. Prepared by: Earth Tech, Inc.

The modeled baseline emission rates for each unit are based on the maximum daily average emission rates during 2011-2013. The modeled nitrogen oxides (NO_x) and sulfur dioxide (SO₂) emission rates for Unit 1 and Unit 2 are from the data available in the Clean Air Markets Database (CAMD). The modeled particulate matter⁷ (PM₁₀) emission rates for Unit 1 and Unit 2 are based on emission factors from AP-42 for filterable PM₁₀ and condensable PM (with a 99.5 percent control efficiency for ESP applied to the PM₁₀ filterable fraction) used in conjunction with the average 2011-2013 coal heating value and ash content (as a percentage of mass).⁸ The PM₁₀ emission estimate was broken down into specific PM₁₀ species – filterable coarse particulate matter (PM_c), filterable fine particulate matter (PM_f), elemental carbon (EC), inorganic condensable particulate matter (IOR CPM) as sulfates (SO₄), and organic condensable particulate matter (OR CPM), also referred to as secondary organic aerosols (SOA) – using the National Park Service (NPS) “speciation spreadsheet” for *Dry Bottom Boiler Burning Pulverized Coal using only ESP*.⁹ The emission rates for Unit 5 are estimates based on maximum daily heat input from 2011-2013 and emission factors from AP-42 for Fuel Oil Combustion.¹⁰ The PM₁₀ emission estimate was broken down into specific PM₁₀ species using the NPS “speciation spreadsheet” for *Uncontrolled Utility Residual Oil Boilers*¹¹. Table 3-1 summarizes the baseline scenario emission rates that were modeled for SO₂, NO_x, and the speciated PM₁₀ emissions.

Table 3-1. Baseline Maximum 24-hour Emission Rates (As Hourly Equivalents)

Unit	SO₂ (lb/hr)	NO_x (lb/hr)	SO₄ (lb/hr)	PM_c (lb/hr)	PM_f (lb/hr)	SOA (lb/hr)	EC (lb/hr)
1	6,095.2	3,164.7	35.8	40.2	30.9	8.9	1.2
2	6,669.4	2,478.8	35.8	40.2	30.9	8.9	1.2
5	2.4	28.5	1.3	0.6	1.6	0.2	0.1

⁷ For modeling purposes, particulate matter is the portion of total PM that has an aerodynamic diameter of 10 microns or less, i.e., PM₁₀.

⁸ AP-42, Chapter 1 External Combustion Sources, Section 1.1 Bituminous and Subbituminous Coal Combustion, Table 1.1-5, page 1.1-24 (September 1998).

⁹ The baseline speciation is based on the NPS Workbook for a Dry Bottom Boiler burning Pulverized Coal using an ESP. Based on average 2011-2013 values, the following input values were used: heating value of 8,498.33 Btu/lb, 0.26% sulfur, 5.09% ash, 8,700 MMBtu/hr heat input, and a baseline total PM₁₀ emission rate of 117.0 lb/hr for both ISES Unit 1 and Unit 2. NPS: <http://www.nature.nps.gov/air/Permits/ect/index.cfm>.

¹⁰ AP-42, Chapter 1 External Combustion Sources, Section 1.3 Fuel Oil Combustion, Table 1.3-1 and Table 1.3-2, pages 1.3-12 and 1.3-13, respectively (May 2010).

¹¹ The baseline speciation is based on the NPS Workbook for an Uncontrolled Utility Residual Oil Boiler. Based on average 2009-2011 values, the following input values were used: No 2. Fuel oil with a sulfur content of 0.01%, a heating value of 138,136 Btu/gal, a heat input of 183 MMBtu/hr, and a baseline total PM₁₀ emission rate of 3.9 lb/hr for ISES Unit 5. NPS: <http://www.nature.nps.gov/air/Permits/ect/index.cfm>.

Emission rates for the LSC scenario are the same as the baseline scenario except for the SO₂ emission rates for Units 1 and 2, which are calculated as the nominal maximum heat input capacity for each unit times the emission factor representing LSC, i.e., 8,700 million British thermal units per hour (MMBtu/hr) * 0.60 pounds of SO₂ per MMBtu (lb/MMBtu).

Table 3-2. LSC-Scenario Maximum 24-hour Emission Rates (As Hourly Equivalent)

Unit	SO₂ (lb/hr)	NO_x (lb/hr)	SO₄ (lb/hr)	PM_c (lb/hr)	PM_f (lb/hr)	SOA (lb/hr)	EC (lb/hr)
1	5,220	3,164.7	35.8	40.2	30.9	8.9	1.2
2	5,220	2,478.8	35.8	40.2	30.9	8.9	1.2
5	2.4	28.5	1.3	0.6	1.6	0.2	0.1

4. MODELING RESULTS

Trinity conducted modeling to estimate the predicted visibility impairment attributable to Independence in four Class I Areas: Caney Creek Wilderness (CACR), Upper Buffalo Wilderness (UPBU), Hercules Glades Wilderness (HEGL), and Mingo Wilderness (MING) using the CALPUFF dispersion model. Table 4-1 provides a summary of the modeled baseline scenario visibility impairment, using the 98th percentile metric, attributable to Independence based on the emission rates shown in Table 3-1.

Table 4-1. Baseline Visibility Impairment

Year ^A	CACR	UPBU	HEGL	MING
	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)
2001	2.151	1.698	1.803	1.906
2002	1.542	2.089	1.624	1.295
2003	1.864	2.071	1.889	1.354
Max.	2.151	2.089	1.889	1.906

^A Meteorological data year modeled

Table 4-2 provides a summary of the modeled LSC scenario visibility impairment, using the 98th percentile metric, attributable to Independence based on the emission rates shown in Table 3-2.

Table 4-2. LSC Scenario Visibility Impairment

Year ^A	CACR	UPBU	HEGL	MING
	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)	98 th Percentile (Δ dv)
2001	2.039	1.427	1.551	1.635
2002	1.357	1.787	1.433	1.113
2003	1.690	1.782	1.653	1.193
Max.	2.039	1.787	1.653	1.635

^A Meteorological data year modeled

Table 4-3 presents the differences between the maximum results of the two scenarios, which are the amounts of visibility improvement attributable to using LSC at Independence Units 1 and 2. These values reflect five (5) to 15 percent improvement over the baseline results.

1. INTRODUCTION

This report provides an update to the monitoring information originally provided by Entergy Arkansas, Inc. (EAI) and Trinity Consultants (Trinity) on August 7, 2015,¹ which was updated on November 15, 2016,² and September 27, 2017³. As of the September 27, 2017 update, only data for the first half of 2016 was available. Raw monitoring (“observed”) data for all months of 2016 are now available and are summarized herein. This report provide supplemental information only. The previous reports should be reviewed for explanations of how the raw data was summarized, how the deciview metric is calculated, and other background information.

Additionally, this report provides site-specific control cost estimates developed by Sargent & Lundy (S&L) for the Independence Steam Electric Station (Independence). These costs can be compared to the cost values developed by EPA for the FIP, the costs used by ADEQ for the SIP, and the costs that were presented – revised to reflect a 9-year equipment life – in the September 27, 2017 report.

2. UPDATED IMPROVE MONITORING DATA

The most recent summary of annual monitoring data available from IMPROVE for CACR and UPBU has been completed through the year 2015. As of the date of this report, non-summarized data through December 31, 2016, is available and can be used to calculate the light extinction coefficients and haze indices for 2016. Trinity obtained the non-summarized data and compiled an independent summary for 2016. The species-specific and total light extinction and haze index values for the averages of the 20 percent worst days⁴ and the 20 percent best days for 2016 are shown in Table 2-1.

Table 2-1. Independent Summary of Monitoring Data for 2016

Light Extinction Value (Mm ⁻¹)	20 Percent Worst Days Average		20 Percent Best Days Average	
	CACR	UPBU	CACR	UPBU
Sulfate	31.32	31.42	5.64	5.99
Nitrate	14.15	17.25	0.98	1.21
Organics	17.18	16.74	2.59	2.64
Carbon	3.11	3.38	0.41	0.44
Soil	2.64	2.34	0.11	0.11
Coarse PM	6.17	6.41	1.31	1.39
Sea Salt	1.07	0.76	0.08	0.07
Total Light Extinction (Mm ⁻¹)	70.08	70.12	25.31	26.32
Haze Index (dv)	19.35	19.33	9.07	9.56

Table 2-2 presents a summary of the annual-average haze index values for each year from 2002 to 2016.

⁴ The revised Regional Haze Rule published on January 10, 2017, changed the definition of the “most impaired days” but is only applicable to the second and subsequent planning periods. Accordingly, this report uses the definition of the most impaired days that is applicable to the first planning period.

Table 2-2. Summary of Annual Average Haze Index Values from 2002 through 2016

Year	20 Percent Worst Days Average		20 Percent Best Days Average	
	CACR	UPBU	CACR	UPBU
2002	27.21	26.74	11.88	12.83
2003	26.54	27.22	10.74	10.62
2004	25.34	25.58	11.11	10.74
2005	29.21	30.47	12.93	13.34
2006	25.68	25.42	12.51	13.00
2007	-- ^A	26.17	-- ^A	12.45
2008	23.70	24.60	9.24	10.49
2009	22.68	22.62	8.09	9.40
2010	22.94	-- ^A	10.76	-- ^A
2011	22.67	23.21	11.71	11.51
2012	21.49	21.56	9.54	10.31
2013	21.35	21.25	8.61	8.60
2014	20.72	20.49	8.52	8.13
2015	20.41	19.96	7.03	7.50
2016	19.35	19.33	9.07	9.56

^A Summarized data are not available for CACR for 2007 and UPBU for 2010.

Figure 2-1 and Figure 2-2 present, for CACR and UPBU, respectively, comparisons of the observed haze index values for each year of IMPROVE data, including independently summarized values from 2016, to the Uniform Rate of Progress (URP) line established for each area. The same comparisons are shown for the two Missouri Class I areas in Appendix A.

Figure 2-1. CACR Monitored Observations Compared to Uniform Rate of Progress

Figure 2-2. UPBU Monitored Observations Compared to Uniform Rate of Progress

As seen in the figures above, the actual observed visibility impairment at these Class I areas has declined sharply from 2002 through 2016 (the most recent available data). According to the monitor data, the current observed 20 percent worst days average haze index values are below the URP values for 2018 as well as the 2018 Reasonable Progress Goals (RPGs) that EPA set in the Arkansas Regional Haze Federal Implementation Plan,⁵ meaning that Arkansas has achieved more than is necessary to demonstrate reasonable progress for the first planning period. Table 2-3 presents a comparison of the 2016 observed values and the 2018 RPG values.

Table 2-3. 2016 Observed Haze Index Values Compared to 2018 URPs and RPGs

Class I Area	Observed 20 Percent Worst Days Average for 2016 (first half year)	RPG for 2018	Observed Value as % of RPG
CACR	19.35	22.47	86.1 %
UPBU	19.33	22.51	85.9 %

⁵ 81 Fed. Reg. 66,332 (September 27, 2016).

3. SITE-SPECIFIC COST INFORMATION FOR INDEPENDENCE

Site-specific control cost estimates were recently developed by Sargent & Lundy (S&L) for Dry Flue Gas Desulfurization (DFGD) at Independence. Based on these estimates, the cost of compliance is more than \$6,600/ton for Unit 1 and more than \$6,100/ton for Unit 2. S&L’s detailed report is included in Appendix B of this report, and a summary is provided in Table 3-1, below. Two sets of values are presented: “Actual” costs as estimated by S&L and “Adjusted” values based on S&L’s estimates after excluding cost items that EPA has historically claimed should not be accounted for in cost effectiveness calculations.⁶ Even using these adjusted costs, the cost of compliance would be more than \$5,000/ton for Unit 1 and more than \$4,600/ton for Unit 2.

Table 3-1. Summary of Site-Specific Control Cost Estimates – Actual and Adjusted Values

Actual Costs	Unit 1	Unit 2
Capital (\$)	491,893,500	491,893,500
Capital Recovery Factor ^A	0.1535	0.1535
Annualized Capital (\$/yr)	75,505,652	75,505,652
Annual O&M (\$/yr)	8,809,000	8,809,000
Total Annual Cost (\$/yr)	84,314,652	84,314,652
SO ₂ Emissions Reduction (ton/yr) ^B	12,608	13,655
Cost Effectiveness (\$/ton)	6,688	6,175
Adjusted Costs	Unit 1	Unit 2
Capital (\$)	355,391,500	355,391,500
Capital Recovery Factor ^A	0.1535	0.1535
Annualized Capital (\$/yr)	54,552,595	54,552,595
Annual O&M (\$/yr)	8,809,000	8,809,000
Total Annual Cost (\$/yr)	63,361,595	63,361,595
SO ₂ Emissions Reduction (ton/yr) ^B	12,608	13,655
Cost Effectiveness (\$/ton)	5,026	4,640

^A Based on a nine-year amortization period and 7 % interest.

^B EAI’s emissions reduction value differs from EPA’s value because of a difference in how the average baseline emissions were calculated. EAI simply averaged the five annual values for 2009-2013. EPA took a three-year average over the same time period after excluding the minimum and maximum values.

⁶ An example of an excluded cost is Allowance for Funds Used During Construction (AFUDC). AFUDC represents the interest expense incurred on the investment in a large capital project, such as a FGD installation, which can take several years to complete (≥ 5 years). Although interest expenses will certainly be incurred on such a project, and AFUDC is typically considered as part of the capital cost of such a project for standard accounting and rate-making purposes, EPA Region 6 has expressed concern with the inclusion of AFUDC and certain other costs. EAI disagrees and believes that determining the cost effectiveness of the control options must realistically reflect the actual cost of compliance. See EAI’s comments on the proposed FIP. Nonetheless, for completeness, this report shows a range of cost effectiveness both including AFUDC and other costs and excluding those costs.

1. PURPOSE

The purpose of this study is to estimate the total capital investment and operating and maintenance costs associated with installing dry flue gas desulfurization (FGD) technology on Independence Units 1&2.

This report documents the conceptual design and technical basis for the dry FGD cost estimate.

2. TECHNOLOGY DESCRIPTION

2.1.1. Reagent Preparation System

Lime will be supplied to the lime day bins from the long-term storage silo located in the Reagent Handling Area and supplied by the EPC Contractor. The lime day bins, located in the Reagent Preparation Area and provided by the Dry FGD System Supplier, will each have a storage capacity to supply the plant with lime reagent for 24 hours when firing 1.2 lb SO₂/mmBtu coal.

Lime from the day bin will be gravity-fed through feeders to a lime slaker, where the lime will be slaked (mixed with low pressure service water and converted from calcium oxide to calcium hydroxide slurry). The plant will have a total of two lime slaking trains (2 x 100%), each sized to process enough lime slurry to supply the entire plant. Each lime slaker will discharge to a lime slurry transfer tank, which is equipped with two lime slurry transfer pumps which will feed into the lime slurry storage tanks. The common lime slurry storage tanks will each be sized for 12 hours of storage for the entire plant when burning a 1.2 lb SO₂/mmBtu coal. The lime day bin, slaking trains, and lime slurry tanks are sized to provide the necessary reagent slurry to both units simultaneously. The lime slurry tanks are built with cross-ties such that either slurry tank can feed either the Unit 1 or Unit 2 FGD systems.

A total of four lime slurry feed pumps (two per unit), each sized for 100% flow to one unit, will pump the lime slurry from the storage tanks to the SDAs through one of 2 x 100% piping loops, and return unused slurry back to the lime slurry storage tank. The closed-loop reagent supply line requires a flow velocity between 4-10 fps to avoid any solids buildup in the piping. Because of this, the pumping requirement is higher than the actual SDA requirement and must be sufficiently greater than the slurry flow that is pumped into the absorbers to allow the returning flow to remain above 4 fps.

2.1.2. Absorbers

Three absorbers, each treating 33⅓% of the flue gas are provided for each unit. Depending on the supplier and the type of atomizer normally used, there may be one rotary atomizer per absorber with a shared spare (B&W), three rotary atomizers per absorber with one or more shared spares (Alstom, basis of the estimate), or multiple dual-fluid atomizers with 15% shared spares (Siemens). The cost estimate includes contingency to capture the possibility of any of these designs.

2.1.3. Baghouse

Each SDA will be paired with a pulse-jet baghouse with a gross air-to-cloth ratio of approximately 3.2-3.4 ft/min. The filter bags in each baghouse are cleaned by pulses of compressed air. The air compressors will be 4 x 33% for the station and are included in the scope of the baghouse supplier.

2.1.4. Byproduct Recycle System

The reaction byproducts from the absorbers will be collected in the baghouses and a portion of the collected material will be recycled. The baghouse hoppers will be emptied through air lock feeders and pneumatically conveyed to two recycle day bins located in the Byproduct Recycle Area and supplied by the Dry FGD System Supplier, which are common for both units. The air-lock feeders are installed without a spare. One recycle day bin is located in the recycle train for each unit. The common byproduct recycle day bins (one per unit) provide 8-hours of storage when burning 1.2 lb SO₂/mmBtu coal.

Each byproduct recycle day bin is equipped with two recycle slurry preparation systems. The byproduct in each recycle day bin is gravimetrically conveyed to one of two systems where the byproduct is slurried with water (cooling tower blowdown). The byproduct recycle slurry is stored in one of four plant wide recycle slurry tanks, two per unit (combined 4-hour storage capacity).

Two recycle water make-up tanks are located in the recycle area. The recycled by-product slurry will be combined with fresh lime slurry for feed to the SDA atomizers. Recycle feed slurry pumps (4 x 100%, two installed per unit) will be used to transfer the recycle slurry from the recycle slurry tanks to the atomizers. In addition, all recycle feed lines are provided in a loop configuration as with the reagent

system, with a complete redundant loop to allow unhindered operation due to any pluggage of pumps or feed piping.

2.1.5. Reagent Handling System

The basis of the estimate is delivery of lime via hopper-bottom railcars with truck unloading as a backup. In order to accommodate rail delivery to the site, a new rail spur will be constructed from the existing track on the plant site for unloading. A trackmobile car positioner will position railcars, two at a time, in the enclosed delivery shed for unloading. A vacuum pneumatic system will unload the railcars into either of the two (2) lime storage silos. The lime storage silos will be sized for supply of reagent for 14 days of storage at full load when firing 1.2 lb SO₂/mmBtu coal. Lime from the long-term storage silos will be pneumatically transferred to two lime day bins located in the Reagent Preparation Area and supplied by the Dry FGD System Supplier.

2.1.6. Byproduct Handling System

Excess FGD byproduct from the recycle system will be pneumatically conveyed to either of the two common long-term FGD byproduct storage silos. The two long-term FGD byproduct storage silos are each sized to handle the byproduct for a total of 7 days of storage when firing the 1.2 lb SO₂/mmBtu coal. The byproduct will be mixed with a small amount of fly ash and water to form a final product which contains approximately 65% FGD byproduct, 5% fly ash, and 30% water. In order to achieve this mixture, a common fly ash blending bin (7-day storage) will be located near the new byproduct silos. The wetted byproduct/fly ash mixture is then loading into dump trucks, which will deposit the FGD byproduct in a final storage location in the landfill. It is assumed that the existing landfill will have sufficient capacity to accommodate the addition of FGD byproduct. Therefore no costs were included in the capital estimate for the (existing) landfill.

2.1.7. Flue Gas Handling System

The flue gas from the existing ID fans will be ducted to the absorbers. The gases from the absorbers will be ducted to the baghouses to collect the reaction by-products and residual fly ash. Two axial booster fans (2 x 50% for each unit) will be located downstream of the absorbers and baghouse; the booster ID

fans can be provided by the Dry FGD System Supplier or the EPC Contractor. Due to the dry condition of the scrubbed flue gas, the existing stack and liners will be used for the retrofit case.

2.1.8. Electrical BOP System

In order to feed the new dry FGD and other BOP equipment, significant modifications and additions to the existing power system would be required. These include, at a minimum, installation of new auxiliary transformers, medium- and low-voltage switchgear buses, motor control centers (MCCs) and upgrades to the isolated phase tap-off buses. As a detailed conceptual design was not developed an allowance was included for the Electrical BOP Scope.

2.1.9. I&C BOP System

The dry FGD system will be integrated into the existing DCS system. The baghouse will be controlled through a PLC and the ID booster fans will be integrated into the existing DCS system. As a detailed conceptual design was not developed an allowance was included for the I&C BOP Scope.

3. APPROACH

The project capital and O&M cost estimates are based on project-specific information, including:

- An engineer-procure-construct (EPC) contracting strategy with the Dry FGD technology supplier providing the main process equipment as a complete FGD Island.
- On-site disposal of Dry FGD byproduct using new ash handling equipment. The byproduct will be collected in the new fabric filter and blended with fly ash prior to disposal.
- Reagent injection rates based on achieving an outlet SO₂ emission rate of 0.06 lb SO₂/MMBtu from a design inlet concentration of 1.20 lb SO₂/MMBtu, based on the sulfur limit in the fuel supply contracts.
 - Annual operating costs will be based on an uncontrolled SO₂ rate of 0.49 lb SO₂/MMBtu, based on the annual heat input weighted average emission from 2009 through 2013.
 - The system will be designed to control emissions to meet a permit limit of 0.06 SO₂/MMBtu, based on the required permit limits in the EPA Arkansas FIP.

- A high level conceptual system design was used as input to the Dry FGD cost estimate. The following were estimated based on previous projects and scaled for the predicted dry sorbent injection rate for Independence:
 - Auxiliary power consumption
 - Annual reagent consumption
 - Equipment Sparing and Quantities
 - BOP Allowances (Mechanical, Electrical and I&C)

The total plant capital cost estimate includes the following:

- Equipment and material
- Installation labor
- Demolition and Relocation work
- Indirect field costs and BOP engineering
- Freight on Materials
- General and Administration
- Erection contractor profit
- Engineering, Procurement and Project Services
- Spare parts/initial fills (other than reagent)
- EPC Fee

As part of this project, S&L estimated the costs for Owner's services and costs outside of the EPC contract including the following:

- Owner's Costs
- Owner's Engineer
- Construction Management Support
- Startup and Commissioning Support
- Performance Testing
- Contingency
- Escalation
- Interest During Construction

Cost Estimate 34261 provided in Attachment 1 represents the total cost to Entergy to install Dry FGD technology on both units at Independence (Unit 1 and 2) including the EPC Contract price and all additional Owner's costs and third party services.

The total unit O&M cost estimate includes the following:

- Waste disposal (Dry FGD waste)
- Reagent consumption
- Auxiliary power consumption
- Water consumption for reagent and byproduct handling
- Operating labor
- Maintenance material
- Maintenance labor

The O&M Cost Estimate and Capital Cost Estimate were developed using the assumptions and scope provided in this document. The project definition and accuracy corresponds to a study level estimate as defined in U.S.EPA's Office of Air Quality Planning and Standards (OAQPS) Control Cost Manual. The costs provided in this report are in 2017 dollars.

4. CAPITAL AND O&M COST ESTIMATE TECHNICAL BASIS

4.1. DESIGN INPUTS AND ASSUMPTIONS

The following summarizes the design inputs used as the basis for the Independence dry FGD Systems:

- Design SO₂ inlet concentration of 1.2 lb SO₂/MMBtu for equipment design, based on the current coal contract sulfur limit.
- SO₂ inlet concentration of 0.49 lb SO₂/MMBtu for annual operating costs, based on the annual heat input weighted average emission from 2009 through 2013.
- Design SO₂ outlet concentration of 0.06 lb SO₂/MMBtu.
- Annual capacity factor of 75.0% (annual average capacity factor for Independence Units 1 and 2 based on historical heat input from 2009 through 2013).
- Project duration of five years.

4.2. TOTAL INSTALLED CAPITAL INVESTMENT

The Dry FGD System Supplier will provide all of the equipment within the FGD Island. The FGD Island will include the Reagent Preparation Equipment, Absorber Area Equipment, Baghouse Area Equipment and the Byproduct Recycle Equipment. The booster ID fans could be provided by either the Dry FGD System Supplier or the EPC Contractor; the basis of this estimate is supply of the booster fans by the Dry FGD System Supplier. The EPC Contractor will provide the remaining BOP scope in order to provide a complete and operable FGD system. In addition, the EPC Contractor will install/construct the entire system including the equipment provided by the DFGD supplier. The scope of work for the cost estimate is broken out by the following areas:

4.2.1. Dry FGD Island

- a. Reagent Preparation System, common to both units:
 - Two lime day bins, 24-hours storage each
 - Two detention lime slakers at 100% capacity, each with a grit screen, gravimetric feeder
 - Two lime slurry transfer tanks
 - Four slurry transfer centrifugal pumps
 - Two lime slurry storage tanks
 - Four slurry feed centrifugal pumps
 - Cost estimate based on budgetary proposal from Alstom; the budgetary proposal is based on a design sulfur of 2.0 lb/MMBtu, cost adjustments were included in the estimate for a lower design sulfur of 1.2 lb/MMBtu. These cost adjustments were developed by estimating the differential equipment cost for the reagent preparation and waste handling equipment. The impacted equipment is identified in Section 4.5 which discusses the sulfur design basis sensitivity.
- b. Absorber Area, per unit
 - Three absorber vessels per unit, with access doors
 - Rotary atomizers, two spare atomizers included
 - Vessel material carbon steel, 1/4 in. – 5/8 in. carbon steel
 - Heating and ventilation
 - Vacuum piping
 - SDA Superstructure
 - Cost estimate based on budgetary proposal from Alstom

- c. Baghouse Area, per unit
 - New baghouse, including pulse jet cleaning system and all appurtenances
 - Cost estimate based on budgetary proposal from Alstom
- d. Byproduct Recycle System, per unit (located remotely in common location for both units)
 - One recycle silo with bin vent filter per unit, 8-hour total capacity
 - Two recycle mix tanks per unit
 - Two recycle slurry tanks per unit, with two recycle slurry centrifugal pumps per unit
 - Agitators for each tank
 - Baghouse ash handling system common to both units
 - Rotary air-lock valves from baghouse hopper outlets to pressure pneumatic conveying system (60-degree typical)
 - Pneumatic pressure blowers (8 x 33 $\frac{1}{3}$ %)
 - Cost estimate based on budgetary proposal from Alstom
- e. ID Booster Fans, per unit
 - Two approximately 5,200 hp axial booster fans per unit sized to overcome pressure drop associated with FGD and baghouse
 - Includes motors - no spare motor included
 - Cost estimate based on budgetary proposal from Alstom
 - Dampers from ID fan to booster fans (cost estimated separately, not included in Alstom budgetary proposal)
- f. Interconnecting Ductwork, per unit
 - ID fan outlet to absorber inlet ductwork and supports; carbon steel, $\frac{1}{4}$ in, design velocity, 3,600 fpm
 - Absorber outlet to baghouse inlet ductwork and supports; carbon steel, $\frac{1}{4}$ in, design velocity, 3,600 fpm
 - Baghouse outlet to new booster fans and fan outlet to the stack inlet ductwork and supports; carbon steel, $\frac{1}{4}$ in, design velocity, 3,600 fpm

4.2.2. FGD Island BOP

- a. Absorber tower foundations including caissons
- b. Baghouse area foundations including 18" auger cast piles 60' long
- c. Booster fan area foundations
- d. Concrete foundations for all flue gas ductwork

- e. 6” insulation with lagging for Absorbers, Baghouses and Ductwork
- f. Penthouse enclosure for Absorbers located in FGD Island
- g. Two elevators (one for each unit) to provide maintenance access to Absorber and Baghouse Areas
- h. Enclosure around hoppers for Baghouses located in FGD Island
- i. Lime preparation building for Reagent Preparation Area in FGD Island, including substructure and superstructure
- j. Byproduct recycle building for Byproduct Recycle Area in FGD Island, including substructure and superstructure

4.2.3. Reagent Storage and Handling, common to both units:

- a. Lime rail car unloader:
 - Lime delivery via 25-car unit train
 - System consists of mobile receiving pan and associated vacuum pneumatic equipment to unload railcar through railcar bottom hoppers
 - Enclosed railcar unloading building
 - One vacuum pneumatic system operating to unload a car
 - Pneumatic vacuum exhausters (2 x 100%)
 - Filter separator with vacuum-to-pressure transfer hopper and valves
 - Cost estimate based on vendor quote for a similar unit
- b. Lime storage silos:
 - Two lime storage silos, (14-day capacity each, common to both units) with bin vent filter, including substructure and superstructure
 - 1,000-tons storage, each
 - Continuous level detection systems
 - Live bottom hopper outlets
 - Rotary airlock assemblies
 - Lime transfer systems:
 - Pressure pneumatic conveying system from lime storage silos to lime day bins
 - Pneumatic pressure blowers
 - One lot of pneumatic conveying piping located on an elevated pipe rack
- c. Concrete foundations including caissons for all material silos
- d. Concrete foundations for pneumatic conveying blowers and exhausters

4.2.4. Byproduct Handling System, common to both units

- a. Two FGD by-product storage silos (7-day capacity each, common to both units) with bin vent filter, fluidizing system, and two unloading conditioners (one operating, one spare per silo), including substructure and superstructure
- b. One common fly ash blending, 7-day storage bin with bin vent filter, fluidizing system, and four pneumatic airslide conveyors
- c. Water pumps and associated piping for unloading conditioners (pin mixers) at both silos
- d. Continuous level detection system
- e. Two truck scales and substructure
- f. Concrete foundations including caissons for all material silos
- g. Concrete foundations for pneumatic conveying blowers and exhausters
- h. Allowance for existing road improvements for truck haulage to existing landfill

4.2.5. Civil BOP

- a. Site grading
- b. Soil removal earthwork
- c. Excavation, backfill, and compaction for all foundations
- d. Development of a new laydown area, approximately 10 acres, including site preparation, fencing, and temporary power. It was assumed that this area would be located on existing plant property, and does not require land to be purchased.

4.2.6. Mechanical BOP System

- a. Interconnecting piping, above-ground and buried
- b. Valves for interconnecting piping, above-ground and buried
- c. Lime slaking water storage tank, 175,000-gallon capacity
- d. Recycle make-up water tanks, 2 x 200,000-gallon capacity
- e. Pipe Racks, common to both units
 - Between lime railcar unloading enclosure and lime silos
 - Between lime silos and lime day bins
 - From baghouse hoppers to recycle silos and FGD by-product silo
 - From lime slurry storage tanks to absorber
 - From recycle slurry storage tank to absorber
 - Concrete foundations including caissons for all pipe racks
 - Shallow concrete foundations for other miscellaneous structures

- f. BOP Pumps
- Three by-product recycle water forwarding pumps to recycle slurry
 - Four reagent prep/recycle sump pumps
 - Two lime silo and unloading area sump pumps
 - Two by-product ash silo area sump pumps
 - Two by-product recycle make-up water tank supply pumps
 - Two lime slaking water pumps
- g. Instrument Air System, common to both units
- Air compressors; 2 x 100%,
 - IA dryers w/filters; 2 x 100%,
 - Air receivers; 2 x 100%
 - Instrument air piping to every silo or day bin, bin vent and reagent preparation/recycle area
 - Heat-traced piping
- h. Service Air System, common to both units
- Air compressors; 2 x 100%
 - Air receivers; 2 x 100%
- i. Field painting
- Multiple coat system used for exposed ductwork only
 - Inorganic zinc primer and polyurethane system used for steel
 - Allowance for underground piping shop coatings built into piping cost

4.2.7. Demolition and Relocation

- a. Allowance of \$1,800,000, plus labor costs, is included for demolition and relocation of existing equipment and infrastructure which may interfere with the new Dry FGD system. This allowance is based on recent in-house cost estimates for similar projects.

4.2.8. Electrical BOP System

- a. Allowances of \$13,900,000, \$8,500,000 and \$1,400,000, plus labor costs, are included for electrical equipment upgrades and modifications, cables and conduits/raceway, respectively. These allowances are based on recent in-house cost estimates for similar projects.

4.2.9. Instrumentation and Controls BOP System

- a. Allowance of \$1,585,000, plus labor costs, is include for DCS upgrades and added instrumentation. This allowance is based on recent in-house cost estimates for similar projects.

4.2.10. Labor Costs

Installation/labor costs were included in the base estimate under the direct costs. Manhours are estimated for each item in the base estimate and are based on the type of work and typical estimates for similar work. The labor costs are based on the labor wage rates and labor crews developed by S&L.

a. Labor Wage Rates

Crew labor rates were developed using prevailing craft rates, fringe benefits and state specific worker's compensation rates as published in the 2017 edition of R.S. Means Labor Rates for Pine Bluff, Arkansas area. Costs were added to cover FICA, workers compensation, all applicable taxes, small tools, incidentals, construction equipment, and contractor's overhead. A 1.15 geographic labor productivity multiplier is included based on the Compass International Construction Yearbook for Arkansas. The crew rates do not include an allowance for weather related delays.

b. Labor crews

Construction/erection labor cost is based on the use of applicable construction crews typically required for projects of this type. The construction crew costs were specifically developed for utility industry and are proprietary to S&L. The prevailing craft rates are incorporated into work crews appropriate for the activities, and include costs for small tools, construction equipment, insurance, and site overheads.

4.2.11. Other Direct and Construction Indirect Costs

In addition to the base labor costs, other construction indirect costs for the project were broken out in the estimate as well as other contractor direct costs. The following items were included as other direct and construction indirect costs.

- a. Scaffolding and Consumables
- b. Premiums and per diems (\$10 per hour)
- c. Overtime is included based on five 10-hour shifts per week work schedule
- d. Freight on construction materials
- e. Contractor's General & Administration Fees (included at 10% of total direct and construction indirect costs)
- f. Contractor's Profit (included at 5% of total direct and construction indirect costs)

4.2.12. EPC Indirect Costs

The final contribution to the overall EPC project price are the EPC Contractor's indirect costs; these include the EPC engineering services, startup spare parts and initial fills, technical field advisors, and the EPC risk fee.

a. EPC Engineering Services

The EPC engineering services was estimated based on recent projects with similar scopes and schedules. The total cost of the EPC engineering services was estimated to be \$23,000,000.

b. Startup Spare Parts and Initial Fills

An allowance has been included for initial fills for equipment, including first fills for lubrication of any motorized equipment. The initial fill of pebble lime was not included in the EPC Contractor's scope, as this is considered to be an operating cost rather than a capital expense. The initial fill of pebble lime is included in the Owner's costs. The total cost of the initial fills was estimated to be \$300,000.

c. Technical Field Advisors (Vendors)

Allowances were included for equipment supplier's technical field advisory services based on an estimated 600 man-days. The estimate includes technical field advisors for the FGD system supplier (including FGD system subcontractors) and the DCS supplier. The total cost of the technical field advisors was estimated to be \$600,000.

d. EPC Risk Fee

An EPC approach provides an alternative which is expected to reduce risk for Entergy by placing the responsibility for the project on a single entity, the EPC Contractor. The EPC risk fee is a premium charged by the contractor which accounts for the additional coordination and management of the project as well as the additional risk assumed by the contractor. Based on S&L's experience with recent EPC projects, an EPC risk fee was included at 10% of the total EPC project costs.

4.2.13. Owner's Costs and Services

Outside of the EPC Contractor's total cost, Entergy will incur other costs associated with the project, such as services procured from third parties (including Owner's engineer, construction management support, startup and commissioning support and performance testing), and other project related costs.

a. Owner's Costs

Owner's Costs are direct costs that the Owner incurs over the life of the project. The following items are real costs Entergy will incur to install DSI at Independence based on the scope and schedule of this project:

- Internal Labor
- Internal Indirects

- Travel Expenses
- Legal Services
- Builders Risk Insurance
- Initial Fills (Reagent)

Owner's costs were included in the estimate at 8% of the total project cost.

b. Construction Management Support

The construction management support was estimated based on similar project scopes. It was assumed that Entergy will not have the internal support personnel required to perform the tasks, and therefore it will be outsourced. The cost of labor is based on present day cost. The total cost of the construction management support was estimated to be \$4,969,000.

c. Startup and Commissioning Support

The startup and commissioning support was estimated based on similar project scopes. It was assumed that Entergy will not have the internal support personnel required to perform the tasks, and therefore it will be outsourced. The total cost of the startup and commissioning support was estimated to be \$550,000.

d. Owner's Engineer

The Owner's Engineer cost was developed as a high level estimate based on a typical scope for Owner's Engineer work for this type of project; including the following tasks:

- Conceptual Study Support
- EPC Specification Supporting Documents
- Project Schedule Development
- EPC Specification Development
- EPC Bid Evaluation and Contract Conformance
- General Project Support
 - Monthly Project Status Meetings
 - Weekly Teleconferences
 - Overall Coordination
 - Project Administration
 - Site Visits and Travel
- Permitting Support
- Design Review of Drawing Submittals
- Technical support during design, fabrication, construction, commissioning, and testing

- Equipment vendor QA/QC audits

The total cost of the Owner's Engineer was estimated to be \$6,500,000.

e. Performance testing

The cost for performance testing was developed as a factored estimate using costs from projects of similar scope. This cost includes the testing, performed by a third-party contractor hired by the Owner, and also includes the cost for S&L's assistance in the following tasks:

- Development of the test protocol
- Procuring the services of the testing contractor
- Overseeing the performance test campaign
- Evaluating the results of the testing with respect to guarantee compliance

The estimate for the third party testing contractor is based on the assumption that the contractor would be onsite for up to 5 days. The total cost of the Performance Testing was estimated to be \$275,000.

f. Contingency

Contingency is included in the estimate to cover the uncertainty associated with the project costs. The cost estimate includes a recommended contingency of 15% (due to a greater extent of project definition), which is consistent with cost estimating guidelines for a conceptual design and the current level of project definition. Contingency was applied to the total project costs before escalation.

g. Escalation

Escalation was included in the estimate based on a typical schedule for implementation of a Dry FGD system at an escalation rate of 2.15% on equipment and materials and 3.35% on labor and indirects. These escalation rates were developed by S&L based on recent pricing and in-house escalation projections.

h. Interest During Construction

Interest during construction (IDC) accounts for the time value of money associated with the distribution of construction cash flows over the construction period. IDC was applied to the total EPC project costs including contingency. The IDC was calculated based on a typical schedule for implementation of a DSI system and a typical interest rate of 7.8% per year which was assumed based on a low interest market environment.

4.3. VARIABLE OPERATING AND MAINTENANCE COSTS

The following unit costs were used to develop the variable Operating and Maintenance (O&M) costs. All of these values, with the exception of the reagent costs, were provided by Entergy or are typical industry values confirmed by Entergy. The reagent costs are based on recent supplier quotes for the area.

Table 4-1: Unit Pricing for Utilities (Provided by Entergy)

Unit Cost	Units	Value
Pebble Lime	\$/ton	\$130.0
High Quality Water	\$/1000 gal	\$2.00
Low Quality Water	\$/1000 gal	\$0.50
Byproduct Disposal	\$/ton	\$7.50
Aux Power Cost ¹	\$/MWh	\$43.35

Note 1: Entergy provided auxiliary power costs for the first year of operation.

Table 4-2 below summarizes the consumption rates estimated as well as the first year variable O&M costs for the Dry FGD system.

Table 4-2: Variable O&M Rates and First Year Costs, per Unit

	Units	Value
Dry FGD System Parameters		
Reagent Consumption	lb/hr	4,800
Byproduct Waste Production	lb/hr	10,600
Aux Power Consumption	kW	10,000
High Quality Water Consumption	gpm	50
Low Quality Water Consumption	gpm	880
First Year¹ Variable O&M Costs (@CF²)		
Reagent Cost	\$/year	\$2,050,000
Byproduct Waste Disposal Cost	\$/year	\$261,000
Aux Power Cost	\$/year	\$2,628,000
Water Cost	\$/year	\$213,000
Bag and Cage Replacement Cost	\$/year	\$372,000
Total First Year Variable O&M Cost	\$/year	\$5,524,000

Note 1: First year costs are provided in \$2017.

Note 2: The first year costs are calculated using an annual capacity factor of 75.0%.

4.4. FIXED OPERATING AND MAINTENANCE COSTS

The fixed O&M costs for the systems consist of operating personnel as well as maintenance costs (including material and labor). Based on the conceptual design for the dry FGD system, the estimated staffing additions are 28 personnel for two systems on adjacent units.

The annual maintenance costs are estimated as a percentage of the total capital equipment cost, based on the amount of operating equipment which will require routine maintenance. For this evaluation, the maintenance costs (maintenance and labor) were estimated to be approximately 1.3% of the project capital. This is a lower value than typical because items such as track work and civil work are high capital cost items with little to no maintenance.

Table 4-3 below summarizes the first year fixed O&M costs for the design and typical cases.

Table 4-1: First Year Fixed O&M Costs for Dry FGD, per Unit

First Year¹ Fixed O&M Costs	Units	Value
Operating Labor ²	\$/year	\$1,660,000
Maintenance Material	\$/year	\$975,000
Maintenance Labor	\$/year	\$650,000
Total First Year Fixed O&M Cost	\$/year	\$3,285,000

Note 1: First year costs are provided in \$2017.

Note 2: Operating labor costs are based on a labor rate of \$56.95, which was provided by Entergy.

Note 3: Installation of systems on both units would require 28 operators total. For accounting purposes, this is considered 14 operators per unit.

5. SUMMARY

The cost estimate for the Independence Units 1&2 Dry FGD systems is based on the addition of two SDA FGD systems for SO₂ removal. The attached capital estimate for the Independence Dry FGD system is based on this technical basis and is presented in 2017 dollars.

ADEQ Hearing: Regional Haze SIP Revision

January 19th, 2018

GOOD AFTERNOON. MY NAME IS GLEN HOOKS, AND I AM THE DIRECTOR OF THE ARKANSAS SIERRA CLUB. THANK YOU FOR THE OPPORTUNITY TO WEIGH IN ON THE DRAFT REGIONAL HAZE SIP REVISION. SIERRA CLUB WILL BE SUBMITTING DETAILED TECHNICAL COMMENTS PRIOR TO THE FEBRUARY 2ND DEADLINE, BUT I'LL OFFER SOME PRELIMINARY COMMENTS TODAY.

WE BELIEVE THAT THE DRAFT SIP IS ENTIRELY TOO WEAK. IT REQUIRES ALMOST NO ACTIONS ON THE PART OF ENTERGY TO CLEAN UP THE AGING, DIRTY, AND UNSCRUBBED WHITE BLUFF AND INDEPENDENCE COAL PLANTS. IT ALSO CONTEMPLATES A NOX TRADING PROGRAM THAT WILL PUT ARKANSAS COMMUNITIES AT RISK, AND FRANKLY CONTINUES AN UNBELIEVABLE DELAY IN ARKANSAS HAZE REDUCTION THAT IS ALREADY MORE THAN A DECADE OVERDUE.

Glen Hooks, Director
Arkansas Sierra Club
1308 West 2nd Street
Little Rock, AR 72201
Glen.Hooks@sierraclub.org

SINCE 1999, THE CLEAN AIR ACT HAS REQUIRED NUMEROUS STATES TO TAKE ACTION TO REDUCE SMOG/HAZE IN CERTAIN NATIONAL PARKS AND WILDERNESS AREAS, WITH THE GOAL OF RESTORING NATURAL VISIBILITY. HAZE IS LARGELY CAUSED BY POWER-PLANT AND INDUSTRIAL POLLUTION, AND COAL-BURNING POWER PLANTS ARE, BY FAR, THE LARGEST ^{SINGLE} EMITTERS OF HAZE-CAUSING POLLUTANTS IN ARKANSAS. AFFECTED STATES ARE REQUIRED TO DRAFT THEIR PLANS FOR HAZE REDUCTION AND GET THOSE PLANS APPROVED BY THE US ENVIRONMENTAL PROTECTION AGENCY. ARKANSAS IS ONE OF THOSE STATES.

TO BEGIN WITH, I'D LIKE TO ADDRESS OUR STATE'S INCREDIBLY IRRESPONSIBLE DELAY IN HAZE REDUCTION. THE ORIGINAL DEADLINE FOR ARKANSAS TO SUBMIT ITS STATE HAZE PLAN WAS IN 2007. ADEQ DRAFTED AND ~~FINALLY~~ SUBMITTED A HAZE REDUCTION PLAN IN ²⁰⁰⁸ 2011, WHICH EPA LARGELY REJECTED IN ²⁰¹² 2012 BECAUSE THE STATE FAILED TO ADDRESS THE BASIC

Glen Hooks, Director
Arkansas Sierra Club
1308 West 2nd Street
Little Rock, AR 72201
Glen.Hooks@sierraclub.org

REQUIREMENTS OF THE CLEAN AIR ACT—THE OBLIGATION TO ENSURE THAT THE OLDEST AND DIRTIEST SOURCES OF HAZE POLLUTION INSTALL “BEST AVAILABLE RETROFIT TECHNOLOGY” TO PROTECT AIR QUALITY IN NATIONAL PARKS AND WILDERNESS AREAS. INSTEAD OF SUBMITTING A REVISED PLAN FOR APPROVAL, ADEQ AFFIRMATIVELY CHOSE TO DO NOTHING AND NOT RESUBMIT.

THE STATE REFUSED TO RE-SUBMIT THE REJECTED PORTION, WHICH MEANT THAT THE EPA WAS REQUIRED BY FEDERAL LAW TO WRITE A PLAN FOR ARKANSAS. THE EPA TOOK ACTION, WROTE A PLAN, HELD A HEARING IN ARKANSAS, AND EVENTUALLY FINALIZED THE PLAN IN 2016, NEARLY A DECADE AFTER ARKANSAS WAS SUPPOSED TO SUBMIT THE ORIGINAL PLAN. THE EPA PLAN REQUIRED ENTERGY'S TWO OLDEST AND DIRTIEST COAL-BURNING POWER PLANTS (WHITE BLUFF AND INDEPENDENCE) TO INSTALL POLLUTION CONTROL EQUIPMENT ("SCRUBBERS"), AS A METHOD OF REDUCING THE HAZE PROBLEM IN OUR PARKS AND WILDERNESS AREAS. WHITE BLUFF AND INDEPENDENCE ARE AMONG THE LARGEST COAL-BURNING UNITS ANYWHERE IN THE COUNTRY THAT

Glen Hooks, Director
Arkansas Sierra Club
1308 West 2nd Street
Little Rock, AR 72201
Glen.Hooks@sierraclub.org

FOR ENTERGY TO REDUCE HAZE? BURN LOW-SULFUR COAL, WHICH
ENTERGY IS ALREADY DOING.

RESPECTFULLY, THIS IS NOT ENVIRONMENTAL ^{QUALITY} PROTECTION.

THIS IS A TIMELINE OF DELAY, REJECTED PLAN, A FAILURE TO TRY
AGAIN, THEN FIGHTING A WORTHY HAZE REDUCTION PLAN WHILE
SUBMITTING AN INFERIOR STATE PLAN YEARS AFTER THE FACT
THAT FAILS TO REDUCE HAZE BUT ADDS EVEN MORE DELAY.

IN ADDITION TO THE FAILURE TO REQUIRE SCRUBBERS ON
WHITE BLUFF AND INDEPENDENCE, THE DRAFT STATE PLAN GETS
RID OF SOURCE-SPECIFIC LIMITS ON NOX AND CONTEMPLATES
PARTICIPATION IN A TRADING PROGRAM INSTEAD. THE PROBLEM
HERE IS THAT SUCH A PLAN WILL ALLOW ENTERGY TO BUY
POLLUTION REDUCTION CREDITS IN FAR-AWAY STATES WHILE
CONTINUING TO POLLUTE ARKANSAS. WE URGE YOU TO SCRAP THIS
TRADING PROGRAM AND RETAIN THE SOURCE-SPECIFIC NOX LIMITS
THAT ARE CURRENTLY IN PLACE.

TO CONCLUDE: THE STATE HAZE REDUCTION PLAN BEING
CONSIDERED TODAY IS NOT SUFFICIENT. WE ARE MORE THAN A

Glen Hooks, Director
Arkansas Sierra Club
1308 West 2nd Street
Little Rock, AR 72201
Glen.Hooks@sierraclub.org

DECADE BEHIND IN HAZE REDUCTION EFFORTS—AND THAT IS
ALMOST ENTIRELY DUE TO THIS DEPARTMENT OF ENVIRONMENTAL
QUALITY DRAGGING ITS FEET AND THEN TRYING TO BLOCK
PROGRESS WHEN EPA STEPS IN AND MAKES PROGRESS HAPPEN.

IF YOU GENUINELY WANT HAZE REDUCTION, THEN REQUIRE
OUR STATE'S OLDEST, LARGEST, AND DIRTIEST UNSCRUBBED COAL
PLANTS TO INSTALL SCRUBBERS, JUST LIKE YOU DID IN THE ~~2011~~
HAZE REDUCTION PLAN THAT THIS DEPARTMENT SUBMITTED TO
EPA, ^{YEARS AGO}

INSTEAD

BUT IF YOU WANT DELAY AND YOU WANT NO PROGRESS ON
HAZE, AND YOU WANT OUR PARKS AND WILDERNESS AREAS TO
EXPERIENCE VISIBILITY PROBLEMS FOR EVEN LONGER THAN THEY
ALREADY HAVE—THEN CONTINUE BLOCKING A GOOD PLAN,
CONTINUE DELAY, AND APPROVE THIS WEAK, TOOTHLESS PLAN.

THANK YOU.

Re: Revisions to the Arkansas State Implementation Plan:
Regional Haze SIP Revisions for 2008-2018 Planning Period

Dear Ms. Treece:

Earthjustice, National Parks Conservation Association (“NPCA”), and Sierra Club (collectively, the “Conservation Groups”) hereby submit comments on “Revisions to the Arkansas State Implementation Plan: Regional Haze SIP Revisions for 2008-2018 Planning Period” (“Draft SIP”), a public review draft proposal issued by the Arkansas Department of Environmental Quality (“ADEQ”) in October 2017. Among other things, the proposal evaluates requirements for best available retrofit technology (“BART”) at the White Bluff coal-burning plant, and requirements for reasonable progress at the Independence coal-burning plant. For the reasons set forth in this letter, and under applicable standards, the proposal is unlawful and arbitrary, and must be withdrawn or significantly changed prior to issuance in final form.

I. REGIONAL HAZE

Air pollution destroys scenic vistas in our treasured national parks and wilderness areas. When Congress amended the Clean Air Act in 1977, it declared “as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution.” 42 U.S.C. § 7491(a)(1). “Mandatory class I” areas include 156 of the nation’s major parks and wilderness areas, including the Caney Creek Wilderness Area and the Upper Buffalo Wilderness Area. *Id.* § 7472; 40 C.F.R. § 81.404. The impairment of visibility, or haze, “reduces the clarity, color, and visible distance that one can see . . . [and] occurs virtually all the time at most national park and wilderness areas.” 76 Fed. Reg. 64,186, 64,188 (Oct. 17, 2011). The fine particulate

matter and other pollutants that impair visibility also can cause serious health effects and mortality in humans. *See* 64 Fed. Reg. 35,714, 35,715 (July 1, 1999).

Under the Act, each state in which a Class I area is located or which is the source of emissions that “may reasonably be anticipated to cause or contribute to any impairment of visibility” in a Class I area must submit an implementation plan that contains emission limits and compliance schedules “necessary to make reasonable progress toward meeting the national goal” of preventing and remedying visibility problems in the affected areas. 42 U.S.C. § 7491(b)(2). The U.S. Environmental Protection Agency (“EPA”) must approve or disapprove these plans based on whether they meet applicable requirements of the Clean Air Act. *Id.* § 7410(k), (l). If EPA finds that a state has failed to timely submit a required implementation plan or disapproves a submitted plan, EPA must promulgate a federal implementation plan (“FIP”) within two years of the finding of disapproval unless the state submits and EPA approves a plan before this deadline. *Id.* § 7410(c)(1).

A. Best Available Retrofit Technology

BART controls are required at fossil fuel-fired power plants and other major stationary sources that “may reasonably be anticipated to cause or contribute to any impairment of visibility in any such [mandatory Class I Federal] area,” and were in existence in 1977, but were not in operation before 1962. 42 U.S.C. § 7491(b)(2)(A); *see* 40 C.F.R. § 51.308(e).¹ BART is defined as “an emission limitation based on the degree of reduction achievable through the application of the *best* system of continuous emission reduction for each pollutant which is emitted by an existing stationary facility.” 40 C.F.R. § 51.301 (emphasis added).

When determining BART, the states and EPA must analyze “the best system of continuous emission control technology available” by taking into consideration five factors: (1) the costs of compliance, (2) the energy and non-air quality environmental impacts of compliance, (3) existing pollution controls at the source, (4) the remaining useful life of the source, and (5) the degree of visibility improvement from pollution controls. *Id.* § 51.308(e)(1)(ii)(A). BART is an essential component of the regional haze program because Congress largely grandfathered these antiquated sources into many of the Clean Air Act’s other requirements. *See* 70 Fed. Reg. 39,104, 39,111 (July 6, 2005). BART compels these older, disproportionately polluting sources to install up-to-date and cost-effective pollution controls. BART is a mandatory measure that must be implemented as part of a plan to achieve reasonable progress toward restoration of natural visibility conditions. 42 U.S.C. § 7491(b)(2). BART is subject to limited exceptions (*see id.* § 7491(c)) that are not applicable here, given the significant impact Arkansas sources have on Class I areas.

B. Reasonable Progress Goals and Controls

One of the main features of the Regional Haze Rule is the establishment of goals, expressed in deciviews to measure visibility impairment, that “provide for reasonable progress

¹ The term “major stationary source” includes any source that has the potential to emit 250 tons per year or more of any pollutant, and falls within one of 26 categories of industrial sources defined by the Act. 42 U.S.C. § 7491(g)(7).

towards achieving natural visibility conditions.” 40 C.F.R. § 51.308(d)(1). In developing these “reasonable progress goals” (“RPGs”) and the emission reductions needed to meet them, the state must consider four factors: (1) the costs of compliance, (2) the time necessary for compliance, (3) the energy and non-air quality environmental impacts of compliance, and (4) the remaining useful life of any potentially affected sources. 42 U.S.C. § 7491(g)(1); 40 C.F.R. § 51.308(d)(1)(i)(A).²

For each Class I area within its borders, a state must determine the uniform rate of progress (“URP”), which is the amount of progress that, if kept constant each year, would ensure that natural visibility conditions are achieved in 2064. *See* 40 C.F.R. § 51.308(d)(1)(i)(B). If a state selects a reasonable progress goal that achieves a slower rate of progress than the URP, the state must demonstrate, based on the four reasonable progress factors, “that the rate of progress for the implementation plan to attain natural conditions by 2064 is not reasonable; and that the progress goal adopted by the State is reasonable.” *Id.* § 51.308(d)(1)(ii).

C. Long-Term Strategy

A regional haze implementation plan must include, among other things, emission limits, schedules of compliance, and any other measures necessary to achieve the reasonable progress goals; these enforceable measures are called the long-term strategy. 40 C.F.R. § 51.308(d)(3)(ii). To eliminate haze caused by manmade air pollution, states must consider all air pollution sources that contribute to impairment in Class I areas. In developing a long-term strategy, a state must look at and beyond major stationary sources, including area, mobile, and minor sources as well as a number of other sources of impairment such as construction, agricultural, and forestry practices. *Id.* § 51.308(d)(3)(iv, v). The long-term strategy must achieve reasonable progress for both the Class I areas within a state’s borders as well as the out-of-state areas affected by the state’s emissions. *Id.* § 51.308(d)(3). To ensure that each state does its part to address regional haze, a state that contributes to impairment at another state’s Class I area must consult with the state that is home to the Class I area. *Id.* § 51.308(d)(3)(i).

II. REGIONAL HAZE IN ARKANSAS

A. Class I Areas Polluted by Emissions from Arkansas Sources

Emissions from Arkansas sources impact two in-state Class I areas: Caney Creek Wilderness Area and Upper Buffalo Wilderness Area. Caney Creek straddles two different sections of the Ouachita Mountains in western Arkansas. The Fourche Mountain subsection is characterized by deep slices carved by streams out of the ridges, large rock flows, and sandstone bluffs.³ The Upper Buffalo Wilderness Area in the Ozark Mountains provides visitors the opportunity to “be among the headwaters of the extraordinarily pretty

² In contrast to the definition of BART, the statute does not list visibility improvement as a fifth factor in the reasonable progress analysis. *Compare* 42 U.S.C. § 7491(g)(1) *with id.* § 7491(g)(2).

³ “Wilderness Stewardship Challenge: Air Quality Values Monitoring Plan for Ouachita National Forest, Arkansas and Oklahoma,” p. 17 (Sep. 30, 2009) available at: http://www.fs.usda.gov/Internet/FSE_DOCUMENTS/stelprd3811710.pdf.

Buffalo National River, which flows down the center of this Wilderness through a rough forested land of steep slopes that descend into deep valleys.”⁴ The Whitaker Point Trail winds its way to the top of Hawksbill Crag,⁵ a scenic rocky outcropping which is one of the most photographed places in Arkansas.⁶

Air pollution from Arkansas sources mars the unique scenery outside of the state too, including in Missouri’s Hercules Glades Wilderness Area and Mingo National Wildlife Refuge. The Hercules Glades Wilderness spans 12,413 acres of some of the “most scenic and unique country in the Midwest” with “[i]ts combination of open grassland, forested knobs, steep rocky hillsides, and narrow drainages offers unusual beauty.”⁷ The 21,592-acre Mingo National Wildlife Refuge provides food and shelter for migratory waterfowl and protects a bottomland hardwood forest.⁸

B. Arkansas Haze Pollution Sources

Electric generating units (“EGUs”) emit the overwhelming majority of haze-causing pollutants in Arkansas. Of these pollutants, sulfates and nitrates contribute most significantly to the visibility problem in Arkansas’s Class I areas.⁹

The Independence plant is an 1,800 MW coal-burning electric generating station operated by Entergy Arkansas, Inc. The plant consists of two nearly identical 900 MW units which burn subbituminous coal. The Independence units began operation in 1983 and 1984, respectively, are not BART-eligible, and have no SO₂ controls. In 2017, Entergy installed low-NO_x burners and separated over-fire air (“LNB/SOFA”) at Independence Units 1 and 2.¹⁰ The units are equipped with electrostatic precipitators to control particulate matter emissions. According to emissions data from EPA’s Clean Air Markets Database, Independence was the largest point source of both sulfur dioxide and nitrogen oxide emissions in the state in 2016.¹¹ The Independence plant contributes significantly to visibility impairment at all four Class I areas modeled by EPA, with the largest SO₂ impacts at Caney Creek Wilderness Area (98th percentile impairment of 2.412 deciviews), Upper Buffalo Wilderness Area (98th percentile

impairment of 1.764 deciviews), and Hercules-Glades Wilderness Area (98th percentile impairment of 1.704 deciviews). 80 Fed. Reg. 18,944, 18,994, Table 64.

The White Bluff plant is a 1,700 MW coal-burning electric generating facility operated by Entergy. The plant consists of two nearly identical 850 MW tangentially fired boilers that burn subbituminous coal. 80 Fed. Reg. at 18,969. White Bluff Units 1 and 2 currently have no SO₂ controls, but Entergy has installed low-NO_x burners and separated over-fire air (“LNB/SOFA”) at White Bluff Unit 2 and intended to install LNB/SOFA at White Bluff Unit 1 in mid-January to comply with EPA’s regional haze FIP and other requirements.¹² The plant is equipped with electrostatic precipitators to control particulate matter emissions. According to 2016 emissions data in EPA’s Clean Air Markets Database, the White Bluff plant was the second largest point source of emissions of both sulfur dioxide and nitrogen oxide in the state. White Bluff Units 1 and 2 contribute significantly to visibility impairment at all four Class I areas modeled by EPA, with the largest impacts at Caney Creek Wilderness Area (98th percentile impairment of 3.323 dvs), Upper Buffalo Wilderness Area (98th percentile impairment of 2.325 dvs), and Hercules-Glades Wilderness Area (98th percentile impairment of 2.101 dvs). *See id.* at 18,970, Table 31.

C. Development of the Regional Haze Plan for Arkansas

The current ADEQ SIP proposal is the latest in a series of actions regarding regional haze in Arkansas. ADEQ submitted a proposed regional haze SIP to EPA in 2008 and 2010, and supplemented its proposal in 2011. 77 Fed. Reg. 14,603, 14,604 (Mar. 12, 2012). In 2012, EPA issued a final rule approving in part and disapproving in part Arkansas’s regional haze and interstate transport SIP. *Id.* at 14,604. Among other things, EPA disapproved ADEQ’s BART determination for Entergy White Bluff Units 1 and 2, and disapproved ADEQ’s reasonable progress goals for failure to consider all four required factors. *Id.* at 14,605.

EPA issued a final Arkansas haze federal implementation plan in 2016. EPA’s FIP established new BART requirements for White Bluff and other sources. 81 Fed. Reg. 66,332, 66,339 (Sept. 27, 2016). The FIP also established limits on nitrogen oxides and sulfur dioxide for Independence under reasonable progress requirements. *Id.* at 66,352-54. In April 2017, EPA announced its reconsideration of some elements of the FIP, and later issued a 90-day administrative stay of NO_x compliance dates in the FIP. 82 Fed. Reg. 18,994.

On May 26, 2017, in advance of haze state plan revisions, the Conservation Groups submitted technical information to ADEQ regarding best available retrofit technology limits at White Bluff and reasonable progress requirements for Independence.¹³

In July 2017, ADEQ submitted a SIP revision to replace nitrogen oxide limits under the FIP, including limits per BART and reasonable progress, with reliance on the federal Transport

¹² *See Ex. A (Entergy Am. and Substituted Mot. to Stay Final Rule, Decl. of Bryan Sikes ¶ 10, Arkansas v. U.S. E.P.A., Case No. 16-4270 (filed 8th Cir. Jan. 11, 2018) (ECF No. 4619424).*

¹³ Conservation Groups, Letter to ADEQ, Technical Information Regarding BART Limits for White Bluff and Reasonable Progress Limits for Independence, May 26, 2017.

Rule.¹⁴ On January 26, 2018, EPA signed the pre-publication version of a final rulemaking approving the NO_x SIP and withdrawing the NO_x FIP. Also, in advance of the current SIP proposal, Conservation Groups submitted information on reasonable progress for sulfur dioxide at Independence.¹⁵

III. WHITE BLUFF

The proposed state plan evaluates best available retrofit technology for White Bluff based on a five-factor analysis submitted by Entergy (at 21-25). The plan evaluates four technically feasible controls for sulfur dioxide (low sulfur coal, dry sorbent injection, dry scrubbers and wet scrubbers) in terms of the five BART factors, and ratifies Entergy's proposal that low sulfur coal with an emission rate of 0.6 lb/MMBtu on a 30-day rolling average is BART for White Bluff Units 1 and 2 (at 25). The proposal relies on an administrative order ("AO") that will include "enforceable limitations and compliance dates consistent with ADEQ's determination" (at 25). The proposal also notes EPA's approval in 2012 of BART limits for particulate matter (at 25).

The proposed SO₂ BART determination is arbitrary and unlawful for several reasons.

A. ADEQ Improperly Relies on an Administrative Order that Is Vague and Unenforceable.

In its proposed plan, ADEQ relies on provisions contained in administrative orders for several plants. Proposed SIP, Tab C. For White Bluff, ADEQ's issuance of a BART determination that impermissibly relies upon an unenforceable and vague administrative order violates both the requirement that BART include enforceable emission limits, 40 C.F.R. pt. 51, App. Y § V, as well as the requirement that BART be installed and operated as expeditiously as practicable, 42 U.S.C. § 7491(b)(2)(A).

First, ADEQ's reliance on the draft AO unlawfully fails to include enforceable emission limits because the administrative order for White Bluff as well as other plants are not final actions. A BART determination that relies on an unsigned, draft order cannot be approved by EPA.

Second, even if the AO were not in draft form, the terms of the administrative order for White Bluff would still be vague and unenforceable, in violation of the requirement that BART include enforceable emission limits, 40 C.F.R. pt. 51, App. Y § V ("To complete the BART process, you must establish enforceable emission limits that reflect the BART requirements and require compliance within a given period of time. In particular, you must establish an enforceable emission limit for each subject emission unit at the source and for each pollutant subject to review that is emitted from the source.").¹⁶ The White Bluff AO provides that the

¹⁴ ADEQ, Revisions to the Arkansas State Implementation Plan, Regional Haze SIP Revision for 2008-2018 Planning Period, July 2017.

¹⁵ Conservation Groups, Letter to ADEQ, Regional Haze Reasonable Progress Limits for Independence 1 and 2, Sept. 29, 2017.

¹⁶ ADEQ must determine BART for White Bluff pursuant to EPA's BART Guidelines because the entire White Bluff plant has a nameplate capacity greater than 750 MW. *See* 42 U.S.C. § 7491(b)(2).

units shall comply with sulfur dioxide limits “within three years of the effective date of this AO and with Entergy’s execution of its intended changes to operations at the White Bluff facility Units 1 and 2 indicated in their comments to EPA’s federal implementation plan of Aug. 7, 2015 cited in their Petition for Reconsideration dated Nov. 23, 2015¹⁷, no later than December 31, 2030.” Proposed SIP, Tab C, White Bluff Administrative Order, at pdf 1776 ¶ 3.

This draft order, even if it were fully executed and in final form, does not create an affirmative obligation to shut down White Bluff, or take any other action other than use low-sulfur coal, by December 31, 2030. Any limit that is contingent upon “Entergy’s execution of intended changes” as “indicated in their comments to EPA” is not an “enforceable emission limit” under the BART Guidelines. While the end of the quoted sentence purports to provide an outside deadline of December 31, 2030, the Entergy comments referenced in the AO state:

As part of a multi-unit plan to improve visibility and to better manage its generation assets for reliability and costs, Entergy proposes to cease burning coal at White Bluff Units 1 and 2 by 2027 and 2028, one unit per year, and is prepared to take an enforceable commitment to that effect. Such incorporation should not be construed to limit ADEQ’s discretion to reopen the requirements of this CAO for consistency with future state implementation plan revisions as stated in paragraph nine.

Entergy Arkansas Inc. Comments on the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 5 (Aug. 7, 2015) (Docket ID No. EPA-R06-OAR-2015-0189-0166). Under this provision, Entergy merely “*proposes* to cease burning coal” and “*is prepared* to take” a commitment. Moreover, Entergy includes a reopener for the entire White Bluff AO for “consistency,” which is not itself defined, with unspecified future state plans.

Entergy’s purported “intent” to cease coal burning comes with another problematic caveat. The Company maintains that its compliance with a final FIP, including installing dry scrubbers or, in the alternative, ceasing coal-burning operation at White Bluff, will be subject to Arkansas Public Service Commission hearing and review.¹⁸ Entergy appears to suggest that whether it ceases to burn coal at White Bluff is contingent on receiving approval from the Arkansas Public Service Commission. But a BART determination must be enforceable—it

¹⁷ Entergy Arkansas Inc. Petition for Reconsideration and Request for Stay of Entergy Arkansas Inc., at 6 (Nov. 23, 2015) (In re: Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan, EPA Docket No. EPA-R06-OAR-2015-0189) at p. 6 (“Entergy explicitly made such a commitment in its comments on the Proposed FIP: . . . ‘As part of a multi-unit plan to improve visibility and to better manage its generation assets for reliability and costs, Entergy proposes to cease burning coal at White Bluff Units 1 and 2 by 2027 and 2028, one unit per year, and is prepared to take an enforceable commitment to that effect.’”)(citing Entergy Arkansas Inc. Comments on the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 5 (Aug. 7, 2015) (Docket ID No. EPA-R06-OAR-2015-0189-0166)).

¹⁸ *Id.*

cannot be contingent on the approval of a state public service commission. The contingent nature of ADEQ's BART determination is unlawful.

Finally, for the same reasons, the Order's failure to require White Bluff to take a specific action by a specific date violates the statutory requirement to install and operate BART as expeditiously as practicable, but in no event later than five years after the date of approval of a plan. *See* 42 U.S.C. § 7491(b)(2)(A); *see also* 40 C.F.R. § 51.308(e)(1)(iv).

B. ADEQ Uses a Remaining Useful Life that is Unlawful.

In its proposal, ADEQ states that "Entergy's cost-effectiveness calculations are reasonable based on a remaining useful life of seven years and Entergy's proposal to take an enforceable limit regarding the timing of their planned changes in coal-fired operations date." Draft SIP at 24. Under ADEQ's analysis, the remaining useful life of seven years begins in 2023 and ends in 2030. The remaining useful life is flawed because both the beginning and ending dates do not comport with applicable requirements, as explained below.

1. The Remaining Useful Life of White Bluff Must Begin in 2021.

ADEQ acknowledges that "the remaining useful life calculation should begin on 'the date that controls will be put in place' (compliance date)," Draft SIP at 24, but misapplies the BART Guidelines to the facts here. The existing FIP requires White Bluff Units 1 and 2 to meet new SO₂ limits no later than October 27, 2021. 40 C.F.R. § 52.173(c)(7). The FIP's SO₂ limits for White Bluff remain in effect, as EPA has not reconsidered or stayed those provisions, and no court has stayed those provisions. As a result, the 2021 deadline in the existing FIP is the "date that [SO₂] controls will be put in place" at White Bluff and, under the BART Guidelines, October 27, 2021 must be the starting date for any remaining useful life analysis.

Even if it were permissible for ADEQ to ignore the FIP compliance deadline, which it is not, ADEQ provides no rational basis for assuming a 2023 compliance date for any SO₂ controls. Here, ADEQ proposes a SO₂ BART emission limit based on the use of low-sulfur coal. BART must be installed and operated as "expeditiously as practicable." 42 U.S.C. § 7491(b)(2)(A). White Bluff could switch to low-sulfur coal in less than five years, and thus it would violate 42 U.S.C. § 7491(b)(2)(A) to issue a BART determination based on the use of low-sulfur coal with a compliance deadline of 2023. Accordingly, ADEQ has no lawful basis for using 2023 as the beginning date for a remaining useful life analysis.

Even with respect to consideration of scrubbers as a BART control, it is arbitrary to use 2023 as the assumed compliance deadline. The existing FIP already requires White Bluff to meet SO₂ emission limits based on the use of new scrubbers. *See* 40 C.F.R. § 52.173(c)(6)-(7). If ADEQ were to require as BART an emission limit based on the use of scrubbers, it would be arbitrary to grant White Bluff a two-year compliance extension, because White Bluff is required to meet the limits in the FIP by the existing 2021 deadline.

2. *ADEQ Has No Rational Basis for Using 2030 as the End of The Remaining Useful Life of White Bluff.*

ADEQ notes the requirement in the BART Guidelines that if a shorter remaining useful life is used, based on a facility shutting down, “the permanent operations cessation date should be ‘assured by a federally- or State-enforceable restriction preventing further operation.’” Draft SIP at 24. ADEQ violates this requirement by assuming that White Bluff will shut down no later than 2030, yet failing to make this shutdown legally enforceable, as explained above, *supra* Section III.A. It is unlawful for ADEQ to assume, for purposes of the remaining useful life analysis, that White Bluff will shut down by a date certain unless ADEQ adds a new provision to the SIP that makes enforceable the requirement for White Bluff to cease burning coal or cease all operations by the date used in the remaining useful life analysis.

Furthermore, ADEQ provides no rationale for selecting 2030 as the end of White Bluff’s remaining useful life. Indeed, ADEQ’s assumption that White Bluff will cease to burn coal or retire by 2030 is inconsistent with the very comments that ADEQ cites in the administrative order for White Bluff. The AO reference’s Entergy’s comments, which state that Entergy proposes to cease burning coal by 2028—not 2030. Entergy Arkansas Inc. Comments on the Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 5 (Aug. 7, 2015) (Docket ID No. EPA-R06-OAR-2015-0189-0166). ADEQ appears to have simply invented a 2030 shutdown date that has no support in the administrative record, even if it were assured by an enforceable restriction, which it is not.

C. ADEQ Fails to Articulate Any Threshold for Determining When Controls are Cost-Effective.

In its review of technology options for White Bluff, ADEQ cites Entergy data regarding the cost-effectiveness of technology for reducing sulfur dioxide emissions, including dry sorbent injection (\$6,239 per ton of sulfur dioxide reduced), “enhanced” dry sorbent injection (\$6,405/ton), dry flue gas desulfurization, and low sulfur coal (\$1,150/ton). Draft SIP at 23. ADEQ then states: “The cost-effectiveness estimates for all control options evaluated, with the exception of LSC, are greater than what is *typically considered cost-effective*. *Id.* (emphasis added). Based on these cost-effectiveness estimates, ADEQ concludes that DSI, Dry FGD, and Wet FGD are not BART.”

However, ADEQ does not explain what is “typical” for cost-effectiveness, nor whose “consideration” of cost-effectiveness is the basis for its decision. Nor does ADEQ provide justification for why it should be regarding “typical” cost effectiveness as the standard for determining BART where BART is to be determined on a case-by-case basis taking into account the four other BART factors beyond cost. And ADEQ does not provide any supporting evidence for its assertion that the control costs for FGD and DSI “are greater than what is typically considered cost-effective.” Instead, ADEQ summarily, and improperly, dismisses three effective technologies for sulfur dioxide pollution control.

Moreover, contrary to ADEQ’s conclusory assertion, dry FGD for White Bluff would be well within the range of cost-effectiveness that states and EPA have found to be reasonable for BART, as shown in the table below. The table below reflects final BART FIP and SIP decisions

for NO_x and SO₂ for 71 different coal-burning EGUs across the country, as reported in the respective decision-making documents. *See* BART Cost Effectiveness Spreadsheet, Ex. B. These costs have not been updated or adjusted to a consistent cost year. But in some cases where cost effectiveness was reported on a source-wide basis, adjustments have been made to split those costs to a per-unit basis. As EPA concluded in its September 27, 2016 FIP, the installation of dry FGD at White Bluff units 1 and 2 would reduce SO₂ pollution by 14,363 and 15,221 tons per year, respectively; resulting in a cost-effectiveness of \$2,565/ton and \$2,421/ton, respectively. 80 Fed. Reg. at 18,971, 81 Fed. Reg. 66,386. This is well within the range of costs that EPA and other states have typically considered cost-effective.

D. The Proposed Compliance Deadline for Meeting Limits Based on the Use of Low-Sulfur Coal is Unsupported and Unlawful.

For the reasons explained above, ADEQ’s proposed BART determination for White Bluff is arbitrary and capricious and contrary to law. But even if ADEQ could lawfully approve low-sulfur coal as BART for White Bluff (which it cannot), ADEQ’s proposal to allow Entergy *another three years* to comply with that flawed BART emission limit, Draft SIP at 25, is flatly inconsistent with the record and the Clean Air Act. Under the plain terms of the Clean Air Act, ADEQ cannot allow Entergy three more years to comply with an emission limit that it is already capable of achieving.

The Clean Air Act and the Regional Haze Rule require any source subject to BART to install and operate the appropriate technology “*as expeditiously as practicable*” but in no event later than five years” after approval of a SIP or issuance of a FIP. 42 U.S.C. § 7491(b)(2)(A), (g)(4) (emphasis added). The time necessary for compliance generally should be considered on a

source-by-source basis, with “each source required to comply by the *soonest date* that can be considered reasonable.”¹⁹ Indeed, the common meaning of the phrase “as expeditiously as practicable” is as “promptly” as “feasible.”²⁰

In determining the appropriate compliance deadline for BART, EPA’s analogous “reasonably available control measure” (“RACM”) guidance for ensuring attainment of the National Ambient Air Quality Standards (“NAAQS”) is instructive. Like the BART provisions of the Act, sources in nonattainment areas (*i.e.*, those areas failing to meet the NAAQS) must implement all reasonably available control measures, including “reasonably available control technology” (“RACT”) emission limits “as expeditiously as practicable.” 42 U.S.C. § 7502(c)(1).²¹ In order for the EPA to determine whether a State has adopted all RACM necessary for attainment as expeditiously as practicable:

the State must explain why the selected implementation schedule is the earliest schedule *based on the specific circumstances* of that area. Such claims *cannot be general claims* that more time is needed but rather should be *specifically grounded in evidence of economic or technologic infeasibility . . .*²²

EPA must then review the state’s submission to “ensure that sufficient information is provided” for the EPA to determine whether the State has provided for implementation of all reasonably available control measures as expeditiously as practicable.²³ Just as EPA must ensure that the state provides *specific* information demonstrating that RACM is implemented as expeditiously as practicable, the agency must also closely examine the state’s submission to ensure that the state adequately explains any delay in implementing BART. *See North Dakota v. EPA*, 730 F.3d 750, 761 (8th Cir. 2013) (citing *Alaska Dep’t of Envtl. Conservation v. EPA*, 540 U.S. 461, 485, 490 (2004) (EPA must ensure that the state’s regional haze plan is “reasonably moored to the Act’s provisions” and based on “reasoned analysis” of the facts).

ADEQ proposes to require compliance with a low-sulfur coal emission limit “three years after approval of this SIP revision,” based solely upon Entergy’s assertion “[i]n communication with ADEQ” that “it is their practice to project how much coal will be needed in future years and to contract for a portion of their coal supply up to three years in advance.” Draft SIP at 25. However, there is no specific technical or economic evidence in the record to support Entergy’s conclusory assertion that more time is needed to implement EPA’s flawed low-sulfur coal BART

¹⁹ See EPA, Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at 114 (July 2016) (emphasis added) (discussing appropriate time for compliance for measure to ensure reasonable progress).

²⁰ Webster’s New Collegiate Dictionary at 403, 902 (1976).

²¹ RACT is defined as an “emission limit” that a particular source is capable of meeting by the application of control technology that is reasonably available considering technological and economic feasibility.

²² Ex. C, Memo. From John S. Seitz, Director, Office of Air Quality Planning and Standards, to Regional Air Division Directors, “Guidance to Clarify EPA’s Policy on What Constitutes ‘As Expeditiously as Practicable’ for Purposes of Attaining the One-Hour Ozone Standard for Serious and Severe Ozone Nonattainment Areas.” (Nov. 1999).

²³ *Id.*

determination. In fact, the “communication” that purportedly supports ADEQ’s compliance deadline is not even in the record.

In any event, the record flatly contradicts Entergy’s assertion that White Bluff needs three more years to transition to low-sulfur coal to meet a limit of 0.6 lbs/MMBtu. Indeed, the record indicates that Entergy is *already* capable of complying with—and indeed, already meeting—the 0.6 lbs/MMBtu limit. Draft SIP at 22 (“The average monthly emissions rate between 2014 and 2016 was 0.55 lb SO₂/MMBTU for Unit 1 and 0.58 lb SO₂/MMbtu for Unit 2.”). Thus, the only “specific” technical or economic evidence in the record makes clear that White Bluff is either already meeting that limit, or capable of doing so.

Moreover, nothing in the record demonstrates that it would be impracticable to meet a 30-day rolling average of 0.6 lbs/MMBtu right now. ADEQ states, without any support, that it is Entergy’s “practice to project how much coal will be needed in future years and to contract for a portion of their coal supply up to three years in advance.” Draft SIP at 25. But Entergy’s explanation fails to demonstrate that it is bound to any specific coal contract or practice, or that it is economically or technically impracticable to switch to low-sulfur coal now. At best, Entergy suggests that it would be inconvenient for the Company to do so. Under the Clean Air Act’s regional haze provisions, however, it is irrelevant whether compliance is inconvenient or a departure from preferred practice. Instead, BART must be installed “as expeditiously as practicable.” 42 U.S.C. § 7491(b)(2)(A). And the record indicates it would be practicable for White Bluff to meet a 30-day rolling average of 0.6 lbs/MMBtu right now.

Similarly, there is nothing in the record to suggest that additional equipment is needed at White Bluff to switch coal or blend its fuel stock. As ADEQ notes, “no capital investments in equipment are required” to switch to low-sulfur coal. Draft SIP at 25. Even if some additional equipment is required (and there is no evidence that it is), ADEQ has failed to provide a rational explanation for such a conclusion. In any event, Entergy clearly has the technical ability to blend its coal supply because, as the proposed SIP makes clear, the Company has been purchasing and using lower-sulfur coal for several years. *Id.* In sum, without basic information regarding Entergy’s existing equipment or the costs of obtaining any necessary new equipment, it is impossible for ADEQ to make a “reasoned” evaluation of the facts and rationally conclude that more time is necessary to meet ADEQ’s flawed BART limit. *See North Dakota v. EPA*, 730 F.3d at 761.²⁴

Finally, neither Entergy nor ADEQ considered alternatives to extending the compliance deadline by three years. There is no evidence in the record showing that ADEQ considered the costs for Entergy to purchase the low-sulfur coal and fuel blending equipment necessary to meet the compliance deadline before 2020. Nor is there any evidence that the State considered

²⁴ Even if Entergy had already contracted for a portion of its coal supply, the Company could accept penalties for cancellation. This would require no fuel blending equipment. But neither Entergy nor ADEQ seem to have explored such an option. At a minimum, ADEQ must verify that Entergy has contractual obligations for coal supplies, and should require information about the cost of penalties which would result from Entergy cancelling any portion of its supply that would preclude compliance with a 0.6 lb/mmBTU limit.

alternatives such as lengthening the averaging time, or complying with an annual limit for 2018 and 2019, followed by a 30-day rolling average for 2020.

E. A Proper BART Analysis Indicates that SO₂ BART for White Bluff is an Emission Limit Based on the Use of a Scrubber.

As explained above, and in the accompanying report of Vicki Stamper, currently there is no enforceable requirement for White Bluff Units 1 and 2 to cease burning coal or cease all operations by a date certain.²⁵ As a result, a 30-year remaining useful life is appropriate for assessing control options in the White Bluff BART analysis. Using a 30-year remaining useful life, the installation of dry FGD at White Bluff units 1 and 2 would reduce SO₂ pollution by 14,363 and 15,221 tons per year, respectively; resulting in a cost-effectiveness of \$2,565/ton and \$2,421/ton, respectively. 80 Fed. Reg. at 18,971, 81 Fed. Reg. 66,386. Those controls would result in a result in a greater than 5.6 dv visibility improvement across the four modeled Class I areas. 81 Fed. Reg. 66,343.

The remaining BART factors are neutral, as there are no non-air quality impacts of the controls that weigh against their selection, and there are no post-combustion SO₂ controls in use at White Bluff. The cost-effectiveness of dry FGD is well within the range of cost-effectiveness values of other BART determinations, *see supra* Section III.C; BART Cost Effectiveness Spreadsheet, Ex. A, and dry FGD would improve visibility significantly (and more than DSI or low-sulfur coal would).²⁶ For these reasons, SO₂ BART for White Bluff is an emission limit of 0.06 lb/MMBtu, based on the use of dry FGD.

Even if ADEQ were to finalize an enforceable instrument that unambiguously requires White Bluff to cease coal use by a date certain, BART must still be based on the use of dry FGD. As the accompanying Stamper Report indicates, dry FGD is still cost-effective even with a 5, 7, or 9-year remaining useful life.²⁷ Thus, under any BART analysis in which the remaining useful life is 5 years or greater, SO₂ BART for White Bluff is an emission limit of 0.06 lb/MMBtu, based on the use of dry FGD.

In the alternative, if ADEQ does not determine SO₂ BART to be dry FGD, SO₂ BART for White Bluff must, at a minimum, be based on the use of DSI. As explained in the Stamper Report, an emission limit based on the use of DSI—either at 50% or 80% reduction—is well within the range of costs that EPA and states have found reasonable if the remaining useful life is between 5 and 9 years.

²⁵ Ex. D at 4-6, Victoria R. Stamper, Technical Support Document to Comments of Conservation Organizations, Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period (Feb. 1, 2018) [hereinafter "Stamper Report"].

²⁶ According to Entergy's BART analysis, low sulfur coal would result in less than a deciview improvement across all four affected Class I areas. Entergy Arkansas, White Bluff Steam Electric Station, BART Five-Factor Analysis at 4-7 and 4-8 (Trinity Consultants (Aug. 18, 2017).

²⁷ *See* Stamper Report at 23 (Table 2), 25 (Table 3), 26 (Table 4).

IV. INDEPENDENCE

The Draft SIP describes how ADEQ considered reasonable progress controls for Independence (at 42-46). ADEQ describes Independence as similar in configuration to White Bluff, with similar control technology costs (at 42), although Independence is not subject to BART due to the date of boiler installation. ADEQ identified three technologically feasible control options at Independence: low sulfur coal, dry scrubbers, and wet scrubbers. ADEQ cited lower dispatch as an explanation for decreasing emissions from Independence (at 43). ADEQ reviewed the reasonable progress factors, and concludes that Independence should meet a limit based on low sulfur coal with no add-on controls (at 47).

As explained below, the proposed determination of SO₂ controls for Independence is arbitrary and capricious and contrary to law.

A. ADEQ's Assertion that the Cost-Effectiveness of Scrubbers Exceeds Screening Thresholds is Unsupported and Incorrect.

ADEQ rejects scrubbers as reasonable progress controls in part because “Both Entergy’s and EPA’s cost-effectiveness estimates for Dry FGD at Entergy Independence exceed screening thresholds used for cost-effectiveness in other approved reasonable progress analyses.” Draft SIP at 47. ADEQ provides only a single citation to support this assertion, the 2011 Kentucky regional haze rule, 76 Fed. Reg. 78,194. Draft SIP at 47 n.48.

But contrary to ADEQ’s assertion, scrubbers for Independence are more cost-effective than reasonable progress measures required in other haze plans. Indeed, as shown in the figure below, dry FGD for Independence would be well within the range of cost-effectiveness that states and EPA have found to be reasonable. The table below reflects final BART FIP and SIP decisions for NO_x and SO₂ for coal-burning EGUs across the country, as reported in the respective decision-making documents. *See* Cost Reasonable Progress Effectiveness Spreadsheet, Ex. E. As EPA concluded in its September 27, 2016 FIP, the installation of dry FGD at Independence units 1 and 2 would reduce SO₂ pollution by 12,912 and 13,990 tons per year, respectively; resulting in a cost-effectiveness of \$2,853/ton and \$2,634/ton, respectively. 80 Fed. Reg. at 18,993, 81 Fed. Reg. 66,386. This is well within the range of costs that EPA and other states have typically considered cost-effective for reasonable progress controls.

B. ADEQ’s Rejection of Scrubbers Because of High Capital Costs is Arbitrary and Capricious.

In addition to the purportedly high cost-effectiveness of scrubbers, ADEQ cites the high capital costs of new scrubbers as a basis for declining to require them for Independence. Draft SIP at 47. Specifically, ADEQ asserts that “[r]equiring a technology that does not involve a significant capital investment that must be amortized over a long period also provides Entergy with the flexibility to determine the continued viability of Entergy Independence based on market conditions rather than extending the possible life of the units based on the need to recover the capital costs of Dry FGD.” *Id.* This claim is unfounded.

To begin, ADEQ assumes that Entergy would install new scrubbers to meet an emission limit based on the use of new scrubbers. But ADEQ provides no support for this assumption. BART determinations do not require the use of any particular technology. Rather, BART is usually stated as an emission limit, and a facility is free to employ any technology that meets the emission limit. Here, the existing FIP requires Independence to meet a SO₂ limit of 0.06 lb/MMBtu, but Entergy could meet that limit by either installing new scrubbers or by retiring the unit and replacing it with other generation sources. ADEQ arbitrarily failed to consider the possibility that Entergy would choose to meet a new SO₂ emission limit by retiring Independence, and that the capital costs of replacement generation might be lower than the costs of new scrubbers.

Moreover, ADEQ’s own analysis indicates that market forces have already made Independence unable to compete with cheaper gas-burning generation, and therefore it may be economically rational to retire Independence rather than install new scrubbers—thus avoiding

the problem of stranded costs that ADEQ asserts is the basis for rejecting scrubbers. ADEQ's analysis shows that Independence has run far less in recent years as a result of market trends that have favored natural gas over coal-burning generation. Draft SIP at 43-44. ADEQ states that "the economic pressure on coal units due to low natural gas prices is expected to continue throughout the rest of the 2008–2018 planning period and beyond." *Id.* at 43. Based on ADEQ's own analysis of market pressures that are making coal more expensive than natural gas, it is arbitrary for ADEQ to assume that the cheapest option for complying with a new SO₂ limit would be to install new scrubbers.

Finally, ADEQ appears to be claiming that scrubbers should not be required because Independence may otherwise retire prior to the 30-year period over which the costs of scrubbers are usually amortized. *See* Draft SIP at 47. This resembles the shorter remaining useful life analysis that ADEQ relies on in its BART analysis for White Bluff. But ADEQ has not proposed to make the retirement of Independence legally enforceable as part of the SIP, and therefore it is inappropriate to reject otherwise reasonable controls based on the mere possibility that Independence may operate for less than 30 more years.

C. ADEQ Improperly Relies on an Administrative Order that is Unsigned and Unenforceable.

As with White Bluff, ADEQ relies on provisions contained in an administrative order for compliance with reasonable progress requirements. Draft SIP, Attachment D. And just as the White Bluff Order is unlawful, so too the Independence Order is unlawful for multiple reasons. First, this Order is an unsigned draft which is insufficient to rely on for purposes of fulfilling the reasonable progress provisions under the Regional Haze Rule. Second, so-called "reasonable progress controls" are required as part of the long-term strategy, which "must include *enforceable* emissions limitations, compliance schedules, and other measures as necessary to achieve the reasonable progress goals established by States having mandatory Class I Federal areas." 40 C.F.R. § 51.308(d)(3) (emphasis added).

Moreover, the Draft SIP and the Order allow Entergy three years "to burn through existing stocks" of high-sulfur coal. If ADEQ is to select low sulfur coal, this technology is available regardless of existing stocks of dirtier, high sulfur coal.

D. ADEQ's Consideration of Visibility Improvement is Flawed.

In its reasonable progress analysis for Independence, ADEQ discusses "degree of improvement in visibility" under a separate heading, on par with the actual factors described in the Clean Air Act (at 46). ADEQ purports to apply this factor as a basis for not modeling the visibility impacts of its selected technology, low sulfur coal (*id.*). However, as ADEQ itself readily concedes, "degree of improvement in visibility" is not a statutory factor in a reasonable progress analysis (*id.*). Even if it were permissible to consider visibility improvement, ADEQ's consideration of visibility improvement is flawed.

First, ADEQ purports to consider visibility improvement, but does not even mention the visibility benefits of new scrubbers when it weighs all of the information it has considered. *See* Draft SIP at 47. Specifically, while ADEQ alleges that the cost-effectiveness and capital costs of

new scrubbers are too high, ADEQ does not mention the other side of the ledger: the benefits of scrubbers, and specifically the visibility benefits. It is arbitrary and capricious for ADEQ to purport to consider visibility improvement, but then not even weigh the visibility benefits against the costs of controls when making its control determination.

E. ADEQ’s Analysis of Whether Measures Are Necessary to Make Reasonable Progress at Missouri Class I Areas Violates the Regional Haze Rule.

ADEQ’s consideration of whether measures are necessary to mitigate Arkansas’s impacts to Class I areas in Missouri violates both the revised regional haze rule as well as the former version of the rule. Thus, regardless of which version of the haze rule applies here, ADEQ’s analysis of controls that could reduce impacts to Missouri Class I areas is unlawful.

The Regional Haze Rule revisions issued in 2017 specify how ADEQ must consider whether measures are needed to make reasonable progress at Class I areas outside Arkansas:

If a State contains sources which are reasonably anticipated to contribute to visibility impairment in a mandatory Class I Federal area in another State for which a demonstration by the other State is required under (f)(3)(ii)(A), the State must demonstrate that there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area that would be reasonable to include in its own long-term strategy. The State must provide a robust demonstration, including documenting the criteria used to determine which sources or groups of sources were evaluated and how the four factors required by paragraph (f)(2)(i) were taken into consideration in selecting the measures for inclusion in its long-term strategy.

40 C.F.R. § 51.308(f)(3)(ii)(B). As EPA noted in the 2017 revisions to the Regional Haze Rule, states have an “independent obligation to include in their SIPs enforceable emission limits and other measures that are necessary to make reasonable progress at *all* affected Class I areas, as determined by considering the four factors.” 82 Fed. Reg. 3078, 3095 (Jan. 10, 2017) (emphasis added).

The former version of the Regional Haze Rule contained the same core requirements, even if the language of the former haze rule differed slightly. Indeed, EPA made clear in the 2017 revisions that it intended merely to clarify existing Clean Air Act obligations that it believed had already existed for states to analyze measures for reducing impacts at out-of-state Class I areas.

For example, even before revising the Regional Haze Rule, EPA sought and was granted a voluntary remand to reconsider whether controls should be required at the Gerald Gentleman power plant in Nebraska to make reasonable progress at out-of-state Class I areas. *See Nebraska v. EPA*, No. 12-3084 (8th Cir. motion filed Feb. 6, 2015); *Nebraska v. EPA*, No. 12-3084 (8th Cir. order filed Mar. 19, 2015) (granting EPA’s motion for a voluntary remand). There, the State of Nebraska, and EPA itself, had relied on the same arguments that ADEQ makes here: that the neighboring state had not requested additional controls; and meeting the neighboring state’s

reasonable progress goal did not require additional controls. *See* 77 Fed. Reg. 40,150, 40,155-56 (July 6, 2012). EPA sought and the court granted a remand to reconsider this rationale for its reasonable progress control determination for the Gerald Gentleman plant. EPA's action indicates that even under the prior version of the Regional Haze Rule, EPA recognized that the arguments ADEQ advances here were flawed.

ADEQ's analysis of measures for making reasonable progress at out-of-state Class I areas is inconsistent with both the statute and the Regional Haze Rule. Where the Regional Haze Rule addresses "sources which are reasonably anticipated to contribute to visibility impairment in a mandatory Class I Federal area in another State" 40 C.F.R. § 51.308(f)(3)(ii)(B), and "other States cause or contribute to impairment in a mandatory Class I Federal area," *id.* § 51.308(d)(3)(ii), the proposal instead concludes that sources in Arkansas are not interfering with the achievement of Missouri's reasonable progress goals. Draft SIP at 51. ADEQ attempts to avoid the "contribute to visibility improvement" test by substituting a non-interference standard. This is a material difference because ADEQ's proposal admits that the contribution of Arkansas sources to light extinction at Missouri Class I areas has been projected to increase between 2002 and 2018. The ADEQ proposal fails to demonstrate that there are no additional emission reduction measures, for sources that contribute to out-of-state Class I area visibility impairment, that would be appropriate to include in the SIP, as required by the Regional Haze Rule.

As explained in our prior comments as well as the Stamper Report, there are control measures for Independence Units 1 and 2—namely, dry FGD—that satisfy all four of the reasonable progress factors and would significantly improve visibility at Missouri's Class I areas. ADEQ must require Independence Units 1 and 2 to meet an emission limit of 0.06 lb/MMBtu, based on the use of dry FGD, to improve visibility at Missouri's Class I areas.

F. ADEQ's Reasonable Progress Analysis Impermissibly Concludes that Controls Are Not Required Because the State is Currently On the Glidepath.

ADEQ unlawfully concludes that no additional controls are required at Independence in part because the state is on the "glidepath" toward natural visibility. As an initial matter, the glidepath is not an independently enforceable requirement. As EPA explained in its 2012 disapproval of Arkansas' regional haze SIP, which was never challenged, "[b]eing on the 'glidepath' does not mean that a state is allowed to forego an evaluation of the four statutory factors," as Arkansas did in its SIP. *See* 77 Fed. Reg. 14604, 14629 (Mar. 12, 2012).

That a Class I area is on "on the glidepath" does not relieve the state of conducting a reasoned analysis. To the contrary, EPA's long-standing interpretation of the regional haze rule is that "the URP does not establish a 'safe harbor' for the state in setting its progress goals." 79 Fed. Reg. 74,818, 74,834 (Dec. 16, 2014). If it is reasonable to make more progress than the URP, a state must do so, as EPA explained in the 1999 regional haze rule:

If the State determines that the amount of progress identified through the [URP] analysis is reasonable based upon the statutory factors, the State should identify this amount of progress as its reasonable progress goal for the first long-term strategy, unless it determines that additional progress beyond this amount is also reasonable. If the State determines that additional progress is reasonable based on

the statutory factors, the State should adopt that amount of progress as its goal for the first long-term strategy.

64 Fed. Reg. at 35,732.

V. THE DRAFT SIP AS A WHOLE VIOLATES THE CLEAN AIR ACT'S ANTI-BACKSLIDING PROVISION.

The SO₂ Draft SIP as a whole violates the Clean Air Act's "anti-backsliding" requirement, 42 U.S.C. § 7410(l), specifically applicable to reasonable further progress requirements. Compared to the existing federal plan, the State's plan would result in greater air pollution and worse visibility impairment at affected Class I areas. Section 110(l) of the Clean Air Act prevents a plan revision that would weaken the existing FIP requirements in this manner.

In the 2016 FIP, EPA determined that reasonable progress requires that Independence Units 1 and 2 meet SO₂ emission limits based on the use of new scrubbers. 81 Fed. Reg. at 68,319. Now, the State proposes a SIP that would replace those SO₂ emission limits with much higher limits based on the use of low-sulfur coal. In addition, whereas the existing FIP requires White Bluff Units 1 and 2 to meet SO₂ emission limits based on the use of new scrubbers, the proposed SIP revision would replace that requirement with a much higher emission limit as well as a vague and unenforceable administrative order. And the proposed SIP includes no reductions beyond those in the FIP that would compensate for allowing higher SO₂ emissions from both Independence and White Bluff.

As a result, and as shown in the table below, the proposed SIP would authorize significantly more SO₂ emissions and produce worse air quality than the existing FIP. The table below compares the total annual SO₂ reductions under EPA's 2016 FIP and the ADEQ SIP revision. As explained in the Stamper Report, ADEQ's SIP revision will not result in *any* emission reductions from Independence on an annual basis because the units are already achieving the 0.6 lb/MMBtu proposed emission limit.

Year	Total White Bluff + Independence SO₂ Emissions Under EPA's FIP, tpy²⁸	Total White Bluff + Independence SO₂ Emissions Under ADEQ's Proposed SIP, tpy²⁹	Increase in SO₂ Emissions with ADEQ's Proposed SIP Compared to EPA's Existing FIP, tpy
2020	62,293	62,293	0
2021	52,879	62,293	9,414
2022	5,807	62,293	56,486
2023	5,807	62,293	56,486
2024	5,807	62,293	56,486
2025	5,807	62,293	56,486
2026	5,807	62,293	56,486
2027	5,807	62,293	56,486
2028	5,807	62,293	56,486
2029	5,807	62,293	56,486
2030	5,807	62,293	23,973

This increase in SO₂ emissions under the SIP relative to the FIP violates the Clean Air Act's anti-backsliding provision, which provides that "[t]he Administrator shall not approve a revision of a plan if the revision would interfere with any applicable requirement concerning attainment and reasonable further progress . . . or any other applicable requirement of this chapter." 42 U.S.C. § 7410(l). Section 110(l) is the Act's "anti-backsliding" provision. *See El Comité Para el Bienestar de Earlimart v. EPA*, 786 F.3d 688, 692 (9th Cir. 2015). The anti-backsliding provision prohibits plan revisions that would interfere with attainment of the NAAQS or other "applicable requirements" of the Act. Section 110(l) prohibits plan revisions that would interfere with an existing requirement to make reasonable further progress, including

²⁸ The emissions for White Bluff and Independence are based on EPA's baseline emissions (from 2009-2013) and projected emission reductions found at 80 Fed. Reg. at 18,971 (Table 32) and 18,993 (Table 6). These reductions would begin in 2022, the compliance deadline under the 2016 FIP. Prior to that, emissions would be similar to EPA's baseline emissions at each unit. This assumes White Bluff ceases burning coal in 2030.

²⁹ Under ADEQ's SIP replacement, emissions will be identical to EPA's baseline emissions because on an annual average basis, the White Bluff and Independence units were not exceeding 0.6 lb/MMBtu. This assumes White Bluff ceases burning coal in 2030.

a BART determination, as the Act’s “applicable requirement[s]” include the regional haze program’s BART requirements. *See Oklahoma v. EPA*, 723 F.3d 1201, 1204, 1207 (10th Cir. 2013).

When determining whether a plan revision interferes with NAAQS attainment, EPA has interpreted section 110(l) as preventing plan revisions that would increase overall air pollution or worsen air quality. For example, the Eleventh Circuit has upheld EPA’s section 110(l) interpretation as prohibiting plan revisions that would increase emissions or worsen air quality. *Ala. Env’tl. Council v. EPA*, 711 F.3d 1277, 1293 (11th Cir. 2013) (EPA interpreted section 110(l) to “permit approval of the SIP revision ‘unless the agency finds it will make air quality worse’” (quoting 73 Fed. Reg. 60,957, 60,960 (Oct. 15, 2008))). In *Kentucky Resources Council, Inc. v. EPA*, 467 F.3d 986 (6th Cir. 2006), EPA interpreted section 110(l) as allowing the agency to approve a plan revision that weakened some existing control measures while strengthening others, but only “[a]s long as *actual emissions in the air are not increased.*” *Id.* at 995 (quoting 70 Fed. Reg. 28,429, 28,430 (May 18, 2005)) (emphasis added). The court upheld EPA’s interpretation, which “allow[ed] the agency to approve a [state implementation plan] SIP revision *unless the agency finds it will make the air quality worse.*” *Kentucky Resources Council, Inc. v. EPA*, 467 F.3d at 995 (emphasis added). The Seventh Circuit has also upheld EPA’s interpretation. *Indiana v. EPA*, 796 F.3d 803, 812 (7th Cir. 2015) (noting that EPA allows “emissions-increasing SIP revisions” if a state “identif[ies] substitute emissions reductions such that net emissions are not increasing.”). Moreover, in a short discussion regarding a challenge to the Nevada regional haze plan, the Ninth Circuit suggested that a haze plan that “weakens or removes any pollution controls” would violate section 110(l). *WildEarth Guardians v. EPA*, 759 F.3d 1064, 1074 (9th Cir. 2014).

In sum, by allowing both Independence and White Bluff to increase SO₂ emissions beyond what would be allowed under the existing FIP, the proposed SIP revision would increase air pollution and worsen air quality, in violation of the anti-backsliding provision of 42 U.S.C. § 7410(l).

VI. ADEQ HAS AN OBLIGATION TO CONSIDER THE PUBLIC HEALTH BENEFITS OF THE REGIONAL HAZE PROGRAM.

Contrary to ADEQ’s conclusory assertion that it need not consider the effect of SO₂ emissions on human health, the Arkansas Air Pollution Control Act provides that, “in exercising their powers and responsibilities under this chapter,” the agency “*shall* take into account and give consideration” among other things, the (1) “[e]ffect on normal human health of particular air contaminants and (2) [t]he interference with reasonable enjoyment of life by persons in the area and conduct of established enterprises that can reasonably be expected from air contaminants. Ark. Code Ann. § 8-4-312(9) & (12) (emphasis added). Moreover, the very purpose of the Clean Air Act is “to protect and enhance the quality of the Nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.” 42 U.S.C. § 7401(b)(1). Indeed, when Congress amended the Clean Air Act’s visibility provisions, it made clear that the paramount purpose and overriding commitment of the Act was the protection of public health and welfare. *See* H.R. Conf. Rep. 95-564, 1977 U.S.C.C.A.N. 1502, 1570. Thus, ADEQ has an obligation to consider the public health impacts of its proposal to

replace EPA's 2016 FIP with a SIP that effectively allows the largest Arkansas polluters to continue status quo operations.

The same pollutants that cause visibility impairment also cause significant public health impacts. According to EPA SO₂ "can harm the human respiratory system and make breathing difficult. Children, the elderly, and those who suffer from asthma are particularly sensitive" to its effects.³⁰ Moreover, SO₂ can penetrate deep into the lungs and cause a host of health problems, such as aggravated asthma, chronic bronchitis, and heart attacks.³¹ In 2005, EPA valued the regional haze program's health benefits nationally at \$8.4 to \$9.8 billion annually.³²

More specifically, EPA's regional haze plan for Arkansas would have decreased sulfur dioxide pollution from Arkansas EGUs by approximately 72,000 tons per year. 80 Fed. Reg. 18,971, 18,973, 18,993, 18,996. This pollution also causes significant public health impacts. Thus, EPA's plan would not only result in significant visibility improvements in Arkansas and Missouri Class I areas, but will result in significant, quantifiable benefits to human health across 14 states. *See* Thurston Decl. at 41-44. Indeed, using EPA-approved public health and air dispersion modeling, studies have demonstrated that the reductions in sulfur dioxide and associated fine particulate matter resulting from EPA's final rule would save 137 lives, prevent thousands of asthma events and hospitalizations, and avoid tens of thousands of lost work days *every year* that the controls are operational. *Id.* at 42, Tbl. 1. The total public health based economic benefits associated with the required pollution reductions will be at least \$1.3 billion annually across 14 states. *Id.*

Conversely, ADEQ's proposal to essentially allow Arkansas EGUs to continue emitting SO₂ at the same levels as those sources have been polluting for several years carries the risk of substantial harm to public health in Arkansas and neighboring states. ADEQ has an obligation to consider those public health impacts in finalizing any SIP. Ark. Code Ann. § 8-4-312(9) & (12).

VII. ARKANSAS LAW REQUIRES ADEQ TO SUBMIT THE REGIONAL HAZE SIP FOR LEGISLATIVE REVIEW BEFORE EPA'S FINAL APPROVAL.

Both Arkansas constitutional and statutory law require all state agencies to submit proposed rules for legislative review and approval. ADEQ's Draft SIP is plainly a rule within the meaning of state law, and therefore, ADEQ must submit it to the legislature through this process. Without legislative approval, the Draft SIP is illegal and invalid.

Arkansas has amended both its state constitution and administrative statutes to require legislative approval of new rules. Ark. Const. Art. 5, § 42 (incorporating Amendment 92); Ark. Code Ann. § 10-3-309. In particular, the Arkansas Constitution authorizes the General

³⁰ EPA, Health – Sulfur Dioxide, *available at* <https://www.epa.gov/so2-pollution/sulfur-dioxide-basics#effects>.

³¹ EPA, Health – Particulate Matter, *available at* <https://www.epa.gov/pm-pollution/health-and-environmental-effects-particulate-matter-pm>.

³² EPA, Fact Sheet – Final Amendments to the Regional Haze Rule and BART Guidelines, *available at* https://www.epa.gov/sites/production/files/2016-02/documents/fs_2005_6_15.pdf.

Assembly to establish a procedure for “the review by a legislative committee of administrative rules promulgated by a state agency before the administrative rules become effective,” and provides that “administrative rules promulgated by a state agency shall not become effective until reviewed and approved by the legislative committee.” Ark. Const. Art. 5, § 42(a)(1)–(2). The General Assembly implemented this authorization by statute in 2015, requiring all state agencies to file proposed rules with the Legislative Council at least thirty days before the expiration of the comment period, as provided under the state Administrative Procedure Act (APA) “or other laws or policies pertaining to the rulemaking authority of that state agency.” Ark. Code Ann. § 10-3-309(c)(1). Upon receipt, the Legislative Council will assign review of the rule to the Administrative Rules and Regulations Subcommittee, which will allow a period of public comment, after which a majority of a quorum of its members will initially vote on whether to hold a substantive vote to approve or disapprove of the rule. *See id.* § 10-3-309(c)(1)–(3). If the Subcommittee declines the initial vote (approving the rule by default), or approves the rule in the substantive vote, a majority of a quorum of the entire Legislative Council may then hold initial and substantive votes on whether to approve or disapprove the rule. *See id.* § 10-3-309(c)(4). Thus, upon completion of the Subcommittee’s first review, both bodies may decline to hold any vote, approving the rule by default. *See id.* § 10-3-309(c)(3)–(4). The statute additionally prescribes the standard under which the rule may be disapproved, as contrary to state or federal law or legislative intent, and either body may submit the rule to a committee of the General Assembly for its nonbinding recommendations. *See id.* § 10-3-309(f)–(g).

These legal requirements plainly require ADEQ to submit the proposed regional haze SIP for legislative approval. Both the statute and Subcommittee regulations define “state agency” broadly to include an office, commission, department, “or other agency of state government having authority to promulgate or enforce rules,” and neither lists ADEQ in their specific exclusions. *Id.* § 10-3-309(b)(2)(A)–(B).³³ “Rule” is also defined broadly, as “a state agency statement of general applicability and future effect that implements, interprets, or prescribes law or policy or describes the organization, procedure, or practice of a state agency *and includes without limitation the amendment or repeal of a prior rule.*” Ark. Code Ann. § 10-3-309(b)(1)(A) (emphasis added); *LC Rules*, Rule 22(a)(1)(A). The specific exclusions of rules requiring legislative approval only reach a statement “that concerns the internal management of a state agency *and that does not affect the private rights or procedures available to the public,*” declaratory orders, or intra-agency memoranda. Ark. Code Ann. § 10-3-309(b)(1)(B) (emphasis added); *LC Rules*, Rule 22(a)(1)(B) (lacking statutory exception for certain Medicaid codes). ADEQ’s failure to submit the proposed SIP for legislative approval violates state law, and is therefore illegal.

ADEQ cannot bypass this process by labeling elements of the SIP revision as mere “administrative orders” under Ark. Code. Ann. § 8-4-103(d)(4). *See* SIP Revision, Tab A p. 4. As an initial matter, that provision applies only to civil penalties, and it only applies to parties that “violate[] any provision of this chapter and regulations, rules, permits, or plans issued pursuant to this chapter.” Ark. Code. Ann. § 8-4-103(c)(1)(A) & (d)(1)(A). None of the sources at issue here have violated any provision of Arkansas’ regulations, and therefore the state lacks

³³ *Rules of The Arkansas Legislative Council* (hereinafter “LC Rules”), Rule 22(a)(2)(A)–(B) (adopted May 19, 2017) (<http://www.arkleg.state.ar.us/assembly/2017/Documents/ALC%20Rules%20-%20Amended%20May%2019%202017.pdf>).

authority to invoke section 8-4-103 to avoid the legislative process. Separately, declaratory orders under Arkansas law pertain to the enforcement or “*applicability* of any rule,” not to the *establishment* of a rule, which this SIP revision does. A.C.A. § 25-15-206 (emphasis added).

Moreover, ADEQ is not merely submitting a new regulation, but “asks that the EPA *withdraw* from the SIP” currently active Regional Haze regulations. Draft SIP at 12. The action therefore represents “the amendment or repeal of a prior rule,” which requires legislative approval “without limitation.” Ark Code Ann. § 10-3-309(b)(1)(A); *LC Rules*, Rule 22(a)(1)(A). Regardless of ADEQ’s preferred terminology, the action repeals a prior rule, and thus must be reviewed and approved by the Legislative Council.

Arkansas constitutional and statutory law require all state agencies, including ADEQ, to submit proposed rules to the Legislative Council for review and approval. Here, the state’s submission to EPA contains no indication that ADEQ has, in fact, complied with these requirements. Indeed, neither the legal authority nor the public review and consultation provisions of the SIP contain any reference to legislative consultation. Further, the agendas of the Administrative Rules and Regulations Subcommittee of the Arkansas Legislative Council since August of 2017 do not show any consideration of the Draft SIP.³⁴ Thus, ADEQ has not complied with the legislative review requirement, and the Draft SIP is invalid under Arkansas law.

CONCLUSION

For the foregoing reasons, the Draft SIP is arbitrary, capricious, and contrary to law, and therefore should be withdrawn.

Declaration of Bryan Sikes

Manager, Fleet Maintenance – Controls and Electrical, Entergy Services, Inc.

**DECLARATION OF BRYAN SIKES
IN SUPPORT OF MOTION TO STAY FINAL RULE OF THE
U.S. ENVIRONMENTAL PROTECTION AGENCY
BY ENTERGY ARKANSAS, INC., ENTERGY MISSISSIPPI, INC.,
ENTERGY POWER, LLC, AND ENERGY AND ENVIRONMENTAL
ALLIANCE OF ARKANSAS**

I, Bryan Sikes, hereby state as follows:

1. I am employed by Entergy Services, Inc. as Manager, Fleet Maintenance – Controls and Electrical. I am making this declaration in support of the motion by Entergy Arkansas, Inc. (“EAI”), Entergy Mississippi, Inc. (“EMI”), and Entergy Power, LLC (“EPI”) (collectively, the “Entergy Companies”), and Energy and Environmental Alliance of Arkansas (“EEAA”) to stay the final regional haze plan for Arkansas issued by the U.S. Environmental Protection Agency (“EPA”), titled “Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan” (“Final Rule”).
2. I am over 18 years of age, of sound mind, and in all respects competent to make this declaration.
3. I received a Bachelor of Science degree in Mechanical Engineering from the University of Arkansas at Fayetteville in 1994 and I am a registered Professional Engineer in the state of Arkansas. I have been employed by the company since 2004. I have held various positions at EAI and EMI, including Plant Engineer, Process Superintendent, Process Owner, and Production Superintendent. In my current position, at Entergy Services, Inc., I oversee a team of electrical and controls technical resources who provide project planning and execution support/oversight as well as power plant equipment and process subject matter expertise.

4. Entergy Services, Inc. provides administrative, accounting, legal, engineering, and other services primarily to the Entergy utility operating companies, including EAI and EMI. Entergy Services, Inc. is wholly owned by Entergy Corporation.
5. The Independence Steam Electric Station (“Independence”) is located in Newark, Arkansas, and has two coal-fired electric generating units, the 836-megawatt (“MW”) Unit 1 and the 842-MW Unit 2. Independence is owned by several co-owners, including EAI, EMI, and EPI, as well as several not-for-profit entities, such as Arkansas Electric Cooperative Corporation (“AECC”), East Texas Electric Cooperative, and the City of Osceola, and several members of EEAA, including the City of Conway, the City Water and Light Plant of the City of Jonesboro, and the City of West Memphis.
6. The White Bluff Electric Power Plant (“White Bluff”) is located in Redfield, Arkansas, and has two coal-fired electric generating units, the 815-MW Unit 1 and the 820-MW Unit 2. White Bluff is owned by several co-owners: EAI and several not-for-profit entities, such as AECC, and several members of EEAA, including the City of Conway, the City Water and Light Plant of the City of Jonesboro, and the City of West Memphis.
7. The Final Rule requires each coal-fired unit to meet a nitrogen oxides (“NO_x”) emission limit of 0.15 pounds per million British thermal units (“lb/MMBtu”) on a rolling 30-boiler operating day basis at loads of 50-100 percent of maximum heat input rating (the “full load limit”), and a rolling 3-hour average limit of 671 pounds per hour (“lb/hr”) at loads of less than 50 percent of maximum heat input rating (the “low load limit”). These emission limits are based on the installation of low-NO_x burners and separated overfire air (“LNB/SOFA”) on each unit. These limits must be met beginning April 27, 2018 (18 months after the effective date of the Final Rule).

8. To comply with the Final Rule, EAI must design, obtain preconstruction permits for, construct, install, and tune LNB/SOFA on all four units by April 27, 2018,¹ or cease operation of the units by that date.

Installation of LNB/SOFA

9. Installation of LNB/SOFA requires EAI to develop an application for and obtain, prior to construction, an air permit under the Clean Air Act's prevention of significant deterioration ("PSD") program; comply with the company's internal planning and prudence review procedures; complete a request for proposal ("RFP") process; select a vendor; procure equipment; schedule outages; install equipment; tune and test the equipment; and update the unit operating procedures and train staff to ensure proper operation of the equipment. For four units, this process would typically take well more than 18 months total.
10. EAI began implementing a truncated implementation schedule promptly after the Final Rule was issued, which required foregoing typical project steps. Physical installation of the LNB/SOFA equipment was completed at White Bluff Unit 2 on June 4, 2017, at Independence Unit 1 on October 20, 2017, and at Independence Unit 2 on December 19, 2017. However, tuning has not yet been completed at any of these units, as explained further below. Physical installation of the equipment at White Bluff Unit 1 is scheduled to commence in mid-January.
11. While physical installation of equipment has largely followed EAI's compressed schedule, the testing and tuning process is taking longer than expected due to unforeseen complications, thereby delaying the schedule for completion of the

¹ Although EAI already had obtained a preconstruction permit to install LNB/SOFA at White Bluff, and acquired the control equipment to do so on one unit at the time the Final Rule was published, a permit was still required to be obtained for Independence and equipment obtained for the second White Bluff unit and both Independence units.

project. EAI will not have sufficient time to appropriately tune the LNB/SOFA at White Bluff Unit 1 in the five- to six-week period that would be available between the completion of the physical installation of the equipment and the compliance deadline. Further, the controls that already have been installed on the other three units are not achieving the NO_x levels that were anticipated, particularly at low and high loads. EAI and its vendor continue to work on the controls to improve their performance, but it is unlikely that EAI will be able to fully comply with the NO_x limits by the deadline imposed by the Final Rule.

Compliance with the NO_x Emissions Limits

12. The White Bluff and Independence units are called on to operate by the Midcontinent Independent System Operation, Inc. (“MISO”) and are “load-following” units, which means that electricity generation varies over time in response to changes in consumer demand. As a result, they frequently operate at less than 50% capacity due to changes in electricity dispatch. The frequent operation at less than 50% capacity (“low load operation”) will make it difficult to comply with the NO_x emission limits in the Final Rule, even after installation of LNB/SOFA.
13. The Final Rule imposes a NO_x emission limit of 671 lb/hr on a rolling 3-hour average that applies when the White Bluff and Independence units are operating at less than 50 percent of their maximum heat input capacity. The 3-hour averaging period, which was introduced for the first time in the Final Rule, likely will result in exceedances of the limit in some operating conditions even after tuning of the required controls is complete. During periods of load transition and, in particular, periods of reduced load, NO_x formation is very sensitive to changing conditions such as air flow, fuel flow, and burner tilt position. When load is being ramped up or down, and mills are put in or out of service, NO_x emissions can

spike to levels well above typical for short periods of time. Within minutes of the excursion, NO_x emissions typically will return to and stabilize at the steady state level. Air permits and regulations normally take these equipment limitations, which occur even when best operational practices are followed, into consideration. With the short 3-hour averaging period, a single 15-minute spike in NO_x emissions could result in NO_x exceeding the low-load NO_x emission limit for a 3-hour period, even if the remaining 165 minutes were below compliance levels. A 30-boiler-operating-day averaging period is necessary to moderate the variations in NO_x due to load transition and low load.

14. The *level* of the low-load NO_x emission limit also is problematic. It offers no compliance margin, which is necessary to account for increased NO_x levels that occur as a function of low load operation, and the unavailability of the SOFA system when a unit is operated at less than 30 percent of capacity. When load falls below 50 percent, NO_x levels increase as a percentage of heat input, trending upwards as load is reduced. This phenomenon is due to the increased levels of excess air that are used to ensure safe boiler operation during low loads. During load swings, control systems lead load increases with increases in air flow and follow load decreases with reductions in air flow. This excess air leads to NO_x formation from nitrogen-laden air. Not only are NO_x emissions generated at a higher rate at low load, but NO_x control options are limited during these periods. SOFA cannot be employed when the boiler operates below 30 percent capacity, including during startup, because there is insufficient air to support both good combustion and maintain overfire air flow to the boiler. As a result, the SOFA system cannot provide any NO_x reduction during these operational periods. *See* Memorandum from Foster Wheeler (Nov. 22, 2016) (attached as Exhibit A).

15. The information gained to date from the currently ongoing tuning of the installed LNB/SOFA equipment indicates that the White Bluff and Independence units cannot achieve full compliance with the low-load NO_x emission limits across all operating conditions. Specifically, to date, based on EAI's review and analysis of the data, which is only available for two of the units so far, one of the units has only been able to meet the low load limit between 25% and 75% of the time. The other unit has had more success and has met the low load limit almost 94% of the time. Nonetheless, neither unit is consistently achieving compliance with the low load NO_x limit across all operating conditions.
16. The information gained from the currently ongoing tuning of the installed LNB/SOFA equipment also indicates that the full-load NO_x emission limit cannot be achieved at this time at all units across all operating conditions. Entergy's vendor has indicated that it may not be able to satisfy the performance guarantee while the unit simultaneously complies with its carbon monoxide ("CO") emission limit in its Prevention of Significant Deterioration permit. To date, one of the units for which data is available has only been able to meet both the NO_x and CO limits approximately 30 to 60% of the time. The other unit has been able to meet both limits approximately 70% of the time. Based on the available data, the units are far from consistently achieving compliance with the full load NO_x limit across all operating conditions.
17. Entergy is required to operate in compliance at all times, not just 25% or 75% or even 94% of the time. As a consequence of the issues identified above, if a stay is not granted, EAI likely will have to implement temporary operational restrictions to meet both the low load and full load NO_x limits. With tuning ongoing, the company has not yet determined the exact extent of those temporary operational restrictions, but any such limitations would result in decreased unit operating

efficiency and corresponding increased fuel costs and/or impact the ability of the plants to meet demand. If a stay of the NOx limits is not granted and EAI is forced to adopt temporary operational restrictions on the units to meet the NOx limits, EAI would suffer irreparable harm as the operating restrictions would have significant negative financial impacts for the company. *See* Declaration of Kurtis Castleberry, Entergy Arkansas, Inc., at ¶ 13.

I declare under penalty of perjury that the foregoing statements are true and correct based on my personal knowledge and information gathered and provided to me by the Entergy Companies' personnel and consultants.

Executed this 11th day of January, 2018.

A handwritten signature in black ink, appearing to read "Bryan Sikes", written over a horizontal line.

Bryan Sikes

Exhibit A

Memorandum from Foster Wheeler (Nov. 22, 2016)

11/22/2016

Attn: David Triplett

Amec Foster Wheeler Proposal No. 65-142232-00 Rev. 2

Reference: Entergy White Bluff/Independence - NOx Limitations at Reduced Load

Dear Mr. Triplett,

The following is intended to explain the limitations and issues associated with NOx reduction at reduced load, specifically below 50% of Maximum Continuous Rating (MCR).

First, it is important to understand how NOx is created in boilers and how specific boiler designs can result in increased NOx emissions at reduced load.

NOx Formation

There are two common mechanisms of NOx formation, thermal NOx and fuel NOx. Thermal NOx refers to the NOx formed through high temperature oxidation of nitrogen found in combustion air. The rate at which airborne nitrogen converts to NOx is a strong direct function of temperature and residence time at temperature and is generally known to contribute on the order of 20% of boiler exit NOx.

NOx is also formed from nitrogen in the fuel. When a carbon based fuel such as coal is burned, the elemental nitrogen is exposed to oxygen at high temperature converting it to NOx. Laboratory studies indicate that fuel laden nitrogen contributes approximately 80% of boiler exit NOx in boilers without firing systems designed specifically with NOx emissions in mind.

Regardless of origin, whether from air or in fuel, nitrogen will convert to NOx when temperatures exceed 2000°F in the presence of oxygen. Low NOx firing systems are therefore designed to minimize the duration and magnitude of peak flame temperatures in excess of this value while also keeping local levels of oxygen to a minimum.

Current NOx Emissions

Consider Figure 1 below, which is the NOx data reported to the EPA for Entergy White Bluff Unit 1 for the period from June 2015 to June 2016.

Figure 1 - EPA NO_x Emissions for White Bluff No. 1

The scatter data plotted above is the hourly input provided to the EPA over the past year; the black line is the average of that data. The red line represents the NO_x limit required by the Arkansas Regional Haze Federal Implementation Plan across the range from 25 to 100 percent heat input, which is 0.15 #/MMBtu from 50 to 100% of maximum load and 671 lb NO_x/hr (3-hour average) from 25 to 50% of maximum load (“NO_x FIP limit”).

The curve exhibits a NO_x trend that is typical of tangential (or corner-fired) boilers across their load range. Specifically, the amount of NO_x formed is fairly level from 50% (4,475 MMBtu/hr) to 100% heat input (8,950 MMBtu/hr) as a function of firing rate. However, below 50% heat input NO_x levels increase as a percent of heat input, trending upwards as load is reduced.

The heat input at less than 50% load is substantially reduced so the increase in NO_x does not come from nitrogen in the fuel, but from an elevated conversion of air laden nitrogen. This is largely an expected phenomenon because boilers firing at low loads use increased levels of excess air to keep boiler operation safe. Additionally, to keep boiler operations safe during load swings, control systems always lead load increases with air flow first and follow load decreases with reductions in air flow last. This control logic results in excess air above set point during all load swings, contributing further to NO_x formation, especially at low loads.

Proposed NO_x Control Solution

Entergy proposes to install low-NO_x burners and separated overfire air on all four White Bluff and Independence boilers to reduce NO_x emissions across the load range. Most suppliers will guarantee

performance of the overfire system across the load range from 50-100%; this range is typically known as the control range and is the range where overfire air is considered safe for use in reducing NOx.

Overfire air systems are based on the application of secondary air staging technology commonly referred to as “overfire air”. Staging of secondary combustion air has been well documented throughout the international boiler industry to be the single most effective technique for reducing NOx emissions from tangentially fired boilers. By redirecting a portion of the combustion air above the upper fuel elevation, fuel nitrogen conversion and thermal NOx production is normally reduced by more than 50%.

The systems being installed at White Bluff/Independence will feature the addition of a single level of separated overfire air to the boilers which already have overfire air in the main windbox.

White Bluff No. 1 Reheat Temperature Control

Most steam generator or boiler manufacturers use an increased amount of (excess) air in their boilers at reduced load to maintain steam temperatures.

However, tangential-fired boilers have a second unique method for controlling reheat steam temperature across the load range of the boiler. Specifically, the coal burners and secondary air nozzles can tilt vertically up or down from a horizontal position by 30 degrees. A downward tilt pushes the fireball lower in the furnace which increases furnace thermal absorption and reduces furnace exit gas temperature (FEGT). The converse is also true: tilting the coal burners upwards in the furnace increases the furnace exit gas temperature.

Based on Figure 1, it is apparent at reduced load that the increase in overall NOx is due to an increase in thermal NOx. This increase is being caused directly by main windbox tilt position, (most likely above horizontal to control reheat temperature), high excess air, and mills in service (upper elevation mills in service results in higher FEGT).

NOx Control at Reduced Load

When installed, overfire air systems are optimized for operation across the load range. The following is a typical curve for an overfire system installed on a tangential-fired boiler.

Figure 2 - SOFA Damper Control Curve

As can be seen from above, no overfire air is introduced to the boiler below 30% boiler load. This is because at reduced load, there is insufficient air to support both good combustion and maintain overfire air flow to the boiler. This means that the overfire system below this point does not provide any NOx reduction.

It should be noted here that the rate at which NOx is generated between the load points of 20 and 30 percent heat input is 2.38 times the rate between 30 and 50 percent. To alleviate issues with low load operation, the limit should increase from 671.25 #/hr to 895 #/hr. This change, which is reflective of the issues of instability at low load where separated overfire air is not available to use for NOx control, would then result in an FIP limit curve as shown in red below in Figure 3.

Figure 3 - NOx Generation at < 30% Load

With no overfire air system available to reduce NOx, the NOx reduction strategy at reduced load focuses on the direct causes of increased NOx: namely, up-tilt of the burner nozzles and high levels of excess air.

1.) Up-tilt of Coal Burners

To reduce NOx, the current burner tilts would have to be lowered below horizontal. This will reduce NOx emissions but will also result in reduced steam temperatures, causing a loss in boiler efficiency.

2.) Excess Air

The current boiler excess air levels would be reduced to promote NO_x reduction. Again, as with the burner tilts, this change will result in lower steam temperatures and reduced boiler efficiency.

All of these parameters will be optimized during the tuning process with the expectation of running with lower excess air levels and with tilts closer to horizontal. These factors alone will significantly reduce NO_x at this load, which is important because the NO_x reduction from the Tangential Low NO_x TLN system will be minimal due to a low mass flow of overfire air.

NO_x and Variable Load

NO_x concentrations remain relatively flat during periods of steady-state operation. However, during periods of load transition, and in particular at reduced load, NO_x is very sensitive to changing conditions such as air flow; fuel flow and burner tilt position. When load is being ramped up or down, and mills are put in or out of service, NO_x can spike to levels well above permitted values for short periods of time. Within minutes of the excursion, NO_x will typically return to and stabilize at the steady state level.

However, the issue lies with the duration of the reporting period: if the period is short (3-hours), the excursion in NO_x (which may last only 15 minutes) will result in an exceedance over the permitted 3-hour value as the spike in NO_x will not be averaged out by lower NO_x values achieved for the remaining 165 minutes. See Figure 4 below for an illustration of this time period.

Figure 4 - 3-hour NO_x Reporting Period

If the reporting period is longer, such as for the 30-boiler-operating-day limit for the high-load limit (50-100%) of the final FIP, then the occasional spike in NO_x due to load transition can be accounted for by

the majority of the reported NOx data being below permitted values. Figure 5 illustrates the impact of this longer reporting period.

Figure 5 - 30-Day NOx Reporting Period

Boiler Start-up

A systematic approach is required for the start-up of any boiler that has been out of service for a period of time. These approaches can vary depending on the boiler design, but all approaches are based on the same premise: safe start-up procedures that prevent damage to the equipment and ensure personnel safety.

To ensure safe start-up, certain procedures are in place: these include support fuel to ensure ignition of the coal, high excess air to promote stable combustion and up-tilt on the coal burners to push the combustion zone upwards in the furnace and promote an appropriate rise in temperature and pressure.

The National Fire Protection Agency (NFPA) also recommends that, on boilers fitted with overfire air systems, the “boiler shall be operating in a stable manner before the overfire is introduced.” This means that during boiler start-up, the overfire system is not in service and NOx is predominantly uncontrolled.

Unfortunately, all of the procedures in place to promote a safe boiler start-up are parameters that adversely impact NOx. It is not until stable combustion is achieved and the overfire air system is put into service that NOx can be controlled on a continuous basis.

Summary

Operation: Maintaining compliance at loads below 50% heat input will be difficult primarily due to the short reporting period. If compliance becomes troublesome, then following implementation of the NOx FIP limit, Entergy may have to institute new operating procedures that limit ramp rates or otherwise deviate from OEM recommended boiler operating practices. As has been stated, NOx control below 50% will be difficult, especially during boiler start-up and load swings, as the new overfire air system will be limited in its effectiveness because secondary air will almost entirely be directed to the main windbox for safe unit operation.

Reporting Period Duration: The swings that are normative at reduced load make the permitting levels difficult to achieve in short reporting periods. A single 15-minute spike in NOx could result in NOx exceeding the permitted level in a 3-hour reporting period, even if the remaining 165 minutes are under compliance levels.

In the case of a longer reporting period, e.g. 30 - boiler operating days, these same NOx spikes seen during load transition can be accommodated and NOx levels can be maintained below required reporting levels.

If you have any questions or require further information, please do not hesitate to contact Steve deMello (office: 908-713-2281) or myself.

Sincerely,

Kenneth McCarthy

**OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS**

MEMORANDUM

SUBJECT: Guidance on the Reasonably Available Control Measures (RACM) Requirement and Attainment Demonstration Submissions for Ozone Nonattainment Areas

FROM: John S. Seitz, Director
Office of Air Quality Planning and Standards

TO: Regional Air Division Directors
Regions I–X

Attached is guidance that clarifies EPA's policy on what constitutes "as expeditiously as practicable" for the purposes of attaining the national ambient air quality standards (NAAQS) for ozone nonattainment areas. The guidance contains information on EPA's determination of whether a State's submission provides for all RACM needed for attainment and whether implementation of those measures occurs as expeditiously as practicable. This guidance should be used by ozone nonattainment areas that are subject to the Clean Air Act requirement to submit an attainment demonstration and to submit RACM.

If you have any questions on this guidance, please contact Sharon Reinders at (919) 541-5284.

**Guidance on the Reasonably Available Control Measures
(RACM) Requirement and Attainment Demonstration
Submissions for Ozone Nonattainment Areas**

Preface

The purpose of this guidance is to set forth EPA's current interpretation of the relationship of the "as expeditiously as practicable" requirement and the attainment demonstration requirement for ozone nonattainment areas. While EPA intends to proceed under the guidance that it is setting out today, the EPA will finalize this interpretation only when it applies in the appropriate context of individual rulemakings addressing specific attainment demonstrations for ozone nonattainment areas. At that time and in that context, judicial review of the EPA's interpretation would be available.

Background

Sections 172(a)(2)(A) and 181 (a) of the Act require ozone nonattainment areas for to attain the ozone NAAQS as expeditiously as practicable and provide outer-limit dates for attainment based on an area's classification. Furthermore, section 172(c)(1), provides for "the implementation of all reasonably available control measures as expeditiously as practicable." This policy addresses how EPA interprets these requirements with respect to the adoption of control measures within the intrastate portion of the modeling domain for ozone nonattainment areas.

To ensure compliance with the Act, EPA will review each attainment demonstration submission for the ozone NAAQS to determine whether it provides for all RACM necessary to attain the standard as expeditiously as practicable and provides for implementation of those measures as expeditiously as practicable. The State's submission needs to contain sufficient information for EPA to make such determinations.

In order for the EPA to determine whether a State has adopted all RACM necessary for attainment as expeditiously as practicable, the State will need to provide a justification as to why measures within the arena of potentially reasonable measures have not been adopted. The justification would need to support that a measure was not "reasonably available" for that area and could be based on technological or economic grounds. Sources of potentially reasonable measures include measures adopted in other nonattainment areas and measures that the EPA has identified in guidelines or other documents.

In order for the EPA to determine whether an area has provided for implementation as expeditiously as practicable, the State must explain why the selected implementation schedule is the earliest schedule based on the specific circumstances of that area. Such claims cannot be general claims that more time is needed but rather should be specifically grounded in evidence of economic or technologic infeasibility. While it may be appropriate for some control measures to be implemented shortly after adoption, the EPA recognizes that other measures may need a longer period.

The EPA will review the State's submission to ensure that sufficient information is provided for the EPA to determine whether the State has adopted all RACM necessary for attainment as expeditiously as practicable and provided for implementation of those measures as expeditiously as practicable. The EPA will make those determinations based on the information provided by the State and any other information available to the EPA at the time the Agency approves or disapproves the attainment demonstration.

INTRODUCTION

In October 2017, the Arkansas Department of Environmental Quality (ADEQ) proposed a revision to its Regional Haze State Implementation Plan (SIP) to address portions of the Arkansas Regional Haze SIP that EPA disapproved on March 12, 2012.¹ This Technical Support Document provides a review and analyses of Regional Haze requirements for two sources addressed in ADEQ's proposed SIP revision: the White Bluff power plant (Units 1 and 2) and the Independence Power Plant (Units 1 and 2).²

I. Evaluation of ADEQ's Proposed Determination of Sulfur Dioxide Best Available Retrofit Technology (BART) for White Bluff Units 1 and 2.

On September 27, 2016, EPA finalized a regional haze Federal Implementation Plan (FIP) to address those portions of the Arkansas Regional Haze SIP that EPA disapproved on March 12, 2012.³ In the FIP, EPA proposed as best available retrofit technology (BART) for sulfur dioxide (SO₂) emissions at White Bluff Units 1 and 2 an emission limit of 0.06 lb/MMBtu based on installation of a dry flue gas desulfurization system (dry FGD) or other technology that achieves that same level of control.⁴ Compliance is required no later than 5 years from the effective date of EPA's rule, or by October 27, 2021.⁵ On April 25, 2017, EPA issued a temporary, 90-day stay of parts of the FIP in response to petitions for reconsideration filed by various entities.⁶ Among other things, EPA announced its granting of reconsideration of the SO₂ emission limits for White Bluff based on statements made by Entergy regarding the future operation of the White Bluff plant that arose after the close of the comment period on EPA's proposed FIP.⁷ However, after the 90-day stay expired in July 2017, there has been no further stay of the FIP requirements. As a result, Entergy is required to meet an SO₂ limit of 0.06 lb/MMBtu on a 30-boiler operating day average basis by October 27, 2021.⁸

At the request of ADEQ, Entergy prepared a new BART analysis for SO₂ for the White Bluff units which ADEQ is proposing to rely on in its October 2017 proposed rulemaking.⁹ Entergy made two significant changes to past BART analyses conducted for the White Bluff units. First, Entergy evaluated the burning of slightly lower sulfur coal as a control strategy to meet BART.¹⁰ Second, Entergy submitted revised cost effectiveness analyses for SO₂ controls

¹⁰ *Id.* at 22.

which assumed a shortened remaining useful life of coal-burning at the White Bluff units that varied between 7 to 9 years depending on the control technology being evaluated based on a planned date to cease burning coal at the units.¹¹ Based on this revised BART analyses, ADEQ determined that BART for SO₂ would be met by the use of low sulfur coal at White Bluff Units 1 and 2 to meet an SO₂ emission limit of 0.6 lb/MMBtu.¹² Below, I provide comments on Entergy's revised BART analysis and ADEQ's proposed SO₂ BART determination.

A. Based on the Draft Administrative Order in ADEQ's October 2017 Regional Haze Rulemaking Package, it Does Not Appear that ADEQ is Specifically Requiring Entergy to Cease Burning Coal at White Bluff Units 1 and 2.

As stated above, one of the primary justifications for this revised BART analysis is to take into account a shortened remaining useful life of coal-burning at the White Bluff units.¹³ In the un-redacted version of Entergy's August 2017 revised BART analysis which ADEQ made publicly available on December 18, 2017, Entergy stated it intended to cease the use of coal at White Bluff Units 1 and 2 by the end of 2028 and that it is prepared to take an enforceable restriction on its remaining useful life.¹⁴ However, in the draft Administrative Order applicable to Entergy that was included with the October 2017 rulemaking package, ADEQ did not specifically require that Entergy cease burning coal at White Bluff at all. Specifically, the draft Administrative Order states the following with respect to the White Bluff Units 1 and 2:

White Bluff Unit 1 (SN-01) and White Bluff Unit 2 (SN-02) shall comply with an emission limit of 0.6 pounds of sulfur dioxide per million British thermal units (0.60 lb/MMBtu) on a rolling 30-boiler-operating-day averaging period within three years of the effective date of this AO and with Entergy's execution of its intended changes to operations at the White Bluff facility Units 1 and 2 indicated in their comments to EPA's federal implementation plan of Aug. 7, 2015 cited in their Petition for Reconsideration dated Nov. 23, 2015 [fn omitted], no later than December 31, 2030.

Draft ADEQ Administrative Order for Entergy Arkansas, Inc. at Condition 3.¹⁵

Instead of directly requiring Entergy to cease burning coal at White Bluff Units 1 and 2 by a date certain, the Administrative Order requires Entergy to "comply...with Entergy's execution of its intended changes to operations...indicated in their comments to EPA's federal implementation plan of Aug. 7, 2015..."¹⁶ A review of Entergy's August 7, 2015 comments on

¹¹ See Entergy's August 18, 2017 Updated BART Analysis for SO₂ for White Bluff Units 1 and 2 at 4-4., un-redacted version made available by ADEQ in its December 18, 2017 Notice of Data Availability (hereinafter "August 18, 2017 White Bluff BART Update").

¹² October 2017 Public Review Draft at 25.

¹³ *Id.* at 24.

¹⁴ See August 18, 2017 White Bluff BART Update at 4-4.

¹⁵ In October 2017 Public Review Draft at pdf page 1776.

¹⁶ It appears the language in the Administrative Order is directing Entergy to its Aug. 7, 2015 comments to EPA but it could also be directing Entergy to its Nov. 23, 2015 Petition for Reconsideration.

EPA's FIP shows that Entergy told EPA "[a]s part of a multi-unit plan to improve visibility and to better manage its generation assets for reliability and costs, Entergy proposes to cease burning coal at White Bluff Units 1 and 2 by 2027 and 2028, one unit per year, and is prepared to take an enforceable commitment to that effect."¹⁷ It is not clear why ADEQ's draft Administrative Order does not instead refer to Entergy's more recent August 18, 2017 White Bluff BART Update that was submitted to ADEQ, which states that Entergy "anticipates Unit 1 and Unit 2 will cease to use coal by end of year 2028."¹⁸ In addition, there is a discrepancy between the draft Administrative Order and Entergy's updated BART analyses which ADEQ is relying on. Specifically, the draft Administrative Order states that Entergy shall comply with "execution of its intended changes to operations" at White Bluff Units 1 and 2 no later than December 31, 2030, but the cost effectiveness analyses in Entergy's Updated BART Analysis is based on the assumption that the White Bluff units will cease firing coal by December 31, 2028.¹⁹ It also is important to note that Entergy's August 18, 2017 BART Update seems to condition Entergy's willingness to take an enforceable date to cease firing coal at White Bluff upon "acceptance of the BART determinations contained herein in an approved SIP."²⁰ Thus, it seems that the vagueness of ADEQ's draft Administrative Order may be attempting to provide some flexibility to Entergy to address the possibility that Entergy might not cease firing coal at the White Bluff units by 2028 if EPA does not approve low sulfur coal to meet an SO₂ limit of 0.6 lb/MMBtu as BART.

EPA's BART Guidelines make clear that where the remaining useful life of a source affects the BART determination, the date the facility permanently stops operations "*must* be assured by a federally- or State-enforceable restriction preventing further operation."²¹ EPA's BART determination in its FIP promulgated on September 27, 2016 found that the installation of new dry scrubbers at White Bluff Units 1 and 2 to meet an SO₂ limit of 0.06 lb/MMBtu was justified to meet BART because the costs of controls were reasonable at \$2,565/ton SO₂ removed at Unit 1 and at \$2,421/ton SO₂ removed at Unit 2 in 2012 dollars (or \$2,377/ton and \$2,243/ton in 2016 dollars²²) and because these controls would result in "considerable visibility improvement."²³ EPA's BART determination was based on a 30-year life of the units.²⁴ Entergy assumed the same 30-year life in its 2013 BART analysis submitted to ADEQ, stating that "[t]he remaining useful life of [White Bluff Units 1 and 2] does not impact the annualized capital costs for either semi-dry scrubbing or wet scrubbing because the useful life of the units is anticipated to be at least as long as the capital cost recovery period, which is 30 years...."²⁵

ADEQ is now claiming in this proposed SIP revision that, with a shortened remaining useful life, dry scrubbers are no longer cost effective and thus ADEQ has proposed to find that dry scrubbers – or any other add-on SO₂ controls - are no longer justified as BART.²⁶

²⁵ October 14, 2013 Entergy White Bluff Revised BART Analysis at 5-7.

²⁶ October 2017 Public Review Draft at 24.

Accordingly, the remaining useful life of the White Bluff units must be assured by a federally- or state-enforceable restriction that clearly defines the end of the remaining useful life of the White Bluff units. The draft Administrative Order provided in the October 2017 ADEQ Regional Haze Rulemaking Package does not specifically require that Entergy shut down the White Bluff units or that Entergy cease burning coal at the White Bluff units by any date certain. Without a clearly enforceable date by which Entergy must shut down or cease burning coal at the White Bluff units, there is no basis for assuming a shortened remaining useful life in the SO₂ BART cost calculations. Thus, EPA's BART FIP requirements that each unit meet an SO₂ BART limit of 0.06 lb/MMBtu by October 27, 2021 are still justified because the controls are cost effective and would result in considerable visibility improvement.²⁷

Indeed, in the August 5, 2015 Technical Support Document of Conservation Organizations submitted to EPA in comments on its proposed FIP, I provided cost analyses for wet and dry FGD systems at White Bluff that also showed these controls were very reasonable at \$2,229/ton and \$2,526/ton (2012 \$) at White Bluff, Units 1 and 2 respectively, which were also based on a 30-year life of controls.²⁸ These costs would be \$2,065/ton and \$2,341/ton in 2016 dollars, based on changes in the CECPI index from 2012 to 2016. In the event ADEQ does not adopt an enforceable deadline by which Entergy must shut down or cease coal-firing at the White Bluff units in this proposed Regional Haze plan revision, I incorporate by reference and attach my August 5, 2015 report and relevant exhibits into these comments on ADEQ's proposed regional haze SIP rulemaking.²⁹

Assuming ADEQ does ultimately adopt an enforceable deadline by which Entergy must shut down or cease coal-firing at the White Bluff units in this proposed Regional Haze plan revision, I have prepared revised cost effectiveness analyses for dry FGD systems and also for dry sorbent injection (DSI) based on a shortened remaining useful life of controls. These analyses are discussed further below.

B. Entergy's Revised Cost Effectiveness Analyses for White Bluff Are Flawed and Do Not Demonstrate that the Costs of Add-on SO₂ Controls at White Bluff Units 1 and 2 Are Not Reasonable.

As previously stated, ADEQ is proposing in the October 2017 Regional Haze SIP rulemaking to find that SO₂ BART for White Bluff Units 1 and 2 would be met by the use of low sulfur coal at White Bluff Units 1 and 2 to meet an emission limit of 0.6 lb/MMBtu, based on Entergy's revised cost effectiveness analyses that, among other things, reflect a shortened remaining useful life of the White Bluff units.³⁰ ADEQ found that neither DSI nor dry FGD SO₂ control technologies would be cost effective with the shortened remaining useful life of the units assumed in Entergy's August 18, 2017 revised cost effectiveness analyses.³¹ Specifically,

²⁷ 40 C.F.R. 52.173(c)(6) and (7); 81 Fed. Reg. 66,332 at 66,343, 66,416.

²⁸ August 5, 2015 Technical Support Document to Comments of Conservation Organizations, EPA's Proposed Regional Haze and Interstate Visibility Transport Federal Implementation Plan for Arkansas, at 30-32.

²⁹ See August 5, 2015 Technical Support Document to Comments of Conservation Organizations (Ex. 1) at 28-34 and relevant exhibits to that report, which are included with Ex. 1.

³⁰ October 2017 Public Review Draft at 24, 25.

³¹ *Id.* at 23.

ADEQ relied on Entergy's revised cost effectiveness analyses that showed that dry FGD had an average cost effectiveness of \$5,403 per ton of SO₂ removed and DSI would have costs exceeding \$6,000/ton.³² ADEQ stated that the costs of these controls were "greater than what is typically considered cost effective."³³ However, Entergy's revised cost effectiveness numbers for dry FGD or even DSI are not outside the range of the costs of controls that similar sources have had to incur to meet BART. EPA's longstanding policy in evaluating costs of pollution controls is that, if other similar sources have had to incur similar costs to meet BART and regional haze control requirements, then those costs of control should not be considered unreasonable.

Data compiled by the National Park Service of State SO₂ BART determinations shows that the costs of SO₂ controls to meet BART at EGUs ranges from \$1,571/ton to as high as \$7,309/ton at the Silver Bay Power Plant in Minnesota.³⁴ In addition, EPA imposed a FIP of reasonable progress measures based on switching to a lower sulfur fuel oil at the fuel oil-fired boilers at the Kanoelehua Hill Power Plant, the Puna Power Plant, and the Shipman Power Plant in Hawaii at a cost effectiveness of approximately \$5,600/ton.³⁵ To address regional haze requirements for SO₂, the state of Wyoming found that a new dry scrubber and baghouse at Dave Johnston Unit 4 was cost effective at \$5,028 per ton of SO₂ removed.³⁶ Thus, cost effectiveness values in the \$5,000 per ton range for SO₂ BART are not out of the range that similar sources have had to incur to meet BART or reasonable progress.

Further, a review of the available information on Entergy's updated SO₂ cost effectiveness analyses shows that Entergy incorporated costs and methods would improperly inflate the cost effectiveness values for installing DSI or dry FGDs at each White Bluff unit as discussed below.

1. Entergy's Cost Effectiveness Evaluation of Low Sulfur Coal is Deficient.

Entergy's cost effectiveness evaluation for use of low sulfur coal (LSC) to meet an emission limit of 0.6 lb/MMBtu is deficient in several respects and also is inconsistent with how Entergy determined cost effectiveness for the add-on pollution controls evaluated, which makes all of Entergy's evaluations of the incremental cost effectiveness of add-on SO₂ controls inaccurate.

First, Entergy used a baseline period of 2009-2013, when it had previously used a baseline period of 2001-2003 in its 2013 BART analysis that EPA relied on, in part, in its FIP.³⁷ Entergy provided no basis for this change in baseline period. Entergy also evaluated a new control not previously evaluated of LSC to meet an emissions level of 0.6 lb/MMBtu.³⁸

³⁵ 77 Fed. Reg. 61,477, 61,490 (Oct. 9, 2012); see also 77 Fed. Reg. 31,691, 31,711-12 (May 29, 2012).

³⁶ See May 28, 2009 Wyoming Department of Environmental Quality BART Application Analysis, Dave Johnston Plant, at 23 (Ex. 3).

³⁷ See August 18, 2017 White Bluff BART Update at 1-1; see also 80 Fed. Reg. 18,969 (Apr. 8, 2015).

³⁸ August 18, 2017 White Bluff BART Update at 1-1, 4-1.

However, a review of the 2009-2013 annual average SO₂ rate based on emissions data submitted to EPA's Air Markets Program Database shows that each White Bluff unit had annual average emission rates less than 0.6 lb/MMBtu, with each unit's SO₂ rate averaging at 0.57 lb/MMBtu over the 2009-2013 timeframe.³⁹ Because cost effectiveness of a pollution control is measured on an annual basis, Entergy's evaluation of LSC based on a 2009-2013 baseline would not result in any reductions in SO₂ emissions on an annual basis and thus the cost effectiveness of LSC should be based on zero tons of SO₂ reduced. This is presumably why Entergy's consultant, Trinity Consultants, applied a different methodology to determining the tons of pollution removed in the cost effectiveness for LSC compared to how it determined the tons of pollution removed for the add-on SO₂ pollution controls. Specifically, Trinity states:

Trinity determined the values for annual tons of SO₂ reduced by subtracting the estimated controlled annual emission rate from the baseline annual emission rate. The baseline annual emission rate was based on the average rate for the 2009-2013 baseline period.[fn19] The controlled annual emission rates were based on the lb/MMBtu levels listed in Table 4-2 multiplied by the future annual heat input, which was based on the average actual heat input from CAMD for the 2009-2013 baseline period. *For the LSC scenario, "controlled" annual emission rates were based on an 8.75 percent decrease compared to baseline annual emission rates, which is estimated by comparing the maximum 30-boiler operating day rolling average to the controlled emission rate of 0.6 lb/MMBtu.*

August 18, 2017 White Bluff BART Update at 4-4 [Emphasis added].

By applying this different approach to calculating the reduction in emissions for LSC, the cost effectiveness value of using LSC was improperly inflated and should instead be zero if using a baseline of 2009-2013, because no SO₂ emissions would need to be reduced on an annual average basis to meet a 0.6 lb/MMBtu emission limit with LSC at White Bluff Units 1 and 2.

To compound the problem, Trinity used a different methodology for calculating emission reductions from add-on controls than it used for low-sulfur coal, using the typically-applied method⁴⁰ of reducing annual average baseline emissions by the percent reduction from the annual average baseline SO₂ rate in lb/MMBtu to the proposed SO₂ lb/MMBtu rate for each add-on BART control option. This means that comparisons between the emission reductions from add-on controls and low-sulfur coal are not apples-to-apples comparisons. Further, because Trinity calculated the tons of SO₂ reduced with DSI and a dry FGD based on a very different method than the method used for LSC, Trinity's determination of incremental cost effectiveness of either DSI or dry FGD compared to low sulfur coal is erroneous. ADEQ must ensure that cost effectiveness and incremental cost effectiveness for all controls evaluated are based on the same methodology for calculating annualized cost of control and annualized emission reductions. If Entergy is going to update its cost effectiveness analysis baseline to be based on 2009-2013, then the cost effectiveness of using LSC must be considered as zero since emissions won't be reduced

³⁹ See Ex. 4, spreadsheet with IPM Cost Models DSI Cost Analyses at tabs "WB 1 Baselines" and "WB 2 Baselines."

⁴⁰ 40 C.F.R. Part 51, Appendix Y, Section IV.D.4.c.

on an annual average basis, and all incremental cost effectiveness analyses need to be revised accordingly.

2. Entergy's Cost Effectiveness Analysis of DSI at 50% Control Is Based on Unrealistic Design Parameters that Would Tend to Overestimate Costs of Control.

Entergy's cost estimates for DSI developed by Sargent & Lundy at 50% control are overstated. First, in determining capital costs for the system, Sargent & Lundy designed the system based on 50% removal from a design inlet concentration of 0.76 lb/MMBtu, based on the highest 5% of SO₂ emissions from 2009-2013.⁴¹ Yet, in the 2009-2013 baseline period used in Entergy's cost effectiveness analyses, uncontrolled SO₂ averaged much lower at 0.57 lb/MMBtu on an annual average basis.⁴² Over a more appropriate baseline of 2001-2003 when the units burned somewhat higher sulfur coal, annual average uncontrolled SO₂ emissions still averaged only 0.69 lb/MMBtu at Unit 1 and 0.66 lb/MMBtu at Unit 2.⁴³ Cost effectiveness of pollution controls is to be based on an annualized cost effectiveness – that is the annual cost of controls divided by the annual tons of pollutant removed.⁴⁴ As such, the design and cost of controls should be based on the average annual reductions in SO₂ emission rate, not the highest 5% of SO₂ emissions over the baseline period.

Entergy has also proposed an SO₂ emission limit achievable with this control of only 0.35 lb/MMBtu based on a maximum 30-day average from 2014-2016 of 0.66 lb/MMBtu.⁴⁵ It is not clear why Entergy used 2014-2016 data when its cost analysis is based on a 2009-2013 baseline. Further, the 0.35 lb/MMBtu proposed SO₂ limit with DSI only reflects 47% SO₂ control from the maximum 30-day average from 2014-2016. Moreover, the proposed 0.35 lb/MMBtu limit only reflects 39% control from the 2009-2013 annual average baseline SO₂ emission rate of 0.57 lb/MMBtu. Thus, the capital and operating costs for the DSI system evaluated by Entergy are inflated based on the cost to reduce SO₂ by 50% from uncommonly high SO₂ rate for the White Bluff units and then the annual tons per year reduced are understated by basing the achievable emission limit on less than a 50% reduction in annual average SO₂ emissions.

Moreover, these and other unrealistic design considerations were carried over into an ESP upgrade that Sargent & Lundy stated may not even be needed at the White Bluff units with DSI at 50% control but yet included the costs in its DSI cost effectiveness analysis. Specifically, Sargent & Lundy's DSI analysis indicates that the ESPs at White Bluff Units 1 and 2 are large and operate at high removal efficiencies⁴⁶, and that the addition of DSI sodium compounds to the fly ash "lowers the overall resistivity of the particulate being captured as well as shifting the particle size distribution" which can "improve the removal efficiency of an ESP" in some cases

⁴⁶ *Id.* at 7 and in attachment of FuelTech's October 17, 2016 at 4.

enough to offset the increased particulate loading from DSI.⁴⁷ Yet, Sargent & Lundy included the costs of rebuilding the ESPs in the DSI cost effectiveness calculations.

Sargent & Lundy obtained an analysis of whether an ESP upgrade would be needed from FuelTech, who provided a cost estimate for an ESP rebuild that is included in Entergy's DSI cost analyses.⁴⁸ FuelTech determined that a complete ESP rebuild would be necessary due to the 22,500 lb/hr of trona injection, the inlet ash loading of 55,000 lb/hr, and a design outlet PM emission rate of 0.015 lb/MMBtu or lower.⁴⁹ As previously stated, the trona loading is based on an overly high uncontrolled SO₂ inlet rate reflective of the maximum 5% of uncontrolled SO₂ emission rates at the White Bluff units over 2009-2013. Thus, the trona injection rate of 22,500 lb/hr is higher than will likely be required at White Bluff Units 1 and 2. Moreover, an ash loading of 55,000 lb/hr reflects a much higher ash content coal than currently and historically used at White Bluff Units 1 and 2. Specifically, a review of coal used at the White Bluff units from the Energy Information Administration's coal data browser shows that the ash content of the coal used at the White Bluff units has generally been between 5-6% ash and sometimes even closer to 4% ash.⁵⁰ Based on EPA's AP-42 emission factors for uncontrolled coal, an approximate average heat value of the coal used at White Bluff of 8600 Btu/lb⁵¹, and a maximum hourly heat input to each boiler of 8950 MMBtu/hr⁵² and assuming 5.5% ash content, the particulate loading to the ESPs at the White Bluff units would be significantly lower at 28,620 lb/hr.⁵³

Not only was FuelTech's estimate that an ESP rebuild would be needed with DSI at each White Bluff unit based on an overly high ash and trona loading to the ESP, but FuelTech also assumed the outlet PM emission rate had to be 0.015 lb/MMBtu or lower.⁵⁴ The White Bluff units are subject to a much higher PM emission limit of 0.10 lb/MMBtu.⁵⁵ Sargent & Lundy relied on EPA program ESPVI 4.0W to claim that the White Bluff ESP operates at a control level to meet a filterable PM emission limit of 0.0155 lb/MMBtu,⁵⁶ yet the units are instead subject to a PM emission limit that is more than 6 times higher than 0.0155 lb/MMBtu. While it is understood that Entergy would want to ensure that actual PM emissions do not increase above PSD significance levels and trigger PSD permitting⁵⁷, Entergy does not need to reduce PM emissions to avoid PSD. Yet, that is how Sargent & Lundy asked FuelTech to evaluate the need for ESP upgrades and for design of the ESP upgrades. Entergy's BART Update did not even include stack test data to show what filterable PM emission rates the White Bluff units are actually emitting. Stack test data from 2010 show that Unit 1 was emitting filterable PM at

⁵⁶ Sargent & Lundy, White Bluff DSI Cost Estimate Basis Document, August 3, 2017 at 6.

⁵⁷ As stated in Sargent & Lundy, White Bluff DSI Cost Estimate Basis Document, August 3, 2017, at 2.

0.019 lb/MMBtu⁵⁸ and Unit 2 was emitting filterable PM at 0.016 lb/MMBtu, both of which are higher than FuelTech’s design outlet emissions rate of 0.015 lb/MMBtu or lower.⁵⁹ Based on these unrealistic design parameters, FuelTech determined that retrofits to the White Bluff ESPs would be required and that the ESPs would need to be built to “‘as-new’ condition with the most state-of-the-art technology options.”⁶⁰ FuelTech estimated a total cost for materials and installation of \$50,000,000 per unit, more than half of Sargent & Lundy’s direct capital cost estimate for DSI at each White Bluff unit.⁶¹

In summary, Sargent & Lundy’s assumptions, and the unrealistic design parameters behind those assumptions, added significantly to the cost estimates for DSI to achieve 50% control from the highest uncontrolled SO₂ emission rates at White Bluff Units 1 and 2 and by assuming a complete ESP retrofit would be required, when it is not even clear that any changes to the ESP will be required to meet the proposed SO₂ emission rate of 0.35 lb/MMBtu.

3. Entergy’s Cost Analysis of “Enhanced DSI” is Also Based on Design Parameters that Would Overestimate Costs of Control.

In evaluating DSI at higher SO₂ removal rates, Entergy evaluated the addition of a baghouse along with DSI, a control option Entergy labelled “Enhanced DSI.”⁶² As with its evaluation of DSI, Entergy’s cost estimates for Enhanced DSI developed by Sargent & Lundy are overstated. First, in determining capital costs for the system, Sargent & Lundy designed the system based on 80% removal from a design inlet concentration of 0.76 lb/MMBtu, based on the highest 5% of SO₂ emissions from 2009-2013.⁶³ Yet, in the 2009-2013 baseline period used in Entergy’s cost effectiveness analyses, uncontrolled SO₂ averaged much lower at 0.57 lb/MMBtu on an annual average basis.⁶⁴ Over a more appropriate baseline of 2001-2003 when the units burned somewhat higher sulfur coal, annual average uncontrolled SO₂ emissions still averaged only 0.69 lb/MMBtu at Unit 1 and 0.66 lb/MMBtu at Unit 2.⁶⁵ Cost effectiveness of pollution controls is to be based on an annualized cost effectiveness – that is the annual cost of controls divided by the annual tons of pollutant removed.⁶⁶ As such, the design and cost of controls should be based on the average annual reductions in SO₂ emission rate, not the highest 5% of SO₂ emissions over the baseline period.

⁵⁸ See Source Emissions Survey of Entergy Services, Inc. White Bluff Steam Electric Station Unit Number 1 Stack (SN-01), April 2010, at 2 (Ex. 6).

⁶³ Sargent & Lundy, White Bluff Enhanced DSI Cost Estimate Basis Document, August 3, 2017, at 2, included in Entergy’s August 2017 White Bluff BART Update.

⁶⁴ *Id.*

⁶⁵ See Ex. 4, Spreadsheet with IPM Cost Models DSI Cost Analyses, at tabs “WB 1 Baselines” and “WB 2 Baselines.”

⁶⁶ See 40 C.F.R. Part 51, Appendix Y, Section IV.D.4.b. and c.

Entergy has also proposed an SO₂ emission limit achievable with this control of only 0.15 lb/MMBtu based on a maximum 30-day average from 2009-2013 of 0.66 lb/MMBtu.⁶⁷ The 0.15 lb/MMBtu proposed SO₂ limit only reflects 77.3% SO₂ control from the maximum 30-day average from 2009-2013. Moreover, the proposed 0.15 lb/MMBtu limit only reflects 73.7% control from the 2009-2013 annual average baseline SO₂ emission rate of 0.57 lb/MMBtu. Yet, the Enhanced DSI system reagent injection rates were based on 80% control.⁶⁸ Thus, the capital and operating costs for the DSI system evaluated by Entergy are inflated based on the cost to reduce SO₂ by 80% from uncommonly high SO₂ rate for the White Bluff units and then the annual tons per year reduced are understated by basing the achievable emission limit on less than a 80% reduction in annual average SO₂ emissions. Consequently, Entergy's cost effectiveness values for enhanced DSI at White Bluff Units 1 and 2 are likely inflated.

4. ADEQ Must Ensure that the Cost Effectiveness Analyses Relied on for its Revised BART Determinations Are Not Based on Costs that EPA Does Not Allow in BART Cost Effectiveness Analyses.

EPA requires that BART cost determinations be based on the methodology of EPA's Control Cost Manual.⁶⁹ However, it appears Entergy does not agree with EPA's requirement, and it is not clear whether the cost effectiveness numbers being relied on by ADEQ comport with the methodology of EPA's Control Cost Manual.

Entergy provided two summary tables of cost effectiveness analyses of SO₂ controls in its 2017 White Bluff BART Update: "Summary of SO₂ Controls Cost Effectiveness for Unit 1 and Unit 2 Based on Actual Costs" in Table 4-3 of Entergy's August 18, 2017 submittal and "Summary of SO₂ Controls Cost Effectiveness for Unit 1 and 2 *Based on Costs Adjusted for EPA-Exclusions for Illustration Purposes*" in Table 4-4 of Entergy's August 18, 2017 submittal to ADEQ [Emphasis added]. The cost effectiveness values listed in ADEQ's October 2017 Public Review Draft and associated documents appear to indicate that ADEQ is relying on the cost effectiveness numbers "Adjusted for EPA-Exclusions" in Table 4-4 of Entergy's August 18, 2017 BART Update⁷⁰, although ADEQ does not state this directly. While it appears that Entergy's adjusted costs for EPA exclusions did not include "Allowance for Funds Used During Construction" (AFUDC)⁷¹ it is unclear if all other costs were excluded that are not consistent with the costing methodology of EPA's Control Cost Manual.

⁶⁷ Sargent & Lundy, White Bluff Enhanced DSI Cost Estimate Basis Document, August 3, 2017, at 2, included in August 18, 2017 White Bluff BART Update.

⁶⁸ *Id.*

⁶⁹ See 40 C.F.R. Part 51, Appendix Y, Section IV.D. under Step 4.a. Impact analysis part 1: How do I estimate the cost of control?

⁷⁰ October 2017 Public Review Draft at 23. See also spreadsheet in ADEQ files with filename "wb-cost-calcs" in which ADEQ calculates the annualized costs, average cost effectiveness, and incremental annualized costs that were redacted in Table 4-4 of Entergy's August 18, 2017 White Bluff BART Update based on the incremental cost effectiveness data and tons of SO₂ removed. Thus, it is clear that ADEQ is relying on Entergy's cost calculations that excluded AFUDC and possibly other costs not allowed by EPA.

⁷¹ August 18, 2017 Entergy Updated BART Five-Factor Analysis for SO₂ for Units 1 and 2 at 4-5.

EPA requires that BART cost determinations be based on EPA's Control Cost Manual to have a consistent basis for comparison to other States' BART cost determinations.⁷² This is very important because, as EPA has done for years with BACT determinations, the costs that other subject-to-BART sources have had to bear to comply with regional haze requirements are used as a benchmark for determining if the cost of pollution control at a source in question is reasonable.⁷³ In other words, if other similar sources have had to bear similar costs for a particular control technology to meet BART, then such costs should be considered reasonable for another source of the same source category, taking into account other factors that define BART including the degree of improvement in visibility expected to result with the pollution control. The only way such comparisons can be properly made is with the consistent use of the same cost methodology.

The costing methodology of the Control Cost Manual is based on the "overnight" method of cost estimation, widely used in the utility industry.⁷⁴ The overnight method is the cost of a construction project if no interest is incurred during construction, as if the project is completed "overnight." The overnight cost is the present value cost that would have to be paid as a lump sum up front to completely pay for a construction project.⁷⁵ The overnight costing methodology converts the capital cost estimates into an annual cost in current real dollars without any inflation. The overnight costing methodology must be used regardless of the source of the capital cost data. The only exceptions are as to the source of capital cost estimates – vendor quotes, equipment bids, budget estimates.

This overnight method is uniformly used in regulatory cost effectiveness analyses specifically so cost effectiveness is meaningful. There are no alternate cost methodologies for determining cost effectiveness. This issue is well settled and has consistently been EPA's position on cost effectiveness analyses for BART and reasonable progress determinations. *See*, for example, EPA's responses to comments on the Oklahoma Regional Haze Plan, the EPA's BART determination for the San Juan Power Plant, and correspondence with North Dakota regarding BART.⁷⁶

It appears that Entergy's cost effectiveness analysis that it is relying on is based on an entirely different "all in" costing methodology, which seek to determine the actual cost to the owner. These methods inflate costs to future build date, include taxes, interest, bond charges, allowance for funds used during construction (AFUDC), and other cost components, which in the real world may be incurred, but are irrelevant and inappropriate for a regulatory cost effectiveness analysis. A regulatory cost effectiveness analysis does not seek to determine owner

⁷² See 40 C.F.R. Part 51, Appendix Y, Section IV.D. under Step 4.a. Impact analysis part 1: How do I estimate the cost of control?

⁷³ See October 1990, New Source Review Workshop Manual, U.S. EPA, at B.29.

⁷⁴ See Cost Control Manual, Section 2.3 to 2.4.

⁷⁶ See Response to Technical Comments for Sections E. through H. of the Federal Register Notice for the Oklahoma Regional Haze and Visibility Transport Federal Implementation Plan, 12/13/2011 [Docket ID EPA-R06-OAR-2010-0190-0057 in docket for the Oklahoma FIP] Ex. 8; U.S. EPA, Complete Response to Comments for NM Regional Haze/Visibility Transport FIP, 8/5/2011, EPA-R06-OAR-2010-0846-0127 (Ex. 9); and May 10, 2010 Letter from Andrew M. Gaydosh, Assistant Regional Administrator, EPA Region 8, to Terry O'Clair, Director, Division of Air Quality, North Dakota Department of Health, Re: EPA's Comments on the North Dakota Department of Health's April 2010 Draft BACT Determination for NOx for the Milton R. Young Station, at 14-16 (Ex. 10).

costs, but rather to compare costs among similarly-situated sources by using a method that involves the smallest amount of guesswork possible. The overnight method eliminates guessing what future prices, inflation rates, and taxes, for example, will be and instead relies only on what everyone can discover today, currently, in real-time, and real dollars, when the estimate is being prepared.

In its cost estimates provided in Table 4-4 of its August 18, 2017 BART Update, i.e., “Costs Adjusted for EPA-Exclusions for Illustration Purposes,” which ADEQ appears to rely on, Entergy does not state what other costs aside from AFUDC were excluded from the costs in its Table 4-4 of its August 18, 2017 BART Update. It is difficult to determine whether Entergy excluded other “all-in costs” that would not be allowed in overnight cost method of the Control Cost Manual that it did take into account in its detailed cost estimates presented in its August 2017 BART Update. For example, escalation of costs during construction, which takes into account changes in labor and material prices over the time period of construction, are not be allowed in the overnight costing method of the Control Cost Manual which, as stated earlier, is to reflect the present value of the cost to construct a project as if construction were completed overnight.⁷⁷ Further, EPA does not consider owner’s costs to be valid costs under its Control Cost Manual.⁷⁸ In addition, if Entergy took into account the sales tax cost of controls, ADEQ must not allow the sales tax to be included if Arkansas offers an exemption for sales taxes for construction of pollution control equipment as is allowed in many states.

ADEQ must ensure to the public that the Entergy cost numbers it is relying on for its Regional Haze SIP revision do not include escalation of costs during construction, owner’s costs, AFUDC, or other costs not allowed by the overnight costing method.

5. Entergy Appropriately Assumed Compliance with DSI Could Occur by 2019 for DSI and Entergy Should Have Assumed an October 27, 2021 BART Compliance Date for a Dry FGD System.

In determining the remaining useful life of the White Bluff units to calculate annualized capital costs of controls, Entergy’s updated BART analysis assumes DSI would be installed and operating by the end of 2019 and that dry FGD systems would be installed and operating by the end of 2021.⁷⁹ It was appropriate for Entergy to assume a 2019 compliance date for DSI, which can be installed quite readily as is discussed below. However, Entergy should not have assumed a compliance date for installation of dry FGD systems any later than the current BART compliance date of EPA’s FIP of October 27, 2021 (40 C.F.R. §52.173(c)(7)). Thus, if ADEQ adopts an enforceable requirement mandating that White Bluff Units 1 and 2 shut down or cease burning coal by December 31, 2028 as proposed by Entergy⁸⁰, then a remaining useful life of 7 years and 2 months (or 7.17 years) should be used in the revised cost analyses for dry FGD

⁷⁷ See 81 Fed. Reg. 66,332 at 66,383 (Sept. 27, 2016). See also EPA’s Response to Comments on its FIP at 336, 338, and pdf page 341-343 (Ex. 11).

⁷⁸ As stated in EPA’s final Arkansas FIP at 81 Fed. Reg. 66,383 (Sept. 27, 2017).

⁷⁹ Entergy’s August 18, 2017 BART Update at 4-4.

⁸⁰ *Id.* Note that Entergy’s August 7, 2015 comments to EPA, which ADEQ cites to in its draft Administrative Order, stated that Entergy proposed to cease all coal-fired operations at one White Bluff unit by 2027 and at the other unit by 2028. See August 7, 2015 Entergy Comments to EPA at 2, 5.

systems. While Entergy may claim that dry FGD systems would require an additional 5 years after adoption of the SIP revision, dry FGD systems have been installed more readily than 5 years. There are numerous examples of SO₂ pollution controls being installed in less than 5 years.

During the adoption of the Mercury and Air Toxics Standards (MATS), EPA found that EGUs could install required controls, including scrubbers, within 3 years. Specifically, EPA stated in 2011 that “[u]nits that choose to install dry or wet scrubbing technology should be able to do so within the compliance schedule required by the [Clean Air Act] as this technology can be installed within the 3-year window.”⁸¹ In support of this claim, EPA referenced a letter to Senator Carper dated November 3, 2010, in which David Foerter, executive director of the Institute of Clean Air Companies (ICAC), stated that wet scrubbers could be installed in 36 months, dry scrubbing technology could be installed in 24 months, and dry sorbent injection could be installed in 12 months.⁸² ICAC’s claims were based on 7 years of pollution control installation at coal-fired EGUs under the Clean Air Interstate Rule (CAIR) and under the NO_x SIP Call. The ICAC letter states that, between 2008 to 2010, flue gas desulfurization (FGD) controls were installed at numerous EGUs with combined capacity of 60 gigawatts (GW) while, concurrently, selective catalytic reduction was installed at roughly 20 GW of EGUs.⁸³ During that timeframe of significant pollution control installation, there were no labor shortages.⁸⁴

In analyses conducted for the MATS rule, EPA similarly found that there were significant FGD and SCR retrofits in recent years, and stated:

These data depict a recent ramp-up in the [Air Pollution Control] deployment capabilities of all industry participants, including plant owners, the [Air Pollution Control] supply chain, and state and local permitting agencies. These expanded [Air Pollution Control] capabilities are still active today...⁸⁵

The compliance deadline for the MATS rule was April 2015, with the possibility of a one-year extension until April 2016. Because those deadlines are past, there should not be labor shortages for installing SO₂ controls to meet EPA’s proposed SO₂ BART requirements at the White Bluff plant.

EPA’s predictions regarding MATS provided to be true, as many scrubbers were installed to meet MATS within three to four years, at most. Table 1 below provides several examples of EGUs which are in the process of installing SO₂ scrubbers and which will be completed within three to four years.

Karn Plant (SRN B2840) Units 1 & 2 for Compliance with the Mercury and Air Toxics Standard (40 CFR 63 Subpart UUUUU) and the Michigan Mercury Rule (R336.2501) at 2 (Ex. 15). Exact date of scrubber startup obtained from EPA’s Air Markets Program Database.

⁸⁸ See July 9, 2014 TVA – Gallatin Fossil Plant (GAF) – Request for Compliance Extension - Mercury and Air Toxics (MATS), Enclosure at page 4 (Ex. 16). Based on information in EPA’s Air Markets Program Database, Unit 4’s FGD became operational in April of 2015, Unit 3’s FGD was operational in April 2015, and Unit 2’s FGD was operational in January 2016.

⁸⁹ See November 5, 2013 Request for One-Year Extension of the Compliance Deadline for the Mercury and Air Toxics Standards and of the Expiration Date of the Plan Approval for the Installation of Flue Gas Desulfurization Units at 1-2 (Ex. 17). Based on information in EPA’s Air Markets Program Database, Homer City Unit 1’s FGD was operational in October 2015 and Unit 2’s FGD was operational in April 2016.

⁹⁰ See October 4, 2012 Construction Extension for Consumers Energy Company’s JH Campbell Facility Pursuant to the Mercury and Air Toxics Standard (40 CFR 63 Subpart UUUUU, also known as MATS) as well as the Michigan Mercury Rule (R336.2501, *et seq.*), Exhibit B, Figures B-1c and B-1d (Ex. 18). Based on information in EPA’s Air Markets Program Database, J H Campbell Unit 2’s FGD was operational in May 2016 and Unit 3’s FGD was operational in August 2016.

⁹¹ See “Hitachi Power Systems America Awarded Contract to Supply Pollution Controls Equipment for KCP&L.” (Ex. 19).

⁹² See June 22, 2012 Request for Extension of the Mercury and Air Toxics Standards (MATS) Compliance Deadline KCP&L La Cygne, Source ID No. 1070005, at 1 (Ex. 20). Based on information in EPA’s Air Markets Program Database, La Cygne Unit 1’s FGD was operational in March 2015 and Unit 2’s FGD was operational in October 2014.

IN	Michigan City	12	Planning for the dry FGDs began in 2011 with final operation scheduled for 1 st quarter 2016 for Unit 12. ⁹³
IN	RM Schahfer	14, 15	Co-located with the Michigan City Plant, FGD systems were installed and became operational at Unit 14 on November 1, 2013 and at Unit 15 on October 26, 2014 according to CAMD. ⁹⁴

For those plants that will have multiple units at which scrubbers are to be installed under EPA’s proposed BART rulemaking, those plants will benefit from coordinated and shared engineering design and FGD fabrication, economies of scale benefits with FGD suppliers, and more consistent staffing levels with on-site contractors for concurrent FGD installations.⁹⁵ This is demonstrated in the table above. For example, the Gallatin plant had four FGDs installed within approximately four years from design to operation.

With respect to White Bluff, Entergy presumably should have been planning for installation of dry scrubbers to meet an SO₂ limit of 0.06 lb/MMBtu at White Bluff Units 1 and 2 since at least 2013, when it first proposed such controls to ADEQ and EPA to meet BART.⁹⁶ EPA’s BART FIP requiring the White Bluff units to meet a 0.06 lb/MMBtu SO₂ limit was promulgated by EPA on September 27, 2016.⁹⁷ Given that Entergy initially proposed to install dry FGDs at White Bluff Units 1 and 2 in 2013, one would presume that Entergy has already had some of the engineering work completed to know that it was reasonable and feasible for the company to propose to install dry scrubbers to meet an SO₂ limit of 0.06 lb/MMBtu. In any event, Entergy could realistically meet the October 27, 2021 BART compliance deadline for installation of dry FGD systems and the remaining useful life should have been based on that start date of dry FGD systems in the cost analysis for those controls.

It was appropriate for Entergy to assume a 2019 compliance date in determining the remaining useful life of dry sorbent injection. Indeed, DSI systems can be designed and installed very quickly, in as little time as 1 year according to the Institute of Clean Air Companies.⁹⁸ For example, the R Gallagher power plant in Indiana was required to install dry sorbent injection systems pursuant to a settlement with the U.S. Department of Justice after a federal jury found in May 2009 that Duke Energy made modifications to Gallagher Units 1 and 2 that were not properly permitted.⁹⁹ According to information in EPA’s Air Markets Program Database, DSI was installed and operational at Gallagher Unit 2 in November 2010, about 1.5 years after the

⁹³ See January 30, 2013 NIPSCO – Michigan City and R.M. Schahfer Generation Stations Request for Extension of Time to Comply with the Utility MATS NESHAP at 1. (Ex. 21). Based on information in EPA’s Air Markets Program Database, Michigan City Unit 1’s FGD was operational in November 2015.

⁹⁴ See EPA’s Clean Air Markets Database for RM Schahfer. See also January 30, 2013 NIPSCO – Michigan City and R.M. Schahfer Generation Stations Request for Extension of Time to Comply with the Utility MATS NESHAP at 1 (Ex. 21).

company was found to have modified the unit without proper permitting. As another example, the Boardman Power Plant in Oregon was required to install dry sorbent injection to meet BART despite its enforceable requirement to shut down by December 31, 2020. In June 2012, it was announced that the Shaw Group Inc. was awarded a contract to engineer, procure and construct a DSI system and balance of plant equipment.¹⁰⁰ According to information in the Air Markets Program Database, the DSI system was installed and operating by July 2014, or about two years after the contract was awarded for engineering and construction of a DSI system. This was also 3.5 years from the date of Oregon's final adoption of the BART requirement to install DSI at Boardman¹⁰¹ and 3 years from the date of EPA's final approval of the Boardman BART requirements.¹⁰²

Even if a baghouse is required with the DSI system, baghouses have been installed in less than five years as well. It could very well be that only a polishing baghouse would be required downstream of the existing ESP, which can be designed, delivered and installed fairly readily. For example, a polishing baghouse for the Lon D. Wright power plant in Nebraska was designed and delivered within 18 months and then installed in a planned outage.¹⁰³ If the ESP had to be replaced with a baghouse, that can be accomplished in less than five years. For example, in April 2008, PacifiCorp applied for an air permit to, among other things, replace the existing ESP at Huntington Unit 1 power plant in Utah with a baghouse, and that permit had a planned date for installation of the baghouse to be completed by November 22, 2010 (i.e., 2.5 years from submittal of a construction permit application).¹⁰⁴ According to information in EPA's Air Markets Program Database, the baghouse began operating by November 2010 at Huntington Unit 1 as originally projected. The Big Stone Power Plant converted an existing ESP to a baghouse over a period of approximately 2 years.¹⁰⁵

In summary, Entergy and ADEQ should have based the remaining useful life for determining annualized cost of dry FGD systems based on the current BART compliance date of October 27, 2021. There is ample justification that a dry scrubber could be installed by October 27, 2021. Assuming ADEQ adopts an enforceable requirement for White Bluff Units 1 and 2 to shut down or cease firing coal by December 31, 2028, the remaining useful life assumed in the BART cost analyses should be no shorter than 7.17 years (7 years and 2 months). And for the cost analysis of DSI, it was entirely appropriate for Entergy to assume that such controls could be installed by December 31, 2019, even if a baghouse is required.

C. Revised Cost Effectiveness Analyses Using Cost Spreadsheets Relied upon by EPA in Other Rulemakings Demonstrate that Add-on SO₂ Pollution Controls Are Still Cost Effective Even with a Shortened Remaining Useful Life of White Bluff Units 1 and 2.

In this section of the comments, I provide cost effectiveness analyses for SO₂ BART at the White Bluff units to address some of the issues identified above with Entergy's analyses. For illustration purposes only, I have calculated the cost-effectiveness of DSI and FGD using several remaining useful life periods for White Bluff. To be clear, given that none of the remaining useful life periods I use below are currently enforceable, it is not appropriate to use any of these remaining useful lives in a BART analysis.

For the purposes of these analyses, the following periods of remaining useful live were assumed:

- 1) a 9.17 year remaining useful life which reflects BART compliance by the October 27, 2021 deadline of the current FIP and which assumes ADEQ adopts an enforceable requirement explicitly requiring that the White Bluff units either shut down or cease firing coal by December 31, 2030;
- 2) a 7.17 year remaining useful life which reflects BART compliance by the October 27, 2021 FIP deadline and which assumes ADEQ adopts an enforceable requirement that the White Bluff units cease firing coal by December 31, 2028, consistent with Entergy's proposed date for cessation of coal-firing at the White Bluff units¹⁰⁶;
- 3) a 5 year remaining useful life to reflect the claim made by Entergy's consultant Trinity Consultants in the August 2017 BART Update report that installation of a dry FGD system may take until 2023¹⁰⁷ and which assumes that ADEQ adopts an enforceable requirement that Entergy cease firing coal at the White Bluff units by December 31, 2028; and
- 4) for DSI, an 11 year remaining useful life which reflects compliance by December 31, 2019 as Entergy's revised BART analysis assumed for this control¹⁰⁸ and assuming ADEQ adopts an enforceable requirement for the White Bluff units to cease burning coal by December 31, 2030. If ADEQ adopts an enforceable requirement for the White Bluff units to cease firing coal by December 31, 2028 as Entergy has proposed, then my analysis using a 9.17 year life is generally reflective of DSI cost effectiveness based on compliance by 2019 and cessation of coal-firing by 2028.

If ADEQ does not adopt an enforceable deadline for shutting down or ceasing coal-burning at White Bluff Units 1 and 2, then the remaining useful life of the units should not be considered as limited in the cost effectiveness analyses. As previously shown by EPA in its FIP and in my August 5, 2015 Technical Support Document, the costs of dry FGD systems to meet an SO₂ limit of 0.06 lb/MMBtu assuming a 30-year life are reasonable at approximately \$2,200

¹⁰⁶ August 18, 2017 White Bluff BART Update at 4-4.

¹⁰⁷ *Id.* at 4-4, footnote 18.

¹⁰⁸ *Id.* at 4-4.

to \$2,600/ton (2012 dollars), or \$2,040/ton to \$2,400/ton in 2016 dollars¹⁰⁹, and are justified given the “considerable visibility improvement” that is expected from such controls.¹¹⁰

For the cost effectiveness analyses presented herein, I focused the same control options that Entergy/ADEQ evaluated but with some additional analyses specifically related to DSI. Entergy’s August 2017 BART Update evaluated the following add-on pollution controls to meet BART:

- Dry FGD to meet an SO₂ limit of 0.06 lb/MMBtu
- DSI to achieve 50% control from 2001-2003 baseline rates
- DSI to achieve 80% control from 2001-2003 baseline rates
- DSI plus a retrofit baghouse to achieve 80% control from 2001-2003 baseline rates

More detail on why these controls were evaluated as BART will be provided below.

The emissions and operational data for the years 2001-2003 were used to estimate baseline emissions for the BART controls options at White Bluff Units 1 and 2, rather than the 2009-2013 baseline as used by Entergy in its August 18, 2017 BART Update. As discussed above, Entergy’s more recent 2009-2013 baseline reflects the level of low sulfur coal on an annual basis that the company and ADEQ are evaluating as a BART option (the “LSC” BART option). Because Entergy and ADEQ are proposing LSC as a BART option to achieve 0.6 lb/MMBtu and because the annual average SO₂ rate at White Bluff Units 1 and 2 over 2009-2013 is lower than 0.6 lb/MMBtu, use of an earlier baseline is the more appropriate way to properly evaluate LSC as a control option, particularly in comparison to other BART control options. This is consistent with how EPA has evaluated BART for sources that installed controls after the typical 2000-2004 baseline period but before EPA proposed action on the regional haze plan. Specifically, in other BART evaluations where a source has installed low NO_x burners and overfire air before the BART determination, EPA has evaluated NO_x BART based on a baseline period from before the installation of the pollution controls.¹¹¹

Moreover, use of a 2001-2003 baseline period is most consistent with the baseline period that EPA has stated is to be used for baseline visibility conditions in EPA’s regional haze rules. As EPA stated in its July 1, 1999 regional haze rulemaking:

After considering public comments on the baseline issue, EPA has determined that the most appropriate “baseline period” would be a fixed, 5-year period extending from calendar year 2000 through calendar year 2004. The EPA concluded that a standard baseline period provides for greater national consistency in establishing this important value, and therefore, is preferable to a provision allowing the baseline period to be a variable number of years. Using a common number of years and data points to calculate the baseline value for each

site is consistent with fundamental statistical principles and will provide for easy comparison of data from multiple sites as the program is implemented.

64 Fed. Reg. 35728 (July 1, 1999).

While this regional haze requirement primarily pertains to baseline visibility conditions to determine the necessary rate of progress to attain natural background visibility conditions by 2064, EPA's "consistency" rationale requires that the baseline for the BART cost analysis cover a similar period. That way, when one is evaluating BART, one is evaluating both the costs and the visibility benefits of getting from the same baseline levels of emissions to the controlled emission level being evaluated as BART.

For determining the cost effectiveness of dry FGDs and DSI, I prepared revised cost analyses using SO₂ control cost spreadsheets that EPA used in the 2016 and 2017 Texas Regional Haze and BART rulemakings.¹¹² EPA's SO₂ control cost spreadsheets were, in turn, based on the Sargent & Lundy IPM cost modules for dry FGD and DSI systems.¹¹³ EPA used these cost modules in its cost evaluation of SO₂ controls for several EGUs in Texas. I modified EPA's SO₂ cost spreadsheets used in the Texas Regional Haze rulemaking for use in this Arkansas Regional Haze rulemaking, basing cost effectiveness calculations on the 2001-2003 annual average SO₂ emissions (in tons per year and lb/MMBtu), heat input, capacity factor, and gross generation.¹¹⁴

EPA has relied on these cost modules of the Integrated Planning Model for BART and reasonable progress determinations in several states including Arizona, Wyoming, Montana, and Texas.¹¹⁵ In addition, EPA has relied on the IPM cost modules for Selective Catalytic Reduction in its Control Cost Manual.¹¹⁶ The algorithms of the IPM cost modules were based on actual cost data of retrofit pollution controls and other studies and evaluations of costs of a control. For

example, for the wet FGD cost module, Sargent & Lundy based its cost algorithms on regional planning organization data, studies commissioned by the utility industry, published papers, and Sargent & Lundy's in-house data from 2007 to 2012.¹¹⁷ For the DSI cost module, the primary cost is the cost of the sorbent. Thus, the proper determination of the Normalized Stoichiometric Ratio (NSR) based on the uncontrolled SO₂ at the unit and the desired removal efficiency is the key to a projection of the costs of these controls.¹¹⁸ All of the SO₂ control cost modules require EGU-specific data on size, type of coal, heat rate, current SO₂ rate, etc. to ensure that the cost of the controls is refined to be specific to the SO₂ removal needs of each unit.¹¹⁹

The IPM cost modules are sufficiently grounded in real costs for SO₂ pollution control retrofits for EGUs, while still being tailored to the specifics of each EGU that would affect SO₂ removal. The IPM cost modules are considered as appropriate for a study-level cost estimate, as required by EPA's Control Cost Manual, and are therefore appropriate to use in this BART analyses for White Bluff Units 1 and 2. However, some modifications are needed to the IPM cost modules to make the cost effectiveness calculations consistent with the methodology of the Control Cost Manual.

In the Texas cost spreadsheets developed by EPA from the IPM cost modules, EPA modified the cost modules to be consistent with the overnight costing method of the EPA's Control Cost Manual. For example, although the IPM cost modules include owner's costs and Allowance for Funds Used During Construction (AFUDC), EPA did not include those costs in its cost effectiveness analysis.¹²⁰ EPA also added algorithms for calculating annual costs and annual emissions reductions with each control, so that average cost effectiveness is calculated for each control and unit evaluated. For annualizing capital costs, EPA assumes a 7% interest rate, and I have assumed the same 7% interest rate for these cost calculations.

For determining annualized costs of a baghouse at each White Bluff unit, which I evaluated with the costs of DSI to achieve 80% SO₂ removal, I made cost projections using the Sargent & Lundy IPM Model Particulate Control Cost Development Methodology.¹²¹ The example calculations and algorithms from the Sargent & Lundy baghouse cost documentation were input into a spreadsheet. Then, projected annualized costs were calculated for White Bluff Units 1 and 2 based on the specifics of each unit, assuming a 7% interest rate and a varying remaining useful life as was assumed for the DSI and dry FGD controls. The cost algorithms for a baghouse to be used as a sole particulate capture system, with an air-to-cloth ratio of 4.0, was used for these analyses (as opposed to a higher air-to-cloth ratio system that reflects a polishing baghouse). Sargent & Lundy indicate that the lower air-to-cloth ratio "will provide for better fabric filter bag life with the high inlet particulate loading expected for the single particulate capture device in the process."¹²² The annualized costs of DSI at 80% control were then added

¹²² *Id.* at 4.

to the annualized cost of a full-scale baghouse at each unit to arrive at a cost per ton of SO₂ removed for DSI plus a baghouse to achieve 80% control.

For DSI, I evaluated cost effectiveness for 50% control and at 80% control, consistent with the SO₂ removal efficiencies assumed in Entergy’s analysis of DSI. These are also the removal efficiencies that EPA has evaluated in other cost evaluations of DSI with ESPs.¹²³ For the 80% control scenario, I evaluated DSI both with and without the addition of a full-scale baghouse. My evaluation of DSI with a retrofit baghouse at 80% SO₂ removal was done to directly compare to Entergy’s “Enhanced DSI” BART control option, which was also based on DSI plus a baghouse to achieve 80% reduction in SO₂.¹²⁴ For dry FGD, I estimated cost effectiveness to achieve an emission limit of 0.06 lb/MMBtu, which is the currently required BART limit of EPA’s FIP based on the installation of a dry FGD system.¹²⁵ The results of my cost calculations are provided in the tables below.

Table 2. SO₂ Control Cost Effectiveness Evaluations for White Bluff Units 1 and 2 Based on IPM Cost Modules, a 2001 – 2003 Baseline, and a Remaining Useful Life of 9.17 Years¹²⁶

White Bluff Unit	SO ₂ Control	Total Annualized Costs, 2016\$	Tons SO ₂ Removed	Cost Effectiveness, 2016 \$/ton	Entergy’s Cost Effectiveness of DSI Based on 2011-2015 Baseline, 9 year life, 2016 \$/ton ¹²⁷
1	Dry FGD	\$58,382,308	17,995 tpy	\$3,244	-----

¹²³ EPA’s FIP for Texas Regional Haze at 81 Fed. Reg. 296 (Jan. 5, 2016) (Final Rulemaking); 79 Fed. Reg. 74,817 (Dec. 16, 2014) (Proposed Rulemaking). See also EPA’s Texas BART determinations at 82 Fed. Reg. 912 at 925 (Jan. 4, 2017) (Proposed Rulemaking); 82 Fed. Reg. 48324 (Oct. 17, 2017) (Final Rulemaking)

¹²⁴ August 18, 2017 White Bluff BART Update at 4-2 and Sargent & Lundy, White Bluff Enhanced DSI Cost Estimate Basis Document, August 3, 2017, at 2, included in Entergy’s August 2017 White Bluff BART Update

¹²⁵ 40 C.F.R. 52.173(c)(6) and (7); 81 Fed. Reg. 66,416 (Sept. 21, 2016).

¹²⁶ See Spreadsheets at Ex. 4 (IPM Cost Models DSI Cost Analyses at tabs “WB 50%” and “WB 80%” (under Option A)), Ex. 31 (IPM Cost Models Baghouse plus DSI 80 Percent Cost Analyses at tabs “WB 1 9.17 yr life” and “WB 2 9.17 yr life”); and Ex 32 (IPM Cost Models Dry FGD Cost Analyses at tabs “WB 1” and “WB 2” (under Option A)).

¹²⁶ August 18, 2017 White Bluff BART Update at 4-5 (Table 4-4, Summary of SO₂ Controls Cost Effectiveness for Unit 1 and Unit 2 Based on Costs Adjusted for EPA-Exclusions for Illustration Purposes). As stated above, it appears that ADEQ is relying on Entergy’s costs numbers adjusted for EPA-exclusions in its current rulemaking.

¹²⁷ *Id.* Note that only Entergy’s cost effectiveness numbers for DSI are included here for comparison purposes, because those are the only controls evaluated based on a 9 year life (i.e., compliance by 2019, cessation of coal-firing by 2028).

The above cost effectiveness numbers reflect a compliance date of October 2021 and an enforceable shutdown date of December 31, 2030. However, the analyses for DSI cost effectiveness are consistent with the installation of DSI by October of 2019 and shutdown/cessation of burning coal by December 31, 2028 as assumed by Entergy in its revised BART analysis for DSI¹²⁸, although the remaining useful life assumed by Entergy was 9 years rather than 9.17 years shown above. As will be discussed further below, all of these costs are reasonable, in that other similar sources have had to bear similar costs for pollution control to address BART and regional haze requirements.

These control options are also cost effective when evaluated on a shorter remaining useful life. Table 3 below provides the cost effectiveness analyses for the same suite of controls as shown in Table 2 above with a 7.17 year remaining useful life, which assumed compliance by October 2021 and that ADEQ adopts an enforceable requirement that White Bluff cease coal-firing by December 31, 2028.¹²⁹ This is consistent with how Entergy evaluated cost effectiveness for dry FGD systems in its August 2017 updated BART analyses.¹³⁰ The cost effectiveness calculations were calculated in the same manner as was described for Table 2 (i.e., 2001-2003 baseline, Sargent & Lundy cost spreadsheets revised to be consistent with the EPA's Control Cost Manual, etc.), with the only change being that the annualized capital costs were based on a shorter remaining useful life of only 7 years (reflective of compliance with BART by October 21, 2023 and assuming an enforceable requirement to shut down or cease burning coal by December 31, 2028).

¹²⁸ August 18, 2017 White Bluff BART Update at 4-4.

¹²⁹ *Id.*

1	DSI at 50%	\$25,288,056	9,858 tpy	\$2,565
2	DSI + BH at 80%	\$48,072,433	13,606 tpy	\$3,533
2	DSI at 80%	\$40,277,354	13,606 tpy	\$2,960
2	DSI at 50%	\$22,416,912	8,504 tpy	\$2,636

All of these cost evaluations summarized in Tables 2 through 5 above show that the cost effectiveness of SO2 controls, even with an enforceable remaining useful life as short as five years, are not outside the range of costs that similar sources have had to bear to meet BART and

¹³⁴ See Spreadsheets at Ex. 4 (IPM Cost Models DSI Cost Analyses at tabs “WB 50%” and “WB 80%” (under Option C)), Ex. 31 (IPM Cost Models Baghouse plus DSI 80 Percent Cost Analyses at tabs “WB 1 5 yr life” and “WB 2 5 yr life”); and Ex. 32 (IPM Cost Models Dry FGD Cost Analyses at tabs “WB 1” and “WB 2” (under Option C)).

¹³⁵ 82 Fed. Reg. 926 (Jan. 4, 2017), Table 10.

regional haze requirements. Data compiled by the National Park Service of State SO₂ BART determinations shows that the costs of SO₂ controls to meet BART at EGUs ranges from \$1,571/ton to \$7,309/ton.¹³⁶ While the cost effectiveness of dry FGD systems and DSI plus a baghouse are on the high end of this range for a remaining useful life of 7.17 years (more so at White Bluff Unit 2 than at White Bluff Unit 1), the cost of SO₂ controls based on the Sargent & Lundy IPM cost modules even with the remaining useful life assumed by Entergy of approximately 7 years are not outside the range of costs that similar sources have had to bear to meet BART. For example, EPA imposed a FIP of reasonable progress measures based on switching to a lower sulfur fuel oil at the fuel oil-fired boilers at the Kanoelehua Hill Power Plant, the Puna Power Plant, and the Shipman Power Plant at a cost effectiveness of approximately \$5,600/ton.¹³⁷ To address regional haze requirements for SO₂, the state of Wyoming found that a new dry scrubber and baghouse at Dave Johnston Unit 4 was cost effective at \$5,028 per ton of SO₂ removed.¹³⁸ EPA based its SO₂ BART determination for the Flint Creek Unit 1 in Arkansas on installation of a NID™ circulating dry scrubber, finding that a cost of \$3,845 per ton was a reasonable cost,¹³⁹ and ADEQ has concurred in its current Regional Haze rulemaking that a NID™ scrubber at a cost effectiveness of \$3,845 per ton was cost effective. EPA approved installation of a dry FGD at the Colorado Springs Nixon Unit 1 as a reasonable progress measure at a cost effectiveness of \$3,744/ton.¹⁴⁰ Oregon required the Boardman power plant to install DSI to meet SO₂ BART at a cost effectiveness of \$3,370/ton, which was based on the enforceable commitment to cease firing coal by December 2020.¹⁴¹

The projected costs for these SO₂ controls at the White Bluff units are also comparable to costs for NO_x controls that EPA and states have found to be reasonable to meet BART. Colorado found that the costs of SCR at Hayden Units 1 and 2 were reasonable at \$3,385/ton and \$4,064/ton, respectively.¹⁴² In its final action on the Wyoming regional haze plan, EPA found that costs for SCR plus low NO_x burners and overfire air ranging from \$2,635/ton to \$4,461/ton (2008 dollars), or \$2,480/ton to \$4,200/ton in 2016 dollars, were reasonable to require SCR as BART at Naughton Unit 3, Dave Johnston Unit 3, and at Laramie River Units 1, 2, and 3.¹⁴³ EPA also approved Wyoming's adoption of reasonable progress requirements for each of the Jim Bridger units to install SCR at a cost effectiveness ranging from \$2,743/ton to \$3,403/ton, \$ in 2013 dollars, or \$2,619/ton to \$3,249/ton in 2016 dollars.¹⁴⁴ In its FIP for Arizona regional haze, EPA required SCR along with combustion controls to meet BART at the BART-subject coal-fired units at Apache, Cholla, and Coronado power plants at cost effectiveness values up to \$3,450/ton.¹⁴⁵ Moreover, the state of Arizona has stated that a cost effectiveness value of more

¹³⁸ See May 28, 2009 Wyoming Department of Environmental Quality BART Application Analysis, Dave Johnston Plant, at 23 (Ex. 3).

¹³⁹ Note that this cost projection developed in 2012 was projected to be based on 2016 dollars, and EPA found that projecting based on a future build date is not acceptable for a BART analysis. None-the-less, EPA found that a cost effectiveness of \$3,845/ton was reasonable to justify the NID™ CDS to meet BART at Flint Creek. 67 Fed. Reg. 18,944 at 18,965-7 (Apr. 8, 2015). *See also* final rulemaking on Arkansas BART at 81 Fed. Reg. 66,332 at 66,387, 66,416 (Sept. 27, 2016).

than \$4,489/ton of NO_x removed is cost effective.¹⁴⁶ EPA Region IX has required SCR as BART for the Four Corners Units 1 - 5 to meet a NO_x limit of 0.11 lb/MMBtu at a cost effectiveness of \$2,515/ton to \$3,163/ton in 2008 dollars,¹⁴⁷ or \$2,434/ton to \$3,060/ton in 2016 dollars. In its FIP for Utah, EPA found that the cost effectiveness of SCR controls plus low NO_x burners/overfire air was cost effective to require as BART at Hunter Units 1 and 2 and Huntington Units 1 and 2 at costs ranging from \$2,697/ton to \$2,928/ton in 2014 dollars, or \$2,606/ton to \$2,830/ton in 2016 dollars.¹⁴⁸

Thus, the costs of add-on SO₂ controls at White Bluff using either a dry FGD or DSI at 50-80% control are not outside the range of the costs that other similar sources have had to incur to meet BART, even with an enforceable shortened remaining useful life of the units. Further, there is precedent for requiring pollution controls to meet BART despite a source taking an enforceable limit on its remaining useful life. For example, the Boardman Power Plant in Oregon was a BART-subject EGU that was subject to an enforceable emission limit on the unit's remaining useful life to shut down or cease firing coal by December 31, 2020, and yet was still required to install pollution controls to meet BART despite the significantly shortened remaining useful life. Specifically, the Boardman Power Plant was required to install low NO_x burners and modified overfire air to meet NO_x BART and also DSI to meet SO₂ BART, along with its enforceable requirement to shut down by December 31, 2020.¹⁴⁹ The SO₂ control requirements were imposed with a required compliance date of July 2014, which gave the unit a remaining useful life for the cost effectiveness analyses of only 6.5 years from the BART compliance date to the date of required shut down or cessation of burning coal.¹⁵⁰ As stated above, Oregon DEQ found that the costs of DSI at Boardman were reasonable at \$3,370/ton, even with the enforceable commitment to cease firing coal by December 2020.¹⁵¹ Because the Boardman plant was not proposing to shut down or cease firing coal until after the BART compliance deadline (i.e., within 5 years of EPA's approval of the regional haze SIP pursuant to 40 C.F.R. 51.308(e)(1)(iv)), Oregon found that those controls that were cost effective would be required to meet BART in the interim until the plant shut down or ceased firing coal.¹⁵²

Similarly, the Centralia Power Plant in Washington state has two EGUs both of which were subject to BART. Despite being subject to an enforceable requirement to cease burning coal by December 31, 2020 at one unit and by December 31, 2025 at the other units, the state of Washington found that installation of selective non-catalytic reduction (SNCR) plus changing coal to a higher heat content coal and lower sulfur and nitrogen content coal (termed "Flex Fuel") was necessary to meet BART.¹⁵³ In addition, one of BART-subject Units 3 or 4 of the

¹⁴⁹ 2008 Oregon Regional Haze Plan, as revised December 9, 2010, at 155-6; as discussed in EPA's proposed approval of Oregon's Regional Haze Plan, 76 Fed. Reg. 12,651 at 12,660-662 (Mar. 8, 2011).

¹⁵⁰ 76 Fed. Reg. 12,662 (Mar. 8, 2011).

¹⁵¹ 76 Fed. Reg. 12,651 at 12,660-662 (Mar. 8, 2011).

¹⁵² Oregon considered as an option in its regional haze plan that, if Boardman shut down by 2015-/2016, no SO₂ BART controls would be required because Boardman would have shut down in lieu of installing SO₂ controls by the BART compliance deadline. See 2008 Oregon Regional Haze Plan, as revised December 9, 2010, at 154.

¹⁵³ See 77 Fed. Reg. 30,467 at 30,470-2 (May 23, 2012).

Northeastern Power Plant in Oklahoma was required to install DSI plus baghouses despite being subject to an enforceable limit to shut down by December 31, 2026, while the other unit was not required to install DSI and a baghouse but was required to shutdown much earlier by April 16, 2016.¹⁵⁴

D. Revisions to Entergy’s Cost Effectiveness and Visibility Improvement with Low Sulfur Coal Show Lower Costs and Lower Visibility Improvement than Projected by Entergy.

As discussed in Section I.B.1. above, Entergy applied a flawed approach to determining cost effectiveness of LSC. To compare costs of LSC to the add-on pollution controls for which revised cost effectiveness are presented herein, I have calculated revised cost effectiveness values for use of LSC at White Bluff Units 1 and 2. I assumed a baseline of 2001-2003 for the reasons provided in Section I.C. above, including to reflect an SO2 emission reduction from use of LSC since the annual average SO2 rate over the 2009-2013 baseline used by Entergy is lower than the 0.6 lb/MMBtu SO2 limit that Entergy has proposed with LSC. For the purpose of this analysis, I assume Entergy’s cost estimate of an additional \$0.50 per ton of coal for lower sulfur coal is an accurate cost projection, which Entergy claimed “was the premium provided to EAI’s fuel purchasing department by its coal suppliers.”¹⁵⁵ I converted this cost estimate to a \$ per MMBtu value by using Entergy’s claimed heating value of the coal of 8,587 Btu/lb which Entergy stated was based on 2009-2013 values¹⁵⁶ (which also reflects when the units were burning more lower sulfur coal, having an annual average SO2 rate of less than 0.6 lb/MMBtu as previously stated). Annual emission reductions were estimated based on the percent reduction from the 2001-2003 annual average SO2 emission rate at each unit to a 0.60 lb/MMBtu emission rate reflective of low sulfur coal. I also assumed the annual heat input would be the same as the 2001-2003 annual average heat input. The table below shows revised cost effectiveness values for LSC based on the methodology and inputs described above.

Table 6. Revised Cost Effectiveness for LSC Using 2001-2003 Baseline and Heat Input¹⁵⁷ and Entergy’s LSC Premium of \$0.50 per Ton

White Bluff Unit	Annual Costs of LSC	Annual SO2 Reductions, tpy	Cost Effectiveness of LSC, \$/ton
1	\$1,665,805	2,508	\$664
2	\$1,501,780	1,528	\$983

This revised analysis shows that the costs per ton for use of LSC are much lower per ton than Entergy’s calculation of cost effectiveness of LSC which was \$1,150/ton for White Bluff Unit 1 and \$1,148 /ton for White Bluff Unit 2.¹⁵⁸

¹⁵⁸ August 18, 2017 White Bluff BART Update at 4-5.

E. Entergy's Revised SO₂ Modeling Analysis for White Bluff Should Have Been Based on Baseline Emissions from 2001-2003.

Entergy submitted revised visibility modeling in its August 18, 2017 BART Update using baseline emissions based on 2009-2013 for all pollutants.¹⁵⁹ In its previous BART modeling which EPA relied on in issuing its FIP¹⁶⁰, Entergy relied on 2001-2003 emissions for baseline SO₂ emissions, but relied on more recent emissions from 2009-2011 for other pollutants primarily because NO_x emission rates had decreased due to installation of a neural net system and extensive boiler tuning completed in 2006.¹⁶¹ For the reasons discussed above regarding the cost effectiveness analyses, the baseline SO₂ emissions in Entergy's updated BART analysis should have been based on 2001-2003 emissions rather than on 2009-2013 emissions.

Specifically, use of a 2001-2003 baseline period is consistent with the baseline period that EPA has stated is to be used for baseline visibility conditions in EPA's regional haze rules. As EPA stated in its July 1, 1999 regional haze rulemaking:

After considering public comments on the baseline issue, EPA has determined that the most appropriate "baseline period" would be a fixed, 5-year period extending from calendar year 2000 through calendar year 2004. The EPA concluded that a standard baseline period provides for greater national consistency in establishing this important value, and therefore, is preferable to a provision allowing the baseline period to be a variable number of years. Using a common number of years and data points to calculate the baseline value for each site is consistent with fundamental statistical principles and will provide for easy comparison of data from multiple sites as the program is implemented.

64 Fed. Reg. 35728 (July 1, 1999).

Entergy has not provided any basis for deviating from the 2001-2003 baseline period for SO₂ emissions for its BART visibility modeling. The fact that Entergy has added low sulfur coal as a BART control option further necessitates the use of a 2001-2003 baseline for the cost effectiveness analysis because a review of the more recent 2009-2013 SO₂ emissions at White Bluff Units 1 and 2 shows that the units were emitting SO₂ at annual average rates below the assumed 0.60 lb/MMBtu LSC emission rate.¹⁶² However, for the purpose of this revised BART analysis, it is the only modeling available to show the visibility improvements expected with DSI and LSC, because Entergy's prior BART modeling which EPA relied on for its FIP only evaluate the visibility benefits from two controls – dry FGD and a wet FGD system at White Bluff Units 1 and 2.¹⁶³

¹⁶³ See 80 Fed. Reg. 18,972 (Apr. 8, 2015).

F. Entergy's Revised Modeling Analysis Overstated the Visibility Benefits of Low Sulfur Coal from Entergy's 2009-2013 Baseline.

To determine the visibility benefits of BART control options, one generally compared modeling of baseline emission rates and modeling of projected controlled emission rates for each BART option. Because visibility impacts are measured on a 24-hour basis, the highest emitting day mass emission rate is modeled for the baseline scenario, and a projected highest emitting day for the BART control is modeled which is based on the control efficiency of the BART control option applied to the baseline highest emitting day mass emission rate.¹⁶⁴ However, Entergy did not follow the approach outlined in EPA's BART Guidelines for determining the daily emission rate to model for low sulfur coal. In fact, Entergy's projection of the maximum hourly SO₂ rate for modeling LSC resulted in a much lower emissions rate than a properly calculated maximum hourly rate with LSC based on the 2009-2013 baseline used in Entergy's revised modeling.

Entergy assumes a 0.6 lb/MMBtu emission rate achievable with LSC.¹⁶⁵ Assuming that Entergy is proposing this emission limit as a 30-boiler operating day average¹⁶⁶, a comparison of the LSC emission limit with the maximum 30-boiler operating day average lb/MMBtu SO₂ rates at White Bluff Units 1 and 2 over Entergy's 2009-2013 baseline period shows that a 0.6 lb/MMBtu 30-boiler operating day average emission limit reflects an 8.68% reduction from the maximum 30-boiler operating day average SO₂ rate at each White Bluff unit over 2009-2013 of 0.657 lb/MMBtu.¹⁶⁷ Based on this, Entergy should have projected maximum daily pound per hour SO₂ emission rates for LSC modeling based on an 8.68% reduction from the maximum daily pound per hour SO₂ rates over Entergy's 2009-2013 baseline period for its modeling of each unit with LSC. Instead of following this method outlined in EPA's BART Guidelines, it appears that Entergy projected maximum daily emissions with LSC simply based on the maximum permitted heat input capacity of each White Bluff unit of 8950 MMBtu/hour multiplied by the proposed 0.6 lb/MMBtu LSC emission rate¹⁶⁸, which assumes the White Bluff units will not emit SO₂ at daily emission rates any higher than what the proposed BART limit would require on a 30-boiler operating day average basis. This greatly understates the maximum daily SO₂ emissions that could be allowed at White Bluff Units 1 and 2 and still enable the units to comply with a 30-boiler operating day average 0.6 lb/MMBtu emission limit with LSC. Table 7 below shows the pound per hour SO₂ rate that Entergy modeled for White Bluff Units 1 and 2 based on the methodology outlined in EPA's BART Guidelines compared to what should have been modeled based on a proper projection of emissions.

¹⁶⁴ See EPA's BART Guidelines at 40 C.F.R. Part 51, Appendix Y, Section IV.D.5.

¹⁶⁵ August 18, 2017 White Bluff BART Update at 1-2.

¹⁶⁶ Entergy's August 18, 2017 states that 0.6 lb/MMBtu can be met on a rolling 30 day average basis, although Entergy also compares the 0.6 lb/MMBtu rate with LSC to maximum 30-boiler operating date average SO₂ rates during the 2009-2013 baseline. See August 18, 2017 White Bluff BART Update at 1-2, 4-1 (fn 15), and 4-4.

¹⁶⁷ See Ex. 34, spreadsheet with White Bluff LSC Calculations at tabs "WB 1" and "WB 2," cell T10. Note Entergy calculates an 8.75% reduction based on a comparison to the maximum 30-boiler operating day SO₂ rate during the baseline period, but did not cite the maximum 30-boiler operating day average rate for each White Bluff unit during the baseline period. See August 18, 2017 White Bluff BART Update at 4-1, fn 15.

¹⁶⁸ That is, 8950 MMBtu/hour x 0.6 lb/MMBtu = 5,370.0 lb/hour.

Table 7. Comparison of Entergy’s Modeled SO2 Emission Rate for LSC Compared to the SO2 Emission Rate Reflective of 8.68% Reduction in Maximum Daily SO2 Baseline Emissions¹⁶⁹

White Bluff Unit	Entergy’s Baseline Modeled SO2 Rate, lb/hr	Entergy’s LSC Modeled SO2 Rate, lb/hr	Properly Projected LSC lb/hr SO2 rate based on 8.68% Reduction from Maximum Daily Baseline Emissions, lb/hr	Percent SO2 Reduction Assumed in Entergy’s LSC Modeling from Baseline
1	6,771.9	5,370.0	6,184.4	20.7%
2	6,622.3	5,370.0	6,047.7	18.9%

It must be noted that the percent reduction required by Entergy’s proposed low sulfur coal BART limit of 0.6 lb/MMBtu could be even less than 8.68%. That is because Entergy has a proposed a 0.6 lb/MMBtu limit¹⁷⁰ rather than a 0.60 lb/MMBtu limit, which means that SO2 emission rates as high as 0.64 lb/MMBtu could be rounded down to 0.6 lb/MMBtu and still show compliance with Entergy’s proposed SO2 limit. An emission rate of 0.64 lb/MMBtu would only require a 2% reduction in the maximum 30-boiler operating day SO2 rate of the 2009-2013 period of 0.657 lb/MMBtu, and thus maximum projected daily emissions with LSC could be only 2% lower than the 2009-2013 baseline pound per hour rates. Regardless, for the purpose of this revised projection of maximum daily SO2 rates with LSC, I assume that the White Bluff units would comply with a 0.60 lb/MMBtu 30-boiler operating day average SO2 limit with the use of low sulfur coal.

In its revised modeling included in its August 18, 2017 White Bluff BART Update, Entergy submitted the results of its modeling analysis that included LSC as a BART control option from a 2009-2013 baseline.¹⁷¹ Based on the changes in Entergy’s modeled hourly SO2 emission rates (shown in the second and third columns of Table 7 above), Entergy found that LSC at each White Bluff unit would provide visibility improvements from Entergy’s 2009-2013 baseline of ranging from 0.097 dv to 0.143 dv per unit.¹⁷² However, as shown in Table 7 above, Entergy did not properly project maximum daily pound per hour SO2 rates with LSC and greatly understated the maximum daily pound per hour SO2 rates that could occur with LSC, which means the visibility benefits of LSC were overstated in Entergy’s revised modeling analysis. Since each unit was modeled by itself, one can scale Entergy’s modeled visibility improvement with LSC to adjust Entergy’s projected visibility benefit with LSC to reflect the revised maximum daily emission rate show in Table 7 above by multiplying Entergy’s modeled delta deciview improvement with LSC by the ratio of the reduction from baseline emissions using the more properly projected maximum daily emission rate to Entergy’s projected reduction in maximum daily emission rates with LSC. The results of this scaling of Entergy’s modeled visibility benefits with LSC are shown in Table 8 below.

¹⁶⁹ See Ex. 34, spreadsheet with White Bluff LSC Calculations, at tabs “WB 1” and “WB 2,” cell T13.

¹⁷⁰ See August 18, 2017 White Bluff BART Update at 1-2.

¹⁷¹ *Id.* at 3-2, 4-7 to 4-8

¹⁷² *Id.* at 4-7 to 4-8.

Table 8. Adjusted Visibility Improvement over Baseline with LSC at White Bluff Units 1 and 2 Based on Entergy’s Modeling¹⁷³ and Updated Projections¹⁷⁴ of Maximum Daily lb/hr SO2 Rate with LSC.¹⁷⁵

White Bluff Unit	Entergy’s Projected Change in Max Daily SO2 Rate with LSC, lb/hr	Revised Projected Change in Max Daily SO2 Rate with LSC, lb/hr	Ratio of Revised Change in Max Daily SO2 Rate to Entergy’s Projected Change in Max Daily SO2 Rate	Scaled Visibility Improvement over Baseline, Δ dv			
				CACR	UPBU	HERC	MING
1	1,409.1	594.7	0.422	0.054	0.060	0.070	0.049
2	1,252.3	574.6	0.459	0.045	0.058	0.063	0.056

Based on this scaling analysis and the projection that the White Bluff units can emit at a maximum daily SO2 rate much higher than projected by Entergy and still comply with the 0.6 lb/MMBtu 30-boiler operating day average limit, it appears that Entergy greatly overstated the visibility benefits with low sulfur coal compared to visibility impacts using a 2009-2013 baseline.

G. Summary of Revised Cost Effectiveness Analysis Presented Herein and Projected Visibility Benefits with the BART Controls Evaluated for White Bluff Units 1 and 2 Assuming ADEQ Adopts an Enforceable Limit Requiring Cessation of Coal Burning at White Bluff by December 31, 2028.

The following presents a summary of the revised cost effectiveness analyses presented in this report assuming that ADEQ adopts an enforceable requirement that Entergy cease firing coal in White Bluff Units 1 and 2 by December 31, 2028, which is the date Entergy has most recently stated it is willing to commit to for a cessation of coal-firing at White Bluff.¹⁷⁶ Assuming, consistent with the current FIP, that compliance with a BART limit reflective of dry FGD continues to be required no later than October 27, 2021 (as required by 40 C.F.R. §52.173(c)(7)) and assuming that, consistent with Entergy’s revised BART analysis, installation of DSI would be done two years earlier in 2019¹⁷⁷, the cost effectiveness analysis for dry FGD should be based on a 7.17 year life and the cost effectiveness for DSI should be based on a 9.17 year life given that Entergy’s consultant has indicated DSI can be implemented two years earlier than dry FGD.¹⁷⁸ Table 9 below summarizes the cost effectiveness values calculated in this report for dry FGD and a 7.17 year life, DSI (including DSI plus a baghouse) for a 9.17 year life, and low

	Enhanced DSI (with BH at 80%)	\$3,473	0.460	0.531	0.429	0.435
	DSI (at 50%)	\$2,673	0.274	0.359	0.303	0.333
	LSC	\$983	0.045	0.058	0.063	0.056

As discussed previously in this report, all of the add-on SO2 BART controls evaluated, even with a shortened remaining useful life, are cost effective in that the costs of control are not outside the range that other similar sources have had to incur to meet BART, with only SDA at White Bluff Unit 2 being on the higher end of the range of costs that EPA and states have required to meet BART. If ADEQ ultimately adopts an enforceable requirement for the White Bluff units to cease firing coal by December 31, 2030 as currently listed in ADEQ’s draft Administrative Order, dry FGD will be even more cost effective as shown in Table 2 at a cost effectiveness of \$3,244 to \$3,770 per ton. Dry FGD is also the most effective SO2 BART option in terms of ensuring the greatest SO2 emission reductions and the most visibility improvement. Yet, ADEQ has only proposed the use of low sulfur coal to meet BART at the White Bluff units

¹⁷⁹ See Table 3 above for dry FGD cost effectiveness, Table 2 above for DSI cost effectiveness with baghouse at 80% control and at 50% control, and Table 6 for LSC cost effectiveness.

¹⁸⁰ *Id.* at 4-7 to 4-7. Note that SDA in Entergy’s modeling results refers to a spray dryer absorber, which is the same as a dry FGD system.

¹⁸¹ See August 18, 2017 White Bluff BART Update at 4-7 to 4-8.

with a shortened remaining useful life (which ADEQ has not even proposed as a clearly enforceable limit on the life of the units). Based on the analyses summarized in the above table, even assuming ADEQ adopts an enforceable deadline to cease firing coal by December 31, 2028 at the White Bluff units, LSC alone does not satisfy BART. At the very minimum, DSI should be considered as BART if ADEQ adopts an enforceable limit requiring White Bluff Units 1 and 2 to cease firing coal by December 31, 2028, because DSI can be readily implemented, it is cost effective, and it would result in significant visibility improvement at four Class I areas.

ADEQ's proposed BART determination for the White Bluff units is inconsistent with its BART finding at Flint Creek. Specifically, ADEQ indicates the installation of a NID™ dry scrubber at Flint Creek to meet an SO₂ limit of 0.06 lb/MMBtu, at a cost effectiveness of \$3,845 per ton and an expected visibility improvement of up to 0.647 dv, is justified to meet SO₂ BART.¹⁸² Yet, a dry FGD at White Bluff Unit 1 and Enhanced DSI (with a baghouse at 80% control) at White Bluff Unit 2 have similar or lower costs on a dollar per ton basis compared to the SO₂ BART requirement for Flint Creek, and would achieve similar visibility benefits as ADEQ's proposed SO₂ BART finding for Flint Creek. It is not clear how ADEQ can justify requiring a NID™ scrubber at Flint Creek and yet not require any add-on SO₂ controls at White Bluff, even if ADEQ adopts an enforceable restriction on the remaining useful life of coal-firing at the White Bluff units. If ADEQ does not adopt a clearly enforceable deadline for the White Bluff units to cease firing coal by December 31, 2028, then installation of a dry FGD system at each unit is warranted to meet BART consistent with EPA's FIP requirements promulgated on September 27, 2016 (81 Fed. Reg. 66,332-66,421). Even if ADEQ adopts an enforceable requirement for the units to cease firing coal by December 31, 2030, the cost effectiveness of dry FGD systems assuming a 9.17 year life as shown in Table 2 above is less than the \$3,845/ton cost effectiveness of SO₂ controls to meet BART at Flint Creek. Further, the visibility improvements expected with a dry FGD system at just one White Bluff unit is similar to the visibility improvement expected with SO₂ BART at Flint Creek.¹⁸³

¹⁸² October 2017 Public Review Draft at 26-27.

¹⁸³ ADEQ indicates the operating of a NID™ dry scrubber at Flint Creek is expected to result in up to a 0.647 dv improvement to existing visibility impairment. October 2017 Public Review Draft at 26. Entergy's 2013 modeling based on a 2001-2003 baseline predicted visibility improvements with dry FGD at each White Bluff units ranging from 0.593 to 0.813 dvs. 80 Fed. Reg. 18,972 (Apr. 8, 2015). Even using a more recent baseline of 2009-2013, Entergy's revised modeling shows that dry FGD systems at each White Bluff unit would result in visibility improvements ranging from 0.486 to 0.642 dv as shown in Table 9 above. See December 18, 2017 White Bluff BART Update at 4-7 to 4-8.

II. Evaluation of ADEQ’s Proposed Sulfur Dioxide Reasonable Progress Determination for Independence Units 1 and 2.

On September 27, 2016, EPA finalized a regional haze Federal Implementation Plan (FIP) to address those portions of the Arkansas Regional Haze SIP that EPA disapproved on March 12, 2012.¹⁸⁴ In the FIP, EPA required sulfur dioxide (SO₂) emission limits at Independence Units 1 and 2 of 0.06 lb/MMBtu on a 30-boiler operating day average basis, based on installation of a dry flue gas desulfurization system (dry FGD) or other technology that achieves that same level of control.¹⁸⁵ Compliance is required no later than 5 years from the effective date of EPA’s rule, or by October 27, 2021.¹⁸⁶ On April 25, 2017, in response to a petition for reconsideration submitted to EPA by ADEQ and other parties, EPA issued a partial administrative stay for 90 days of that FIP.¹⁸⁷ Among other things, EPA granted reconsideration of the compliance dates for the SO₂ emission limits for Independence Units 1 and 2.¹⁸⁸ However, there has been no stay of the FIP requirements. Entergy is still required to meet an SO₂ limit of 0.06 lb/MMBtu on a 30-boiler operating day average basis at the Independence Units 1 and 2 by October 27, 2021.¹⁸⁹

ADEQ has proposed a SIP revision that would replace the SO₂ requirements of the FIP with a 0.6 lb/MMBtu limit on a 30-boiler operating day average basis within three years of ADEQ’s adoption of its proposed Administrative Order, based on the use of low sulfur coal at Independence Units 1 and 2.¹⁹⁰

On December 18, 2017, ADEQ issued a Notice of Data Availability to make publicly available information previously submitted by Entergy to ADEQ which Entergy had claimed to be a Trade Secret.¹⁹¹ Included in the information made publicly available by ADEQ is a September 27, 2017 Entergy submittal analyzing reasonable progress for the first planning period.¹⁹² ADEQ claims that it did not rely on this submittal for its proposed SIP.¹⁹³ Regardless, ADEQ provided notice of this additional information from Entergy “due to its potential relevance to the public as they develop comments on the Proposed SIP.”¹⁹⁴

ADEQ focused on the following three control options for its evaluation of reasonable progress measures at Independence Units 1 and 2: (1) wet FGD, (2) dry FGD, and (3) low sulfur coal. For dry FGD systems, it appears that ADEQ is relying on cost effectiveness analyses prepared by EPA and by Entergy.¹⁹⁵ For low sulfur coal, ADEQ relies on cost data provided by

Entergy for the cost per ton of low sulfur coal at the White Bluff plant, and ADEQ provides its own cost effectiveness analyses.¹⁹⁶

In Entergy's September 27, 2017 Reasonable Progress Analysis made available in ADEQ's December 18, 2017 Notice of Data Availability, Entergy proposes to cease firing coal at the Independence Units 1 and 2 by the end of 2030.¹⁹⁷ Entergy provided revisions to EPA's cost effectiveness analyses conducted for its FIP to reflect a 9 year remaining useful life, and determined the costs for compliance with the SO₂ limits of the EPA FIP would be approximately \$4,000/ton using EPA's cost estimates and a 9 year life.¹⁹⁸ It must be noted that Entergy's revised cost effectiveness for dry scrubbers based on a 9 year life shows that the cost of controls are still reasonable, because other similar sources have had to incur similar costs of control to meet reasonable progress requirements as discussed in Section I.C. of this report. However, notably, Entergy's September 27, 2017 submittal does not clearly state that Entergy is willing to take an enforceable restriction on the remaining useful life of Independence Units 1 or 2, which contrasts with Entergy's August 18, 2017 White Bluff BART Update in which Entergy states it is willing to take enforceable requirements to cease firing coal at White Bluff Units 1 and 2 by December 31, 2028.¹⁹⁹ Similarly, ADEQ's October 2017 proposed SIP revision states that "there are no State or federally enforceable limitations on continued operations at Entergy Independence" and thus assumes a 30-year amortization period.²⁰⁰ ADEQ's October 2017 proposed SIP revision also does not include any draft Administrative Order requirements pertaining to the cessation of burning coal or otherwise shutting down at Independence Units 1 or 2. However, ADEQ does state that "[m]arket trends for coal and natural gas have resulted in decreased dispatch of Entergy Independence," and ADEQ cited to the Energy Information Administration in stating that "the economic pressure on coal units due to low natural gas prices is expected to continue" through 2018 and beyond.²⁰¹ ADEQ also states in its finding that low sulfur coal is sufficient to achieve reasonable progress that "the significant capital investment costs of Dry FGD would lock Entergy into continued operation of the aging Entergy Independence for thirty years in order to avoid stranded costs associated with the installation of the Dry FGD."²⁰² Thus, it appears ADEQ may be taking into account a shortened remaining useful life of the Independence units into account in its proposed SIP revision, at least to some extent. However, given that ADEQ has not proposed any enforceable limitation on the remaining useful life of the Independence units, I did not evaluate any such limitation for the Independence units in a revised cost analysis.

Below I provide comments on ADEQ's proposed SO₂ reasonable progress determination for the Independence Units 1 and 2.

²⁰¹ *Id.* at 43.

²⁰² *Id.* at 47.

A. Dry FGD Systems at Independence Units 1 and 2 Are Cost Effective As Reasonable Progress Measures.

ADEQ appears to claim that EPA's estimates of cost effectiveness for dry FGD at Independence Units 1 and 2 of \$2,853 per ton SO₂ reduced at Unit 1 and of \$2,634 per ton of SO₂ reduced²⁰³ were not reasonable costs of control, because ADEQ claims the costs exceed "screening thresholds used for cost-effectiveness in other approved reasonable progress analyses."²⁰⁴ For this claim, ADEQ cites to EPA's proposed rulemaking in the Kentucky regional haze SIP, claiming "EPA approved [reasonable progress goals] in Kentucky based on [the Clean Air Interstate Rule or CAIR] which had a \$2,000/ton SO₂ cost effectiveness screening threshold."²⁰⁵ However, in its proposed approval of the Kentucky regional haze plan, EPA states that the \$2,000 per ton of SO₂ controlled threshold was used "[f]or the limited purpose of evaluating the cost of compliance for the reasonable progress assessment in this first regional haze SIP for the *non-EGUs*...."²⁰⁶

In any event, there are numerous examples of states and EPA requiring controls to meet reasonable progress toward the national visibility goal at costs greater than \$2,000 per ton. For example, EPA approved installation of a dry FGD at the Colorado Springs Nixon Unit 1 as a reasonable progress measure at a cost effective of \$3,744/ton.²⁰⁷ In addition, EPA proposed a FIP of reasonable progress measures based on switching to a lower sulfur fuel oil at the fuel oil-fired boilers at the Kanoelehua Hill Power Plant, the Puna Power Plant, and the Shipman Power Plant at a cost effectiveness of approximately \$5,600/ton.²⁰⁸ EPA also approved Wyoming's adoption of reasonable progress requirements for each of the Jim Bridger units to install SCR at a cost effectiveness ranging from \$2,743/ton to \$3,403/ton in 2013 dollars, or \$2,619/ton to \$3,249/ton in 2016 dollars.²⁰⁹ In Texas, EPA required numerous scrubber retrofits at coal-fired power plants to meet reasonable progress requirements at costs up to \$3,221 per ton.²¹⁰ Further, these costs are within the range of cost effectiveness for controls EPA has required at EGUs to meet BART, as discussed at length in Section I.C. of this report. I incorporate those examples by reference here into the discussion of costs of dry FGD at Independence Units 1 and 2.

In the August 5, 2015 Technical Support Document of Conservation Organizations submitted to EPA in comments on its proposed FIP, I provided cost analyses for dry FGD systems at Independence Units 1 and 2 using the Sargent & Lundy IPM cost modules discussed in Section I above that also showed these controls were very reasonable at \$2,916/ton to \$2,772/ton (2012 \$) at Independence Units 1 and 2 respectively, which were based on 2012-2014 baseline and a 30-year life of controls.²¹¹ These costs would be \$2,702/ton and \$2,569/ton in 2016\$, based on changes in the CECPI index from 2012 to 2016.²¹² These cost numbers are

²⁰³ See 81 Fed. Reg. 66,352 (Sept. 27, 2016).

²¹² *I.e.*, multiplied by (541.7/584.6).

somewhat higher than EPA’s estimates, because I used a more recent baseline emissions period of 2012-2014 to reflect the higher sulfur coal being used during that timeframe.²¹³ I incorporate by reference and attach my August 5, 2015 report and relevant exhibits into these comments on ADEQ’s proposed regional haze SIP rulemaking.²¹⁴

ADEQ stated that there has been decreased dispatch of the Independence units due to low natural gas prices.²¹⁵ To address ADEQ’s statements that the Independence units have been and may be continued to be dispatched less frequently, I conducted an additional cost effectiveness analyses using the Sargent & Lundy dry FGD IPM cost module discussed in Section I.C. of this report, using the most recent three years of 2014-2016 as baseline emission to reflect the current level of operation of the Independence units. The Independence units operated at approximately a 52-54% capacity factor on average over 2014-2016.²¹⁶ Because ADEQ has not proposed an enforceable limit on the remaining useful life of the coal-fired units, I assumed a remaining useful life of 30 years. With the exception of the timeframe for SO2 and operational baseline data and converting to 2016 dollars, all other parameters were held the same as assumed in my 2015 cost analysis. The results are shown in Table 10 below.

Table 10. Cost Effectiveness of Dry FGD Systems at Independence Units 1 and 2 based on a 2014-2016 Baseline and a 30 Year Life of Controls.²¹⁷

Independence Unit	Annualized Cost of Controls (2016 \$)	SO2 Reduced, tpy	Cost Effectiveness, \$/ton (2016 \$)
1	\$32,503,040	10,005	\$3,249
2	\$33,242,064	10,118	\$3,285

Thus, even if the Independence units are operated at lower capacity factors in the future, dry FGDs are still cost effective compared to previous reasonable progress determinations finalized by other states or EPA.

ADEQ’s October 2017 draft rulemaking also cites to Entergy’s revised cost effectiveness analysis for the Independence units submitted to EPA in August of 2015.²¹⁸ Specifically, Entergy’s cost effectiveness estimates for dry FGD at Independence Units 1 and 2 are based on a 2015 cost estimate for dry FGD at White Bluff Units 1 and 2, provided in Exhibit B of Entergy’s August 7, 2015 comments to EPA, which Entergy used to determine cost effectiveness of dry

²¹³ *Id.* at 61.

FGD at Independence Units 1 and 2.²¹⁹ According to ADEQ, Entergy calculated cost effectiveness of dry FGD at Independence Units 1 and 2 to be \$4,234/ton at Unit 1 and \$3,909/ton at Unit 2.²²⁰ It must first be noted that these costs are still within the range that other similar sources have had to incur to meet reasonable progress requirements, as discussed above and in Section I.C. of this report. However, as EPA stated in its September 2016 final FIP for Arkansas Regional Haze, Entergy's 2015 revised cost analyses relies on updated 2013 pricing from Alstom which Entergy did not attach to its August 2015 comments, and, therefore, EPA found Entergy's 2015 cost update to be undocumented.²²¹ Further, Entergy's 2015 cost numbers do not appear to comport with EPA's Control Cost Manual and are also based on an unrealistically high uncontrolled SO₂ rate for the coal used at Independence Units 1 and 2.

Specifically, a review of that 2015 Sargent & Lundy Cost Estimate for White Bluff Dry FGD shows that it includes costs that are not consistent with the overnight costing method of EPA's Control Cost Manual, including "Interest During Construction" (also known as AFUDC), owner's costs, and escalation of costs during construction.²²² Section I.B.4. of these comments explains how the methodology of the Control Cost Manual is based on the overnight costing methodology, and demonstrates that Entergy's cost analysis is not consistent with that methodology. I incorporate that section of my above comments by reference here with respect to Entergy's 2015 White Bluff cost analyses. EPA also raised the same issues with Entergy's 2015 cost analysis in its response to comments on its September 2016 final Arkansas Regional Haze FIP.²²³

Entergy's 2015 cost analysis also based the capital cost of the FGD equipment on an uncontrolled SO₂ rate of 1.2 lb/MMBtu, but the Independence units emit at half of that rate or lower.²²⁴ Assuming such a high uncontrolled SO₂ rate for the design and cost determination of the dry FGD systems overestimates the control costs associated with dry FGD. Instead, the control costs should have been based on the coal sulfur content that is currently used at the Independence units.

Thus, Entergy's 2015 cost estimates do not comport with the EPA's Control Cost Manual, and are improperly inflated. Because of the lack of conformance with EPA's Control Cost Manual and because the costs are not properly documented, ADEQ must not rely on Entergy's 2015 revised cost estimates.

²¹⁹ See Entergy's August 7, 2015 comments on EPA's Proposed Regional Haze FIP at 44, in October 2017 Public Review Draft at pdf page 1284, and Exhibit B to those comments, in October 2017 Public Review Draft beginning at pdf page 1326.

²²⁴ *Id.* at 10, 24-26 (in October 2017 Public Review Draft at pdf pages 1339, 1353-55). See also October 2017 Public Review Package at 43, indicating that the Independence Units 1 and 2 emit SO₂ on a 30-boiler operating day average basis in the range of 0.48-0.63 lb/MMBtu.

In summary, assuming no enforceable limitations are imposed on the remaining useful life of the Independence units, dry FGD systems are cost effective for the Independence units and are consistent with costs that other similar sources have had to bear to meet regional haze requirements. Further, ADEQ is not justified in applying a \$2,000/ton screening threshold in determining reasonableness of costs for reasonable progress measures.

B. ADEQ's Cost Effectiveness Determination of Low Sulfur Coal is Flawed.

In its reasonable progress control evaluation for Independence Units 1 and 2, ADEQ estimates costs for low sulfur coal by assuming the same low sulfur cost premium for low sulfur coal that Entergy provided for White Bluff of \$0.50/ton and multiplying that by annual fuel consumption data reported to the Energy Information Administration in Form EIA-923 for 2009-2013.²²⁵ ADEQ calculated an average cost effectiveness for low sulfur coal of \$2,284/ton at Independence Unit 1 and \$2,173/ton at Independence Unit 2, which ADEQ determined were reasonable costs of control. Notably, these costs are virtually identical to the cost effectiveness of dry FGD at each unit.²²⁶ ADEQ's analysis is flawed for several reasons.

First, ADEQ's cost effectiveness analysis is based on the incorrect assumption that the Independence units have actual annual SO₂ emission rates that exceed ADEQ's proposed low sulfur coal limit of 0.6 lb/MMBtu. A review of the annual average SO₂ emission rates at each Independence unit, calculated from actual tons of SO₂ and MMBtu heat input per year reported to EPA's Clean Air Markets Database, shows that neither unit has an annual average SO₂ emission rate that exceeds 0.6 lb/MMBtu. Because cost effectiveness of a pollution control is based on annual average emission reductions, and because actual annual average SO₂ rates are lower than 0.6 lb/MMBtu at both Independence Units 1 and 2 (and have been for at least the last 16 years), *no* annual SO₂ emissions reductions will be realized with ADEQ's low sulfur coal control. Thus, the cost effectiveness of low sulfur coal must be considered to be zero. Table 11 below shows the actual SO₂ emission rates and Independence Unit 1 and 2 and shows that the annual average SO₂ emission rate has actually been increasing over time.

²²⁵ October 2017 Public Review Package at 44. *See also* ADEQ spreadsheet "independence-lsc-costs.xlsx."

²²⁶ *Id.* at 43-44, and 47.

Table 11. Annual Average SO2 Emission Rates at Independence Units 1 and 2, 2001-2016²²⁷

Year	Independence Unit 1 Annual Average SO2, lb/MMBtu	Independence Unit 2 Annual Average SO2, lb/MMBtu
2001	0.36	0.36
2002	0.41	0.42
2003	0.37	0.38
2004	0.39	0.40
2005	0.39	0.40
2006	0.42	0.44
2007	0.44	0.44
2008	0.45	0.44
2009	0.46	0.47
2010	0.47	0.47
2011	0.54	0.54
2012	0.59	0.59
2013	0.55	0.55
2014	0.56	0.54
2015	0.57	0.55
2016	0.57	0.58

Thus, ADEQ’s proposed low sulfur coal limit of 0.6 lb/MMBtu should not be viewed as a limitation or control measures necessary to *achieve reasonable progress* towards natural visibility, but rather as a perpetuation of the status quo emissions at Independence Units 1 and 2.

Second, it must be noted that ADEQ’s proposed 0.6 lb/MMBtu SO2 limit does not even require much if any reduction in SO2 emissions on a 30-boiler operating day average basis as ADEQ’s proposed limit would apply. A review of the Independence units’ 30-boiler operating day average SO2 rates shows that the maximum 30-boiler operating day average SO2 rates over 2009-2016 at Independence Units 1 and 2 were 0.63 lb/MMBtu at Unit 1 and 0.61 lb/MMBtu at Unit 2.²²⁸ Given that ADEQ appears to be proposing a 0.6 lb/MMBtu 30-boiler operating day average limit²²⁹, these actual 30-boiler operating day averages could be rounded to the nearest one-tenth lb/MMBtu rate and thus still show compliance with a 0.6 lb/MMBtu.

There are other problems with ADEQ’s cost effectiveness analysis as well. For calculating the tons per year removed, ADEQ used EPA’s baseline emissions from its cost effectiveness analysis of dry FGD for its 2016 FIP, which was in turn based on the annual average SO2 emissions over 2009 to 2013 minus the maximum and minimum year. A review of the annual emissions data shows that EPA excluded years 2009 (minimum year) and 2012

²²⁷ See Ex. 35, Spreadsheet with Annual Independence Emissions, 2001 to 2016.

²²⁸ See Spreadsheet with Actual 30-Boiler Operating Day Average SO2 Rates at Independence, 2009 to 2016. Ex. 36, at tabs “Ind 1” and “Ind 2,” cell T7.

²²⁹ ADEQ’s draft Administrative Order confusingly lists the SO2 emission limit for Units 1 and 2 as follows: “0.6 pounds of sulfur dioxide per million British thermal units (0.60 lb/MMBtu)....” In the discussion of the reasonable progress requirement, ADEQ only refers to a 0.6 lb/MMBtu emission limit. October 2017 Public Review Draft at 47, and Draft Administrative Order at 4 (pdf page 1777). It appears that ADEQ is intending to impose a 0.6 lb/MMBtu limit rather than a 0.60 lb/MMBtu limit.

(maximum year) from its annual average SO₂ baseline emission calculation for Unit 1, and EPA excluded 2010 (minimum year) and 2012 (maximum year) from its annual average SO₂ baseline emission calculation for Unit 2.²³⁰ Importantly, for the years incorporated into EPA’s baseline emissions, the 30-boiler operating day average SO₂ rates at each Independence unit were at or below 0.60 lb/MMBtu. This is demonstrated in Table 12 below. Thus, the requirement to use low sulfur coal to achieve a 0.6 lb/MMBtu 30-boiler operating day average limit would not have required any changes in coal and would not result in any SO₂ reductions from those baseline emissions. Yet, in its low sulfur coal cost effectiveness analysis, ADEQ assumed SO₂ emissions reduction based on a 4.66% reduction from EPA’s baseline emissions and assuming a \$0.50 per ton premium for use of low sulfur coal that would not be necessary to comply with ADEQ’s proposed 0.6 lb/MMBtu SO₂ limit based on the baseline used in EPA’s cost analysis.

Table 12. Maximum 30-Boiler Operating Day Average lb/MMBtu SO₂ Emissions Rate at Independence Units 1 and 2, Based on Emissions and Heat Input Data Reported to EPA’s Air Markets Program Database, for 2009-2013.²³¹

Year	Independence Unit 1, Maximum 30-Boiler Operating Day SO ₂ Rate, lb/MMBtu	Independence Unit 2, Maximum 30-Boiler Operating Day SO ₂ Rate, lb/MMBtu
2009	0.49	0.49
2010	0.52	0.51
2011	0.58	0.57
2012	0.63	0.62
2013	0.60	0.60

ADEQ also claimed to use tons of coal used at each unit (as reported to the Energy Information Administration) for years 2009-2013 excluding the maximum and minimum year, but a review of ADEQ’s spreadsheet shows that ADEQ used the period of 2009 to 2016 and excluded the maximum and minimum years.²³² It is not clear why ADEQ used a longer period of data on tons of fuel burned at each unit compared to the 2009-2013 period used for baseline emissions.

In summary, ADEQ’s cost effectiveness calculations for low sulfur coal at Independence Units 1 and 2 are flawed. ADEQ’s proposed low sulfur coal requirement and 0.6 lb/MMBtu emission limit should be considered not as a control scheme that would reduce current emissions but instead be viewed as a perpetuation of the status quo emissions from the Independence units. Accordingly, the cost effectiveness of such controls is zero, because the Independence units are already complying with this requirement on an annual basis, as shown in Tables 11 and 12 above.

²³⁰ Based on a review of the actual annual emissions data for 2009 – 2013 in the spreadsheet “independence-sda-costs.xlsx” in ADEQ’s files for its October 2017 rulemaking, at tab “Annual Emissions.”

²³¹ See Spreadsheet with Actual 30-Boiler Operating Day Average SO₂ Rates at Independence, 2009 to 2016. Ex. 36, at tabs “Ind 1” and “Ind 2,” cells T13, T16, T19, T22, and T25..

²³² Based on a review of ADEQ spreadsheet “independence-lsc-costs.xlsx,” at “Calcs” tab, cells G9 and G10.

C. Summary: Dry FGD Systems at Independence Units 1 and 2 Are Cost Effective Controls to Meet Reasonable Progress.

ADEQ's proposed regional haze revision has not provided any information to show that dry FGD systems are not cost effective controls at Independence Units 1 and 2. Although Entergy has indicated the Independence units will cease firing coal by 2030²³³, Entergy did not indicate a willingness to take an enforceable requirement to this effect, nor did ADEQ propose any limitation on coal-firing at the Independence units. Indeed, ADEQ's October 2017 proposed SIP revision states that "there are no State or federally enforceable limitations on continued operations at Entergy Independence" and thus assumes a 30-year amortization period.²³⁴ Based on these facts, it would not be appropriate to consider any limitations on coal firing at the Independence units in determining whether the costs of controls are reasonable. As shown in EPA's September 2016 FIP as well as my August 2015 Technical Support Document to the Conservation Organizations' comments on EPA's proposed FIP, the costs of dry FGD at Independence Units 1 and 2 are reasonable to justify such controls to meet reasonable progress.²³⁵ Even considering more recent levels of operation at the Independence units, which have been operating at lower capacity factors in recent years, dry FGD systems at the Independence units are still cost effective and will achieve significant SO₂ emission reductions from current emissions as shown in Table 10 above. ADEQ's proposed low sulfur coal control will not achieve any SO₂ emission reductions at the Independence units and thus will not achieve any additional progress towards the national visibility goal.

Curriculum Vitae

Victoria R. Stamper
P.O. Box 9571
Boise, Idaho 83707
stamper.vr@gmail.com

Areas of Expertise

Comprehensive knowledge of the Clean Air Act - accomplished in the requirements for new source review (NSR) and prevention of significant deterioration (PSD) construction permits, Title V operating permits, Maximum Achievable Control Technology (MACT) Approvals, Class I area protection including regional haze plans and best available retrofit technology (BART) determinations, and state implementation plans for compliance with the national ambient air quality standards.

Extensive experience with the air pollution issues related to coal-fired power plants – have evaluated numerous PSD permit applications, best available control technology determinations, and best available retrofit technology determinations for the fossil fuel-fired electric utility industry.

Professional Experience

Air Quality Consultant
Boise, ID 83707

April 2003 to
Present

I provide consulting services on numerous air quality issues such as:

- Reviewing/preparing comments on all aspects of air quality construction and operating permit applications and permits for industrial sources including coal-fired power plants.
- Providing technical expertise for the appeal of air quality permits that do not comply with federal or state clean air requirements.
- Investigating facility compliance with federal and state air quality regulations.
- Analyzing proposed or available mercury and other hazardous air pollutant controls for coal-fired power plants.
- Reviewing and commenting on Class I regional haze and visibility protection plans.
- Evaluating proposed best available retrofit technology determinations.
- Critiquing prevention of significant deterioration increment analyses.
- Evaluating and commenting on air quality analyses and environmental impact statements for proposed oil and gas development in the West.

Environmental Engineer/Legal Assistant
Reed Zars, Attorney at Law
Laramie, WY82070

May 2001 to
April 2003

Responsibilities included:

- Investigating industrial facilities' compliance with Clean Air Act requirements through review of public documents.
- Researching pollution reduction measures and effectiveness.
- Reviewing and preparing comments on proposed air quality construction and operating permits.
- Reviewing and preparing written comments on proposed EPA state implementation plan approvals regarding topics such as opacity regulations, emission limit exemptions, Class I area visibility plans and permitting regulations.

New Source Review Program Manager
Air and Radiation Program
U.S. Environmental Protection Agency, Region VIII
Denver, Colorado80202

December 1990
to April 2001

Responsibilities included:

- Serving as the Region VIII lead for state rules regarding the new source review and prevention of significant deterioration programs, and industrial source control measures.
- Reviewing all aspects of prevention of significant deterioration increment analyses.
- Reviewing state implementation plans for consistency with requirements of Clean Air Act.
- Preparing documents to justify EPA approval or disapproval of state submittals.
- Educating and assisting tribes in developing regulations for tribal implementation plans.
- Participating in workgroups to ensure national consistency and provide input on rulemakings.
- Reviewing state operating permit programs under Title V of the Clean Air Act.
- Researching and compiling the EPA-approved state implementation plans.
- Developing and reviewing state implementation plans for particulate matter nonattainment areas, as well as assisting in the preparation of requests to redesignate to attainment.
- Reviewing environmental impact statements for consistency with Clean Air Act.
- Serving as primary contact for air quality issues in the state of Wyoming.

Environmental Engineer
Envirometrics, Inc.
Seattle, Washington 98103

August 1989-
July 1990

Responsibilities included:

- Designing components of research projects pertaining to pollution control systems.
- Developing testing criteria and measuring the effectiveness of these control systems.
- Preparing air pollution permit applications and related documentation for industrial sources.
- Compiling input data for modeling of ambient air quality impacts on Class I areas.
- Developing emission inventories.

Selected Reports and Papers
