

Arkansas Department of Environmental Quality

Public Notice

The Arkansas Department of Environmental Quality (ADEQ) is publishing this Public Notice to provide interested persons the opportunity to comment on ADEQ's proposed state implementation plan (SIP) revision.

In this SIP proposal, Arkansas has included revisions to address disapproved portions of the Arkansas Regional Haze State Implementation Plan (AR RH SIP), submitted to EPA in 2008 and to replace emission limits for Arkansas subject-to-BART power plants and Entergy Independence included in the 2016 rule "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule" (AR RH FIP). This SIP revises Arkansas's reasonable progress goals and Arkansas's long-term strategy for the first Regional Haze planning period ending in 2018.

ADEQ will hold a public hearing on Tuesday, January 2, 2017 to receive public comments on the SIP revision. The public hearing will begin at 2:00 p.m. in the Commission Room at the Arkansas Department of Environmental Quality headquarters building, 5301 Northshore Drive, North Little Rock, AR 72118. In the event of inclement weather or other unforeseen circumstances, a decision may be made to postpone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

ADEQ will accept written and electronic comments received by no later than 4:30 p.m. (Central Time) on Tuesday, January 2, 2017. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic comments should be sent to: treecep@adeq.state.ar.us.

A copy of Arkansas's proposed SIP revision is available for public inspection during normal business hours at the Office of Communications in the ADEQ headquarters building in North Little Rock. In addition, Arkansas's SIP revision is available for viewing or downloading on ADEQ's website at: <https://www.adeq.state.ar.us/air/planning/sip/regional-haze.aspx>. Public libraries hosting ADEQ information depositories will also be available to assist interested persons in accessing the SIP from ADEQ's website. These information depositories are located in public libraries at Arkadelphia, Batesville, Blytheville, Camden, Clinton, Crossett, El Dorado, Fayetteville, Forrest City, Fort Smith, Harrison, Helena, Hope, Hot Springs, Jonesboro, Little Rock, Magnolia, Mena, Monticello, Mountain Home, Pochahontas, Russellville, Searcy, Stuttgart, Texarkana, and West Memphis; in campus libraries at the University of Arkansas at Pine Bluff and the University of Central Arkansas at Conway; and in the Arkansas State Library, 900 W. Capitol, Suite 100 in Little Rock.

A R K A N S A S
Department of Environmental Quality

October 27, 2017

Dear Information Depository Librarian:

Please assist the Arkansas Department of Environmental Quality by assisting the public with accessing the materials relevant to the enclosed notice via Arkansas Department of Environmental Quality's web page: <https://www.adeq.state.ar.us/air/planning/sip/regional-haze.aspx>. The information concerns proposed changes to the Arkansas state implementation plan.

The proposed changes are subject to public comment until January 2, 2017. These documents may be removed from the depository after January 2, 2017.

Thank you for your continued service as an information depository for the Arkansas Department of Environmental Quality. If you have any questions, please contact me by telephone at 501-682-0916, or by e-mail at Robinson@adeq.state.ar.us.

Kindest regards,

Kelly Robinson

Arkansas Department of Environmental Quality

Public Notice: Correction

On October 31, 2017, the Arkansas Department of Environmental Quality (ADEQ) published a Public Notice to provide interested persons the opportunity to comment on ADEQ's proposed state implementation plan (SIP) revision. The notice included two typographical errors listing the date of the public hearing and the close of the public comment period as January 2, 2017.

This correction is to notify the public that ADEQ will hold a public hearing on the proposed SIP revision at 2:00 pm on January 2, 2018 in the Commission Room at the ADEQ headquarters building, 5301 Northshore Drive, North Little Rock, AR 72118. This correction is also to notify the public that ADEQ will be accepting written and electronic comments received no later than 4:30 p.m. (Central Time) on Tuesday, January 2, 2018. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic comments should be sent to: treecep@adeq.state.ar.us.

Arkansas Department of Environmental Quality

Public Notice

The Arkansas Department of Environmental Quality (ADEQ) is publishing a Notice of Data Availability (NODA) to provide interested persons the opportunity to review additional information provided by Entergy and to consider this information in developing comments on ADEQ's Regional Haze state implementation plan (SIP) revision proposed on October 31, 2017. In light of the new information, as well as multiple requests for extension of the public comment period, ADEQ is extending the public comment period on the Proposed SIP to January 19, 2018. ADEQ is also postponing the public hearing to January 19, 2018 in response to a request.

ADEQ will hold a public hearing on Friday, January 19, 2018 to receive public comments on the SIP revision. The public hearing will begin at 2:00 p.m. in the Commission Room at the Arkansas Department of Environmental Quality headquarters, 5301 Northshore Drive, North Little Rock, Arkansas 72118. In the event of inclement weather or other unforeseen circumstances, a decision may be made to postpone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

ADEQ will accept written and electronic comments received by no later than 11:59 p.m. Central Time on Friday January 19, 2018. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, Arkansas 72118. Electronic comments should be sent to: treecep@adeq.state.ar.us.

A copy of the NODA and the proposed SIP revision are available for public inspection during normal business hours at the Office of Communications in the ADEQ headquarters building in North Little Rock. In addition, Arkansas's SIP revision and the NODA are available for viewing or downloading on ADEQ's website at: <https://www.adeq.state.ar.us/air/planning/sip/regional-haze.aspx>. Public libraries hosting ADEQ information depositories will also be available to assist interested persons in accessing the SIP and NODA from ADEQ's website. These information depositories are located in public libraries at Arkadelphia, Batesville, Blytheville, Camden, Clinton, Crossett, El Dorado, Fayetteville, Forrest City, Fort Smith, Harrison, Helena, Hope, Hot Springs, Jonesboro, Little Rock, Magnolia, Mena, Monticello, Mountain Home, Pocahontas, Russellville, Searcy, Stuttgart, Texarkana, and West Memphis; in campus libraries at the University of Arkansas at Pine Bluff and the University of Central Arkansas at Conway; and in the Arkansas State Library, 900 West. Capitol, Suite 100 in Little Rock.

Arkansas Department of Environmental Quality Public Notice

The Arkansas Department of Environmental Quality (ADEQ) is publishing this Public Notice to provide interested persons the opportunity to comment on ADEQ's proposed state implementation plan (SIP) revision.

In this SIP proposal, Arkansas has included revisions to address disapproved portions of the Arkansas Regional Haze State Implementation Plan (AR RH SIP), submitted to EPA in 2008 and to replace emission limits for Arkansas subject-to-BART power plants and Entergy Independence included in the 2016 rule "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule" (AR RH FIP). This SIP revises Arkansas's reasonable progress goals and Arkansas's long-term strategy for the first Regional Haze planning period ending in 2018.

ADEQ will hold a public hearing on Tuesday, January 2, 2017 to receive public comments on the SIP revision. The public hearing will begin at 2:00 p.m. in the Commission Room at the Arkansas Department of Environmental Quality headquarters building, 5301 Northshore Drive, North Little Rock, AR 72118. In the event of inclement weather or other unforeseen circumstances, a decision may be made to postpone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

ADEQ will accept written and electronic comments received by no later than 4:30 p.m. (Central Time) on Tuesday, January 2, 2017. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic comments should be sent to:

Arkansas Department of Environmental Quality Public Notice

The Arkansas Department of Environmental Quality (ADEQ) is publishing a Notice of Data Availability (NODA) to provide interested persons the opportunity to review additional information provided by Entergy and to consider this information in developing comments on ADEQ's Regional Haze state implementation plan (SIP) revision proposed on October 31, 2017. In light of the new information, as well as multiple requests for extension of the public comment period, ADEQ is extending the public comment period on the Proposed SIP to January 19, 2018. ADEQ is also postponing the public hearing to January 19, 2018 in response to a request.

ADEQ will hold a public hearing on Friday, January 19, 2018 to receive public comments on the SIP revision. The public hearing will begin at 2:00 p.m. in the Commission Room at the Arkansas Department of Environmental Quality headquarters, 5301 Northshore Drive, North Little Rock, Arkansas 72118. In the event of inclement weather or other unforeseen circumstances, a decision may be made to post-

pone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

ADEQ will accept written and electronic comments received by no later than 11:59 p.m. Central Time on Friday January 19, 2018. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, Arkansas 72118. Electronic comments should be sent to: treecep@adeq.state.ar.us.

A copy of the NODA and the proposed SIP revision are available for public inspection during normal business hours at the Office of Communications in the ADEQ headquarters building in North Little Rock. In addition, Arkansas's SIP revision and the NODA are available for viewing or downloading on ADEQ's website at:

<https://www.adeq.state.ar.us/air/planning/sip/regional-haze.aspx>. Public libraries hosting ADEQ information depositories will also be available to assist interested persons in accessing the SIP and NODA from ADEQ's website. These information depositories are located in public libraries at Arkadelphia, Batesville, Blytheville, Camden, Clinton, Crossett, El Dorado, Fayetteville, Forrest City, Fort Smith, Harrison, Helena, Hope, Hot Springs, Jonesboro, Little Rock, Magnolia, Mena, Monticello, Mountain Home, Pocahontas, Russellville, Searcy, Stuttgart, Texarkana, and West Memphis; in campus libraries at the University of Arkansas at Pine Bluff and the University of Central Arkansas at Conway; and in the Arkansas State Library, 900 West Capitol, Suite 100 in Little Rock.

743740371

FOR IMMEDIATE RELEASE:

January 12, 2018

**ADEQ to Host Public Hearing on Proposed Regional Haze SIP
and Extends Public Comment Period**

NORTHLITTLE ROCK—The Arkansas Department of Environmental Quality (ADEQ) will host a public hearing to receive comments on revisions to the Arkansas Regional Haze State Implementation Plan (SIP). The hearing will be held at 2:00 p.m. on Friday, January 19, 2018 in the Commission Room at ADEQ Headquarters, 5301 Northshore Drive in North Little Rock. The hearing, previously set for January 2, 2018, was rescheduled to provide the public additional time to review the proposal. ADEQ is also extending the comment period by two weeks in response to an additional request.

The Regional Haze Program seeks to address the combined visibility effects of various pollution sources over a wide geographic region with the goal of achieving natural visibility conditions at designated national parks and wilderness areas. In 2008, ADEQ submitted a SIP to address Regional Haze Program requirements for the first implementation period (2008–2018). The 2008 SIP was partially approved in 2012. In 2017, ADEQ submitted a SIP to address nitrogen oxides requirements for power plants for the first implementation period. The Environmental Protection Agency proposed approval of the nitrogen oxides SIP on September 11, 2017.

The current SIP proposal addresses Regional Haze requirements for sulfur dioxide and particulate matter at Arkansas power plants, evaluates controls necessary for ensuring reasonable progress toward natural visibility conditions, and sets reasonable progress goals for the first planning period ending in 2018. The SIP proposal also establishes a long-term strategy for improving visibility.

The hearing will provide the public with an opportunity to present oral and/or written comments on the proposed SIP for ADEQ's consideration. All comments must be received by no later than 11:59 p.m. (Central Time) on Friday, February 2, 2018. Written comments should be mailed to Tricia Treece, Office of Air Quality, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic comments should be sent to: Treecep@adeq.state.ar.us .

CONTACT: Kelly Robinson (Robinson@adeq.state.ar.us or 501.682.0916)

RESPONSIVE SUMMARY FOR STATE IMPLEMENTATION PLAN REVISION:

Revisions to the Arkansas State Implementation Plan

Regional Haze SIP Revision for 2008–2018 Planning Period

Pursuant to Arkansas Code Annotated (Ark. Code Ann.) § 8-4-317(b)(2)(B)(i), the Arkansas Department of Environmental Quality (ADEQ or “Department”) must prepare a record of the public process in the form of a written response to each issue raised during the public comment period. A responsive summary groups public comments into similar categories and explains why ADEQ accepts or rejects the rationale for each category.

On October 31, 2017, ADEQ proposed a state implementation plan (SIP) revision to address certain disapproved portions of Arkansas’s 2008 Regional Haze SIP. The SIP revision has been referred to by commenters as the Phase II SIP, the draft SIP, and the proposed SIP. For consistency, the proposed SIP revision is referred to as the “Proposed SIP” in the comment summaries and responses below.

On January 19, 2018, ADEQ Associate Director Stuart Spencer acted as Hearing Officer and conducted a public hearing for SIP revisions. The public comment period ended February 2, 2018. Comments received during the public comment period are summarized and a response for each is provided below.

Comment 1:

Some commenters expressed concerns that their enjoyment of Class I areas was impacted by visibility impairment. One commenter recounted difficulty in getting good pictures at Class I areas due to haze along rivers and trails. Another commenter stated that Arkansas’s biggest asset is nearby wilderness, but that haze pollution obstructs views. Commenters expressed the desire not to see haze when visiting natural areas.

Response 1:

Visibility has dramatically improved in Arkansas since 2004. In fact, visibility in the Natural State is approaching natural background conditions much more rapidly than required under the Regional Haze Rule. Arkansas is making substantial progress in addressing regional haze in its Class I areas and is ahead of schedule in meeting its own proposed progress goals and the uniform rate of progress for this first planning period ending in 2018. This means that Arkansas is well on track to reaching background visibility conditions no later than 2064.

Arkansas has many beautiful natural assets that should be both appreciated and protected. The goal of the Regional Haze Program is to assist in collective appreciation and protection of those

assets. Haze is caused by particles, both natural and anthropogenic, which absorb and scatter light. Haze reduces the clarity and color of what can be seen. Particulate-caused haze is not the only culprit in obstructing the view of Arkansas’s natural beauty. Often, the very natural occurrence of fog or mist, tiny water droplets in the atmosphere, may be mistakenly categorized as haze. In addition, not all haze-forming particles come from anthropogenic sources of pollution. Some haze-forming particles, such as crustal material, soil, and sea salt, occur naturally.

The United States Environmental Protection Agency (EPA) established a goal for achieving natural visibility in Class 1 areas by 2064. Arkansas is on track to achieve this goal. Figures 1 and 2 show the progress toward achieving natural visibility in comparison to the glide path¹ toward natural visibility in 2064.²

This comment does not necessitate changes to the Proposed SIP.

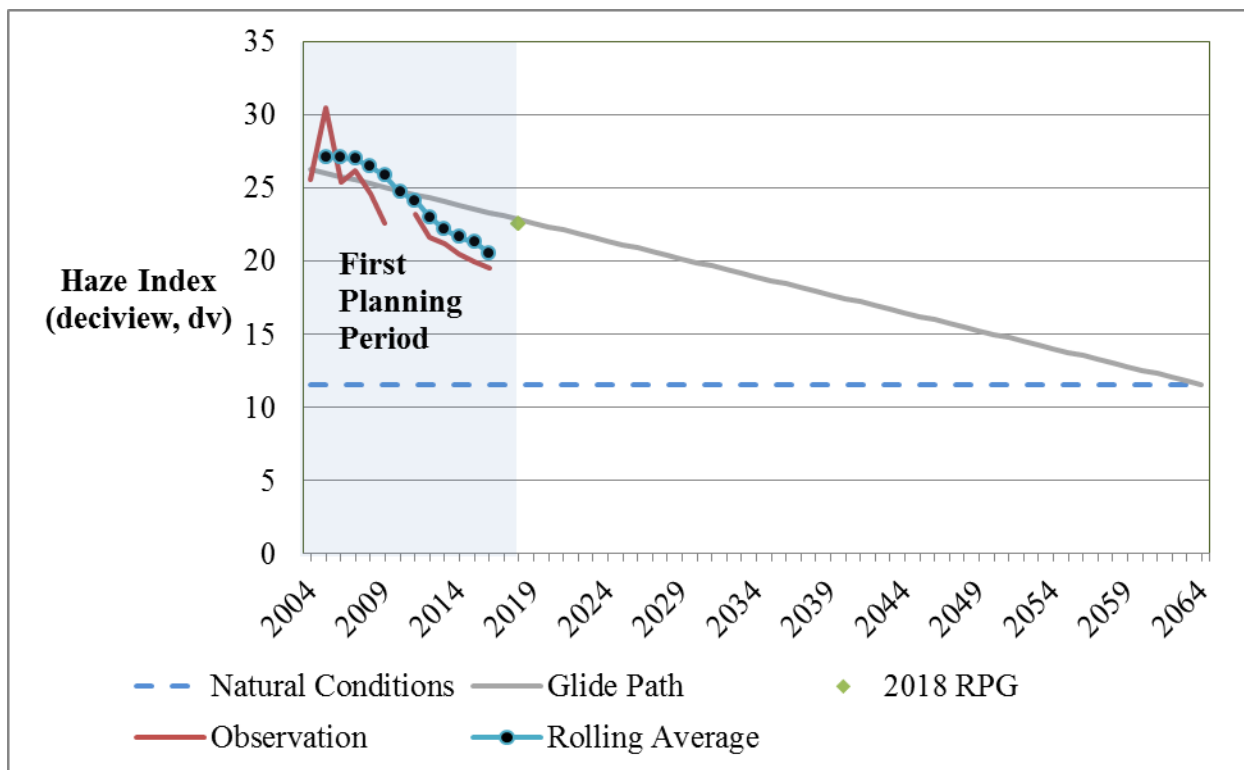

Figure 1 Visibility Progress at Caney Creek – 20% Worst Days

¹ The glide path is the rate of uniform progress needed to achieve natural visibility conditions by 2064.

² Figures 1 and 2 are updates to Figures 11 and 12 in the Proposed SIP. These figures have been updated so that the rolling average is inclusive of the current year and four previous years rather than reflecting the five previous years and to include 2016 data. 2000–2016 visibility data included in Figures 1 and 2 were obtained from: Visibility Status and Trends Following the Regional Haze Rule Metrics: IMPROVE Aerosol, Regional Haze Rule II (New Equation), with substituted data. Caney Creek, Upper Buffalo <http://views.cira.colostate.edu/fed/SiteBrowser/Default.aspx>.

Figure 2 Visibility Progress at Upper Buffalo – 20% Worst Days

Comment 2:

One commenter recommended a book entitled “What has Nature Done for Me Lately.” The commenter stated that the book illustrates the treatment of natural resources and asserts that natural capital is the base on which we all live. The commenter asserted that natural capital is more profitable and economically beneficial to Arkansas and to the world. One commenter noted the natural beauty of the Ozarks. Some commenters stated that Arkansas will not live up to the “Natural State” nickname. One commenter stated that Arkansas should be renamed the “Toxic State” and indicated the resulting impact on attracting businesses and employees to the state. One commenter stated that Arkansas will no longer be the “clean, pristine State that attracts tourists from all over the world as it does now.”

Response 2:

ADEQ agrees with the commenters that Arkansas’s natural capital is of both aesthetic and economic value to the State; however, ADEQ disagrees with those commenters that implied that the Proposed SIP will result in Arkansas no longer being clean or pristine. The Proposed SIP requires measures that will further enhance the natural beauty of Arkansas wilderness areas by reducing emissions of visibility-impairing pollutants. Arkansas Class I areas are already experiencing more visibility improvement progress than anticipated (See Figures 1 and 2) and the control measures included in the Proposed SIP, other Clean Air Act requirements, and

changes in generation due to market forces as described in the long term strategy of the Proposed SIP will result in further improvements in visibility at Arkansas's Class I areas.

See also Response to Comment 1.

This comment does not necessitate changes to the Proposed SIP.

Comment 3:

Some commenters expressed concerns with respect to public health as a result of emissions from coal-fired power plants. Specifically, commenters noted coal-fired power plants emit mercury, sulfur oxides (SO_x), nitrogen oxides (NO_x), particulate matter, and other noxious gases that can impact health. One commenter noted that Arkansans have high rates of diseases that can be linked to particulate matter and other noxious gases. Commenters also noted that these pollutants impact water and soil quality. One commenter explained that when smoke and fumes dissipate into the air, they are still there and we will continue to feel and see the effects.

Several commenters explained that they or their relatives had existing health conditions that can be exacerbated by pollution. Commenters asserted that current emissions from Arkansas coal plants are causing smog in St. Louis, MO. Some commenters noted that air quality in St. Louis was causing or exacerbating their health problems. One commenter noted that they changed filters on a CPAP machine more in Arkansas than in Mississippi as a result of the air quality. The commenter also compared the soil in South Arkansas to the ash heaps in Saltville, Virginia, which is now a superfund site. Commenters further noted that health impacts of pollution have economic costs.

Some commenters expressed concerns that the Proposed SIP would result in harming air quality and human health.

One commenter noted that new data about the Clean Air Act indicates that it saved 80,000 more lives than expected.

Response 3:

ADEQ acknowledges the commenter's concerns with respect to the impacts that pollutants have on public health; however, ADEQ disagrees with comments that the Proposed SIP will result in harming air quality and human health. The Proposed SIP directly addresses manmade visibility impairment in Arkansas and surrounding states in accordance with Clean Air Act §169A and EPA's Regional Haze Regulations. Nevertheless, ADEQ notes that all areas of Arkansas are in attainment with all national health-based air quality standards. EPA sets national ambient air quality standards (NAAQS) for six common pollutants—referred to as criteria pollutants. These pollutants include ozone, particulate matter, nitrogen dioxide (NO₂), sulfur dioxide (SO₂), carbon monoxide, and lead. The NAAQS are established based on a rigorous evaluation of controlled exposure studies, clinical studies, epidemiological studies, and health risk

assessments. The standards are set at a level to protect human health, including sensitive populations, with an adequate margin of safety and to protect public welfare, including protection against damage to animals, crops, vegetation and buildings and visibility degradation.

Arkansas monitoring data shows that all areas of Arkansas are in attainment with EPA’s NAAQS, including for those pollutants known to impact visibility or with precursor pollutants that impact visibility. ADEQ operates an ambient air quality monitoring network in accordance with federal requirements. Monitors are sited based on a number of factors:

1. Where the highest concentration is expected to occur in the area covered by the monitor (usually determined through modeling);
2. What the expected representative concentrations are in areas of high population density;
3. What impacts on ambient pollution levels significant sources or source categories may have; and
4. What the background concentration levels are.

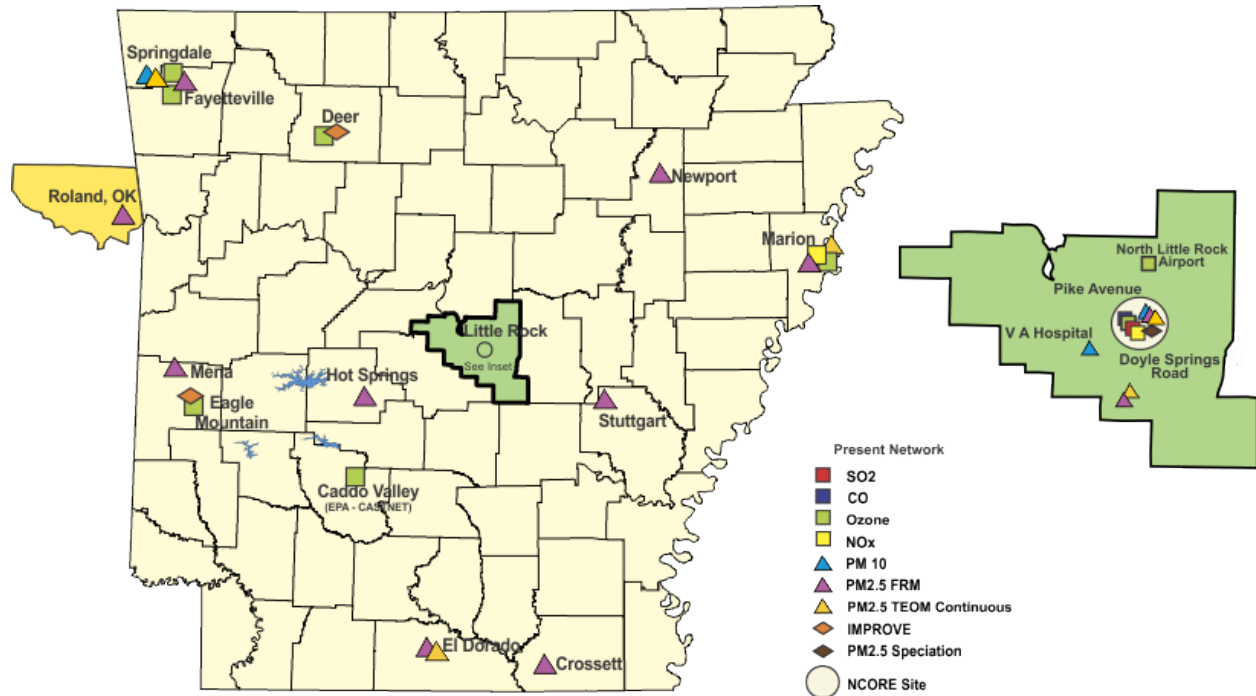

Locations of the various monitor types in Arkansas are listed in Table 1 and depicted in the Figure 3.

Table 1 Pollutants Monitored by the Arkansas Ambient Air Monitoring Network

Pollutant	Number of Monitors	Locations
Ozone	8	Clark County Crittenden County Newton County Polk County Pulaski County Washington County
Coarse Particulate Matter (PM ₁₀)	3	Pulaski County Washington County
Fine Particulate Matter (PM _{2.5})	14	Arkansas County Ashley County Crittenden County Garland County Jackson County Polk County Pulaski County Union County Washington County Sequoyah County (Oklahoma)
Carbon Monoxide	1	Pulaski County
Nitrogen Dioxide	2	Crittenden County Pulaski County

Sulfur Dioxide	1	Pulaski County
Lead	1	Pulaski County

Figure 3 Locations of Arkansas Regulatory Monitors

The figures below reflect the air quality for PM_{2.5}, ozone, NO₂, and SO₂. Decreasing design values are noticeable for PM_{2.5} and ozone. NO₂ and SO₂ design values have remained well below the level of the NAAQS. The figures represent a visual analysis of the overall quality of air over a ten-year period.

Figure 4 Annual PM_{2.5} Design Values by Year³

³ ADEQ (2018). "2017 State of the Air." Figures 3-6 at Pgs 28-37. <https://www.adeg.state.ar.us/air/state-of-air/>

Figure 5 Eight-Hour Ozone Design Values by Year

Figure 6 Annual Nitrogen Dioxide Design Values by Year

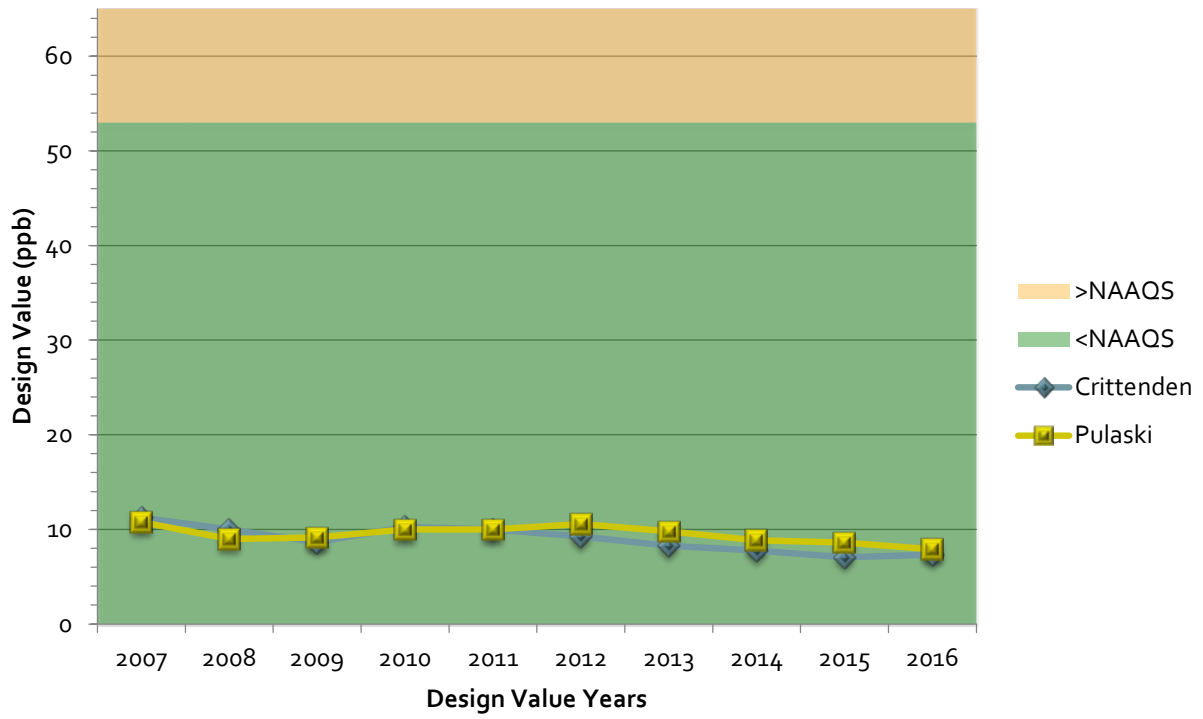

Figure 7 One-Hour SO₂ Design Values by Year

The goal of the Regional Haze Rule is to address man-made sources of visibility impairment in Class I Areas. The structure of Clean Air Act provides for the protection of human health through other EPA rules and programs. However, the Sierra Club’s effort with their October 10, 2017 memorandum entitled “*Ozone Impacts in 2011 from White Bluff and Independence Power Plants in Arkansas*” is not relevant to Regional Haze program because it attempts to address NAAQS interstate transport requirements under Clean Air Act Section 110(a)(2)(D)(i)(I). The Proposed SIP addresses visibility requirements under the Regional Haze Rule pursuant to Clean Air Act Section 169A. Sierra Club’s October 10, 2017 memorandum does not address visibility impairment to Class I Areas.

Furthermore, the information presented in the Sierra Club’s October 10, 2017 memorandum is based on outdated 2011 data that does not represent present day data. Sonoma Technology, Inc. (STi) used the Comprehensive Air Quality Model with Extensions (CAMx) photochemical model to describe ozone concentrations, relative to the 2008 ozone NAAQS in the St. Louis-St. Charles-Farmington, Missouri-Illinois Metropolitan Statistical Area (MO-IL MSA). Although this memorandum is dated October 10, 2017, STi used NOx emissions emitted during the 2011 ozone season (May to September) from four Electrical Generating Units (EGUs) located in Arkansas. Actual emission rates for these four EGUs are publicly available for every year, and the U.S. EPA’s 2011 CAMx modeling platform uses 2011 meteorological data, along with other 2011 data inputs. Comparisons of the 2011 data to the most recently available data (2017)

indicate that the 2011 data does not accurately represent more recent EGU emissions or ozone concentrations in the MO-IL MSA. From 2011 to 2017, ozone season NO_x emissions decreased by thirty-one percent at the White Bluff EGU and decreased by nineteen percent at the Independence EGU⁴. Similarly, the ozone NAAQS three-year design value concentration for the MO-IL MSA decreased from 0.082 parts per million (ppm) in 2011–2013 to 0.072 ppm in 2014–2016 (the most recent design value years available), which is below the 2008 NAAQS of 0.075 ppm.⁵ Based on 2013–2015 data, on June 27, 2016⁶ and March 1, 2018⁷ the U.S. EPA determined that both the Missouri and Illinois parts of the MO-IL MSA were below the 2008 ozone NAAQS.

In addition, it should be noted that Arkansas’s Regional Haze SIP Revision that was finalized on October 31, 2017 and approved by EPA on February 12, 2018 addressed NO_x requirements from EGUs for Regional Haze. The Proposed SIP addresses Regional Haze requirements with respect to SO₂ and particulate matter for EGUs, which are not precursors to ozone.

ADEQ also notes the commenters’ concerns with respect to soil quality and water quality. ADEQ considered, among other factors, energy and non-air environmental impacts of controls required in the Proposed SIP. None of the retrofit technologies considered in the Proposed SIP were eliminated based on this factor.

ADEQ acknowledges data providing evidence that the Clean Air Act has saved lives. The framework of the Clean Air Act provides for a system of cooperative federalism in which EPA sets standards and issues framework regulations that the states then use to develop robust air quality plans and programs based on state-specific circumstances and expertise. The roles of EPA and states in developing plans for protection of visibility are specified in Clean Air Act § 169A. The Proposed SIP complies with the requirements under Clean Air Act § 169A and the EPA regulations for the first planning period.

This comment does not necessitate changes to the Proposed SIP.

Comment 4:

One commenter stated that ADEQ is required under Ark. Code Ann. § 8-4-312(9) and (12) to take into account “the effect on normal human health of particular air contaminants” and “the interference with reasonable enjoyment of life by persons in the area and conduct of established enterprises that can reasonably expected.” The commenter further stated that the purpose of the Clean Air Act is to “protect and enhance the quality of the Nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.”⁸ The

⁴ <https://ampd.epa.gov/ampd/>

⁵ <https://www.epa.gov/air-trends/air-quality-design-values#previous>

⁶ Federal Register Vol. 81, No. 123, 41444

⁷ Federal Register Vol. 83, No. 41, 8756

⁸ H.R. Conf. Rep. 95-564, 1977 U.S.C.C.A.N. 1502, 1570

commenter points out that visibility impairing pollutants also cause significant health impacts. The commenter notes that the emission reductions that would have been required under EPA's 2016 Arkansas Regional Haze federal implementation plan (FIP) would have resulted in quantifiable health benefits across fourteen states. The commenter asserts that replacement of EPA's FIP with ADEQ's proposed SIP would allow Arkansas EGUs to continue to emit sulfur dioxide (SO₂) at the same level as in previous years resulting in harm to public health in Arkansas and neighboring states.

Response 4:

ADEQ agrees that Ark. Code Ann. § 8-4-317 requires ADEQ to take into consideration the factors set forth in Ark. Code Ann. § 8-4-312, which include the two factors raised by the commenter. ADEQ included an explanation of how these factors were considered in the Proposed SIP.

ADEQ analyzed the factor of “[i]nterference with reasonable enjoyment of life by persons in the area and conduct of established enterprises that can reasonably be expected from air contaminants” in the following manner:

Visibility improvements are expected to occur at Arkansas Class I areas in the State as a result of the emissions limitations included in this SIP. Visitors to Caney Creek and Upper Buffalo are expected to enjoy these improvements. Persons that conduct tourism enterprises may also benefit as a result of the [Best Available Retrofit Technology (BART)] controls required in this SIP. Costs of control may be passed on to customers of the sources for which ADEQ is establishing emissions limitations; however, these costs are anticipated to be lower in this SIP than in the AR RH FIP that this SIP seeks to replace.⁹

However, Ark. Code Ann. § 8-4-317 states that the Ark. Code Ann. § 8-4-312 factors must only be considered “as applicable.” With regard to “the effect on normal human health of particular air contaminants,” ADEQ determined that “[t]his factor is not applicable to the regional haze program, which targets visibility improvements.”¹⁰ Ark. Code Ann. § 8-4-312 does not compel the Department to apply these factors without regard to applicability in the implementation of a federal program such as regional haze intended specifically to address visibility when a separate program exists to address the factors mentioned by the commenters.

The Clean Air Act sets forth standards and emissions limitations intended to address the impact to human health in sections that are separate and distinct from the sections intended to address visibility impact on Class I areas through the regional haze program. EPA sets NAAQS to address concentrations of certain air pollutants considered harmful to public health and welfare

⁹ Proposed SIP at p. 13.

¹⁰ *Id.*

under sections 109 and 110 of the Clean Air Act. Arkansas is currently in attainment for all NAAQS. See Response 3. In contrast, the regional haze program was developed under authority provided by Congress in Section 169A and B of Clean Air Act specifically to address visibility. As a result of this structure, ADEQ is not required perform a written consideration of “the effect on normal human health of particular air contaminants.” This factor is not “applicable” within the meaning of Ark. Code Ann. § 8-4-317.

This comment does not necessitate changes to the Proposed SIP.

Comment 5:

One commenter related the Regional Haze Rule to the Clear Skies Act of 2003, which was not passed. The commenter stated that the Regional Haze Rule would have accomplished similar benefits in terms of reductions in illnesses, missed work days, and missed school days as were estimated for the Clear Sky Act and that the benefits would outweigh the costs.

Response 5:

The Clear Sky Act of 2003 was a federal initiative that, if passed, laid out a path for the reduction of power plant emissions. However, the Act did not pass. In addition, the Clear Sky Act of 2003 is not part of the Clean Air Act § 169A and B and EPA Regional Haze Regulations framework with which the Proposed SIP must comply.

The Proposed SIP meets the requirements for the Arkansas of Clean Air Act § 169A and EPA Regional Haze Regulations. Although the Proposed SIP addresses visibility, ADEQ notes that Arkansas is in full attainment of federal health-based air quality standards. See Response 3.

This comment does not necessitate changes to the Proposed SIP.

Comment 6:

Some commenters expressed their views on the role of the State in protecting natural resources. One commenter exhorted that given the climate of national government, it falls to state and local governments to do everything they can to help protect natural resources. Another commenter stated that ADEQ is in a position to preserve fragile ecosystems that sustain life, to protect the beauty of the natural world and visibility in wilderness areas. Another commenter stated that ADEQ is best equipped to consider how to make measurable and reasonable progress toward natural visibility goals by considering the key characteristics of individual facilities, applicability of specific technologies, economic considerations, and site-specific characteristics.

Response 6:

ADEQ acknowledges the commenters views on the role of the State in protecting natural resources. The Proposed SIP is consistent with the mission statement of ADEQ. This Proposed SIP is developed with the goal of assuring “reasonable progress toward meeting the national goal

of preventing any future, and remedying any existing, impairment of visibility in mandatory Class I Federal areas which impairment results from manmade air pollution” as stated in the Regional Haze Rule.¹¹ ADEQ anticipates that the improvements from the Proposed SIP will create more visibility improvement than is necessary to achieve the reasonable progress goals for the 2008–2018 planning period. See Response 1.

ADEQ agrees that we are best equipped to consider how to make measurable and reasonable progress toward natural visibility goals by considering the key characteristics of individual facilities, applicability of specific technologies, economic considerations, and site-specific characteristics. In fact, Congress recognized that states should have the primary role in implementing air quality programs for these reasons. Under Section 110(a)(3), the Clean Air Act states that “Congress finds [...] that air pollution prevention [...] and air pollution control at its source is the primary responsibility of States and local governments.” ADEQ intends for this SIP revision to restore the primary role for implementing the Regional Haze Program to Arkansas, consistent with Congressional intent for Clean Air Act programs for stationary sources. Regional Haze programmatic requirements with respect to NO_x emissions from EGUs have already been returned to the State as a result of EPA’s February 12, 2018 approval of ADEQ’s 2017 Regional Haze SIP revision.

This comment does not necessitate changes to the Proposed SIP.

Comment 7:

Some commenters expressed concerns with the 2064 goal of achieving natural visibility conditions. One commenter noted that there are fifty-six years between the submission of the 2008 plan and 2064. The commenter asserted that this was not a reasonable length of time to work on this problem. Another commenter stated that taking baby steps is not enough to make reasonable progress and is the same as doing nothing. The commenter stated that the Proposed SIP is too little, too late for the Natural State.

Response 7:

ADEQ did not establish the 2064 goal for achieving natural visibility conditions. This date was established in the EPA 1999 Regional Haze Regulations, which instructed States to conduct certain analyses and set reasonable progress goals covering ten-year periods aimed at reaching natural background conditions on the haziest days within sixty years.¹² This target date was set in part based on EPA’s expectation that continued visibility progress will be possible as “industrial facilities built in the latter half of the 20th century will reach the end of their ‘useful lives’ and are retired and/or replaced by cleaner, more fuel-efficient facilities.”¹³ In addition, EPA noted the

¹¹ 40 C.F.R. § 51.300

¹² EPA (1999). “Regional Haze Regulations; Final Rule” (64 FR 35714)

¹³ Id. at 35732

agency's anticipation that further innovations in control technologies will enable new facilities to achieve lower emissions rates.¹⁴

Arkansas Class I areas are making greater progress toward natural visibility than would result from a uniform rate of progress (URP or "glide path") toward the 2064 goal, even before consideration of the controls included in the Proposed SIP. See Figures 1 and 2. The visibility improvements observed in these Class I areas are a result of reductions from State and federal programs; including new source performance standards for a variety of source types, vehicle emissions standards, changes in NAAQS; innovations in emissions control technologies; retirement or reconstruction of older facilities; and market-driven changes in electricity generation. The Proposed SIP includes further emissions controls that will keep Arkansas Class I areas on track for achieving natural visibility conditions on or before 2064. In a SIP due in 2021, ADEQ will revisit whether additional controls beyond those included in the Proposed SIP, the 2008 Regional Haze SIP, the 2017 Regional Haze SIP Revision addressing NO_x, and emission limits for Domtar Ashdown Mill¹⁵ are necessary to ensure continued reasonable progress toward natural visibility.

This comment does not necessitate changes to the Proposed SIP.

Comment 8:

Some commenters recommended that ADEQ revise its proposed plan to include dry flue gas desulfurization ("Dry FGD" or "scrubbers") at Entergy's White Bluff and Independence power plants. Commenters pointed out that SWEPCO recently installed a scrubber at its Flint Creek coal-fired power plant and that it was time for the same pollution control equipment at White Bluff and Independence. Some commenters also pointed out that ADEQ's 2008 SIP contemplated scrubbers for White Bluff and asserted that the State is now backtracking. Commenters noted that the White Bluff and Independence are among the largest coal-burning units in the country that lack modern pollution controls. One commenter asserted that, by not requiring scrubbers, the Proposed SIP is ensuring continued damage to people and the environment as a result of continued haze and particle pollution.

Another commenter opposed Dry FGD for White Bluff and Independence due to the generation of waste from this technology. The commenter specifically referred to scrubber waste from the John W. Turk Jr. coal-fired power plant. The commenter stated that scrubber waste is diluted with river water and then released into streams.

¹⁴ Id. at 35732

¹⁵ Emission limitations for Domtar are contained in EPA's 2016 "Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule." ADEQ is working with Domtar to re-evaluate limitations based on changes in their operations that have reduced emissions at the Ashdown Mill; however, ADEQ did not propose any changes to emission limits for the Ashdown Mill in the Proposed SIP.

Response 8:

ADEQ assessed available retrofit technologies for both White Bluff and Independence. ADEQ's assessment of available control technologies and determinations were discussed in Section IV.D. of the Proposed SIP for White Bluff and in Section V.C.&D. of the Proposed SIP for Independence. Based on ADEQ's assessment, the Department determined that Dry FGD should not be required for White Bluff or Independence for the 2008–2018 Regional Haze Planning Period.

Circumstances between the SWEPCO Flint Creek power plant and the White Bluff and Independence power plants differ. Both Flint Creek and White Bluff are subject to BART requirements based on their emissions, source category, 2001–2004 visibility impact, and age; however, Flint Creek has not indicated any anticipated changes in operation that are State or federally enforceable that would impact its remaining useful life. Entergy has indicated for White Bluff that they anticipate ceasing coal-fired operations by the end of 2028 and have requested to take an enforceable requirement to that effect. Therefore, the remaining useful life factored into ADEQ's BART is much shorter for White Bluff than for Flint Creek. As such, the amortization period for the controls results in much higher annual costs due to the period of time that White Bluff would still be operational. Unlike White Bluff and Flint Creek, Independence does not fall within the age range of facilities that are subject to BART. ADEQ did assess whether controls were necessary to ensure reasonable progress in Section V of the Proposed SIP and determined that no additional controls beyond BART were necessary to achieve reasonable progress during the 2008–2018 planning period.

ADEQ disagrees with the commenter that not requiring scrubbers in the Proposed SIP will ensure continued damage to people and the environment. Arkansas monitoring data shows that all areas of Arkansas are in attainment with EPA's NAAQS. See Response 3. Dry FGD controls at White Bluff and Independence are not necessary to ensure continued attainment with the NAAQS. The Proposed SIP is intended to address visibility in accordance with Clean Air Act §169A and EPA's Regional Haze Regulations.

The responses to Comments 20 and 25 in this document further explain ADEQ's consideration of comments regarding Dry FGD at White Bluff and Independence.

ADEQ notes the commenter's concern with waste generated by scrubbers entering streams. Waste generated by control technologies was considered pursuant to the statutory requirement for consideration of energy and non-air quality environmental impacts. The Dry FGD technology considered in this Proposed SIP would result in a solid waste, which is disposed of through landfilling, and thus there would be no new discharge into streams.

This comment does not necessitate changes to the proposed SIP.

Comment 9:

Some commenters requested that ADEQ retain source-specific NOx limits in place of a trading program. Commenters noted that the trading program would allow Entergy to buy pollution reduction credits in other states while continuing to pollute in Arkansas. The commenters also asserted that the trading program allow some areas of the state to be more polluted than others.

One commenter stated that ADEQ should not retain source-specific NOx limits in place of the trading program.

Response 9:

ADEQ did not include in the Proposed SIP any changes to previous determinations with respect to NOx for subject-to-BART EGUs and reasonable progress. On October 31, 2017, ADEQ submitted to EPA a final SIP revision that relied upon the Cross-State Air Pollution Rule (CSAPR) in place of source-specific NOx emission limits for EGUs. The 2017 SIP is consistent with federal requirements for an alternative to BART limits under 40 CFR 51.308(e)(4). Furthermore, EPA provided evidence demonstrating that implementation of the CSAPR program would achieve greater reasonable progress than BART.¹⁶ EPA further affirmed the continued validity of the use of CSAPR in place of source-specific BART determinations on September 29, 2017.¹⁷ On March 20, 2018, the United States Court of Appeals for the District of Columbia denied the petition for review of EPA's final action to allow states to use CSAPR in place of source-specific BART.¹⁸ ADEQ's 2017 SIP, which established the use of CSAPR as an alternative to source-specific BART NOx emission limitations for Arkansas EGUs was approved by EPA on February 12, 2018.¹⁹ EPA also withdrew source-specific NOx emission limitations for EGUs from the FIP on February 12, 2018.²⁰

This comment does not necessitate change to the Proposed SIP.

Comment 10:

Some commenters recommended replacement of White Bluff and Independence—and coal plants in general—with other generation technology, particularly renewable energy technology, such as wind and solar. One commenter also recommended transitioning to natural gas. Another commenter recommended replacement of coal, gas, and nuclear with solar and wind power. One commenter stated that we can grow the economy, invest in clean energy jobs, and have cleaner air and water. One commenter questioned why utilities are “dragging their feet” in adopting new renewable technologies. Some commenters noted that availability and cost-savings potential of renewable energy technologies. One commenter asserted that until the transition to a clean

¹⁶ 77 FR 33642

¹⁷ 81 FR 7894

¹⁸ USCA Case #12-1342 Document #1722974 Filed: 03/20/2018

¹⁹ 83 FR 5915

²⁰ 83 FR 5927

renewable energy economy is complete, there will still be people, nature, and natural areas exposed to pollution at unacceptable levels.

Some commenters criticized continued use of coal as a fuel. One commenter stated that a massive amount of haze in Arkansas is caused by exhaust in coal-fired electric power in Arkansas. Some commenters noted short-and long-term effects of pollution from coal. Others stated that coal was outdated.

Response 10:

The commenter's requests and comments regarding the composition of the energy-generating portfolio of utilities and the transition to renewable energy are beyond the scope of the authority of ADEQ, as well as the scope of the Regional Haze Rule. Under Title 23 of the Arkansas Code, Arkansas law vests the Arkansas Public Service Commission with the authority to regulate public utilities, which includes electric utilities.

The regional haze program is intended to address the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas that results from manmade air pollution.²¹ The program is not intended to address the composition of a state's electricity-generating portfolio.

This comment does not necessitate changes to the Proposed SIP.

Comment 11:

Several commenters suggested that clean air, health, and lives should be prioritized. Commenters indicated that clean air is one of the most basic issues for quality of life and that all living things deserve to breathe clean air. Commenters expressed the need to recognize the damage people are causing to the planet and to find solutions to fix it. Commenters urged ADEQ to prioritize the health of people over the wealth of energy companies.

Response 11:

ADEQ acknowledges and shares the commenters' priorities of clean air, as well as human and environmental health. The ADEQ Office of Air Quality works to implement programs that protect air quality to enhance the lives and health of all Arkansans and visitors to the State, while fostering responsible economic expansion opportunities. This is achieved through planning, regulatory development, permitting, inspection, and enforcement of State and federal rules. ADEQ has developed plans to ensure attainment and maintenance of the NAAQS, which protect public health and the environment. Arkansas is in full attainment of all the NAAQS. See Responses 3 and 8.

²¹ 42 U.S.C.A. § 7491

The Proposed SIP covers a different program area: visibility. The Proposed SIP seeks to address EPA Regional Haze Regulations and Clean Air Act §169A requirements for state plans to improve visibility at Class I areas. The Proposed SIP was written within the framework established by the Regional Haze Regulations and statute—and in accordance with EPA guidance for the first planning period (2008–2018)—which require ADEQ to consider, among other things, the cost of compliance. ADEQ notes that, under Arkansas law, energy companies are permitted to recover costs related to installation of emissions control technologies at EGUs required by the final SIP from electricity ratepayers subject to approval by the Arkansas Public Service Commission.

This comment does not necessitate changes to the Proposed SIP.

Comment 12:

Some commenters agreed with ADEQ’s determination that the Proposed SIP satisfied interstate transport requirements for visibility impairing pollutant; however, some commenters disagreed.

Some commenters supported ADEQ’s determination that no additional controls, provisions, or measures are necessary to satisfy interstate visibility transport provisions of 42 USC 7410(a)(2)(D)(i)(II) because ADEQ has not identified any measures included in any other state’s implementation plan to protect visibility that would be interfered with by emissions from any sources within Arkansas.

Other commenters stated that ADEQ’s analysis of measures for out-of-state Class I areas is inconsistent with both the statute and the Regional Haze Rule, both before and after the 2017 RHR Amendments. The commenters claimed that ADEQ attempts to avoid the “contribute to visibility test” of 40 CFR 51.308(f)(3)(II)(B) by substituting a non-interference standard. The commenters argued that ADEQ’s Proposed SIP fails to demonstrate that there are no additional emission reduction measures for sources that contribute to out-of-state Class I area visibility impairment that would be appropriate to include in the SIP. The commenters claimed that the contribution of Arkansas sources to light extinction at Missouri Class I areas was projected to increase between 2002 and 2018. The commenters asserted that ADEQ must require Independence units 1 and 2 to meet an emission limit of 0.06 lb SO₂/MMBtu, based on Dry FGD, to improve visibility in Missouri’s Class I areas.

The commenters likened the Proposed SIP’s explanation of why no additional controls are necessary to make reasonable progress in Missouri’s Class I areas to Nebraska and EPA’s rationale in considering whether controls were required at the Gerald Gentleman power plant (GGS) in Nebraska to make reasonable progress.²² The commenter asserted that the State of Nebraska and EPA relied upon the same arguments that ADEQ makes in the Proposed SIP. The

²² 77 FR 40150-at 40155-40156

commenters stated that EPA sought and the court granted a remand to reconsider this rationale for its reasonable progress control determination for GGS.

Some commenters requested that ADEQ take responsibility as a good neighbor to stop pollution from Arkansas coal plants from impacting Missouri. These comments were in association with a description of a study by Sonoma Tech, funded by the Sierra Club, which indicated that White Bluff and Independence contributed to nonattainment for the 2008 ozone standard in St. Louis.

One commenter stated that the scientific facts prove that what we do in one place has effects positively or adversely elsewhere.

Response 12:

ADEQ acknowledges those commenters who agree with ADEQ's determination that no additional controls are necessary to satisfy interstate visibility transport obligations for the first planning period.

ADEQ disagrees with those commenters that claimed that the Proposed SIP fails to demonstrate that there are no additional emission reduction measures for sources that contribute to out-of-state Class I area visibility impairment that would be appropriate to include in the SIP. As monitoring data included in the Proposed SIP demonstrates, Hercules Glades and Mingo Wilderness Areas are well on their way to achieve Missouri's reasonable progress goals. Therefore, no additional controls from Arkansas sources are necessary to ensure reasonable progress at Missouri Class I areas during the first planning period. More recent data for 2016, illustrated in Figures 8 and 9 below, demonstrates that Hercules Glades and Mingo Wilderness areas continue to be on track to achieve Missouri's reasonable progress goals.²³ In fact, both the 2016 observed twenty percent worst (haziest) average and the most recent five-year average (2012–2016) deciview values on the twenty percent worst days for 2016 were below Missouri's reasonable progress goals at both Missouri Class I areas.

²³ Figures 7 and 8 are updates to Figures 13 and 14 in the Proposed SIP. These figures have been updated so that the rolling average is inclusive of the current year and four previous years rather than reflecting the five previous years and to include 2016 data. 2000–2016 visibility data included in Figures x and y were obtained from: Visibility Status and Trends Following the Regional Haze Rule Metrics: IMPROVE Aerosol, Regional Haze Rule II (New Equation), with substituted data. Hercules Glades, Mingo <http://views.cira.colostate.edu/fed/SiteBrowser/Default.aspx>. Note: Missouri DNR revised its natural baseline conditions for Mingo on the twenty percent haziest days from 12.4 deciviews to 11.3 deciviews in their 2012 technical supplement to their 2009 Regional Haze SIP. <https://dnr.mo.gov/env/apcp/reghaze/regional-haze-jan-30-2012.pdf>.

Figure 8 Hercules Glades Reasonable Progress Assessment – 20% Worst Days

Figure 9 Mingo Reasonable Progress Assessment – 20% Worst Days

On October 27, 2017, ADEQ sent a letter to Missouri Department of Natural Resources (Missouri DNR) to provide the opportunity for consultation on the Proposed SIP. As part of this consultation, Missouri had the opportunity to inform ADEQ whether they thought any additional controls were necessary to achieve reasonable progress at Missouri Class I areas. Missouri DNR did not provide comments on the Proposed SIP. In addition, ADEQ also engaged in interstate consultation during the development of the State’s 2008 Regional Haze SIP.

ADEQ disagrees with those commenters that asserted modeling data projected an increase between 2002 and 2018 in contribution from Arkansas sources to light extinction at Missouri Class I areas. CENRAP projections demonstrate a fourteen percent reduction between 2002 and 2018 in light extinction attributed to Arkansas sources for Hercules Glades and an eighteen percent reduction in light extinction attributed to Arkansas sources for Mingo Wilderness.²⁴ See Figures 9 and 10.

Figure 10 Comparison of Projected Light Extinction at Hercules Glades on the Hazeiest Twenty Percent Days Due to Particulate Species Attributed to Arkansas Sources

²⁴ Percent change in total light extinction associated with particulate species attributed to Arkansas sources from CENRAP PSAT Tool worst 20% projected extinction for Mingo and Hercules Glades 2002 and 2018 data sets, queried source region: Arkansas.

Figure 11 Comparison of Projected Light Extinction at Mingo on the Haziest Twenty Percent Days Due to Particulate Species Attributed to Arkansas Sources

ADEQ notes that the 2017 RHR Amendments specified requirements, including a four factor analysis, for sources that are reasonably anticipated to contribute to visibility impairment in a Class I area in another State. However, the 2017 RHR Amendments only apply to the second period and beyond. The preamble to the 2017 RHR Amendments explicitly states that “EPA is making changes to the requirements that states [] have to meet for the second and subsequent implementation periods.”²⁵ Prior to the 2017 RHR Amendments, the Regional Haze Rule stated:

Where the State has emissions that are reasonably anticipated to contribute to visibility impairment in any mandatory Class I Federal area in another State or States, the State must consult with the other State(s) in order to develop coordinated emission management strategies. The State must consult with any other State having emissions that are reasonably anticipated to contribute to visibility impairment in any mandatory Class I Federal area within the State.²⁶

ADEQ has met this obligation to consult with Missouri in order to develop coordinated emission management strategies. The Regional Haze Regulations further stated that:

The State must document the technical basis, including modeling, monitoring and emissions information, on which the State is relying to determine its apportionment of emission reduction obligations necessary for achieving reasonable progress in each mandatory Class I Federal area it affects. The State

²⁵ 82 FR 3078- at 3080

²⁶ 40 CFR 51.308(d)(3)(ii)

may meet this requirement by relying on technical analyses developed by the regional planning organization and approved by all State participants.²⁷

In the 2008 Arkansas Regional Haze SIP, ADEQ relied upon the technical analyses developed by CENRAP and approved by all State participants. CENRAP visibility projections indicated that the emission reductions planned for CENRAP states were sufficient to achieve the reasonable progress goals for Class I areas located in Missouri Class I areas.²⁸ In addition, CENRAP contracted with Alpine Geophysics to evaluate control strategies for reasonable progress. Alpine Geophysics recommended reasonable progress control strategies for six Class I areas within the CENRAP region: Big Bend National Park, Breton Island, Boundary Waters, Guadalupe Mountains, Wichita Mountain, and Voyageurs.²⁹ Neither Hercules Glades nor Mingo were included in the list of regions for which additional control strategies were recommended for reasonable progress. In addition, no specific measures were requested by Missouri for achieving reasonable progress in each mandatory Class I Federal area affected by Arkansas.

With respect to EPA's request for voluntary remand without vacatur of the long-term strategy contained in their Nebraska FIP, ADEQ notes that EPA did not concede that the long-term strategy aspect of the Nebraska FIP was erroneous, but rather that EPA stated that they may not have fully explained their reasoning and that EPA may not have fully responded to comments raised during the comment period regarding this issue.³⁰ EPA also noted in their request for remand that EPA's "present explanation could potentially be construed in a manner that is inconsistent with EPA's interpretation of the relevant statutory and regulatory requirements."³¹ In the request for remand, EPA stated that they will provide stakeholders with notice and opportunity to comment if EPA determines that it is necessary to introduce new evidence into the records or change its final decision.³² To date, EPA has not introduced new evidence—subsequent to their request for remand—into the docket or proposed changes to their final decision regarding the long-term strategy of the Nebraska FIP.

ADEQ notes certain differences between the circumstances regarding reasonable progress determinations with respect to GGS and ADEQ's determination in the Proposed SIP. First, GGS was a subject-to-BART facility. EPA disapproved the long-term strategy for Nebraska's Regional Haze SIP to the extent that it relied on what EPA stated was a flawed BART determination for GGS.³³ EPA promulgated a FIP for Nebraska reliant on the Transport Rule as an alternative to BART for SO₂ and determined that no source-specific emission limit was

²⁷ 40 CFR 51.308(d)(3)(iii)

³¹ *Id.* at page 12

³² *Id.* at page 12

³³ 77 FR 40150

necessary for GGS.³⁴ ADEQ's determination in the Proposed SIP was made after consideration of particulate source apportionment data, visibility progress at Missouri's Class I areas in relation to their goals, BART controls contained in the Proposed SIP, control measures included in the 2008 AR RH SIP, and the 2007 NOx SIP revision. The CENRAP technical support documents further support ADEQ's determination that no additional controls at Arkansas sources are necessary to make reasonable progress at Missouri's Class I areas.

ADEQ will continue to consult with Missouri DNR on the development of any future Regional Haze SIP.

Response 3 addresses comments referring to the STi study funded by Sierra Club.

This comment does not necessitate changes to the Proposed SIP.

Comment 13:

One commenter advocated for community planning to reduce energy use.

Response 13:

ADEQ acknowledges the commenter's recommendation that community planning can be used to reduce energy use; however, city planning and zoning are not within the scope of ADEQ's regulatory authority.

This comment does not necessitate changes to the Proposed SIP.

Comment 14:

Some commenters opposed replacing the EPA FIP with the proposed SIP. These commenters asserted that the Proposed SIP is too weak. In particular, the commenters objected to replacing the requirements for White Bluff and Independence from the FIP with the requirements included in the Proposed SIP. One commenter requested that ADEQ put in place changes that will improve the air quality in our wild areas, as well as for the whole state. Other commenters recommended that ADEQ scrap the weak proposed plan and adopt the stronger plan that EPA wrote.

Response 14:

ADEQ disagrees with commenters that the Proposed SIP is too weak and that ADEQ should scrap the Proposed SIP in favor of EPA's FIP. The controls required in the Proposed SIP are consistent with Clean Air Act §169A, EPA's Regional Haze Regulations, and EPA's guidance for the first planning period. In comments on EPA's FIP and Arkansas's Petition for

³⁴ Id.

Reconsideration of the FIP, ADEQ raised objections with respect to controls required in the FIP for White Bluff and Independence.³⁵

In making control determinations for subject-to-BART facilities, ADEQ evaluated facility specific information in arriving at Proposed BART determinations in accordance with the five statutory BART factors and EPA regulations and guidance for the first planning period. ADEQ factored new information—which was not included in the FIP—regarding Entergy’s planned changes in coal-fired operations at White Bluff into its analysis and reasonably concluded that a different BART determination was appropriate and warranted.

In determining whether additional controls were necessary for reasonable progress, ADEQ examined the CENRAP particulate source apportionment data, visibility improvement progress, emissions relative to distance from Class I areas, and the four statutory reasonable progress factors.. Based on ADEQ’s assessment of the combined evidence of these evaluations, ADEQ determined that no additional controls beyond BART and existing programs are necessary to achieve reasonable progress during the first planning period. This determination is consistent with EPA guidance which instructs that it is reasonable for states to defer more expensive controls to later planning periods in order to maintain a consistent glide path toward the long-term goal.³⁶ ADEQ will reevaluate whether additional controls are necessary for maintaining reasonable progress for future planning period Regional Haze SIPs. SIPs for the next Regional Haze Planning Period are due in 2021.

Although this comment does not necessitate changes to the proposed SIP, ADEQ is revising the reasonable progress analysis to discuss additional factors described in other comments received as well as comments regarding whether LSC at Independence should be considered an existing control. See Responses 25(c) and (d).

Comment 15:

Some commenters expressed concern with ADEQ’s previous and current actions with respect to implementation of the Regional Haze Program in Arkansas. Commenters asserted that haze reduction in Arkansas is more than a decade overdue. These commenters attributed this delay in implementation to ADEQ’s actions. Specifically, the commenters argue that ADEQ submitted a deficient plan in 2008 which was then disapproved by EPA in 2012. The commenters allege that

³⁵ ADEQ (2015) Re: Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Docket No. EPA-R06-OAR-2015-0189

ADEQ (2017) Petition for Reconsideration and Request for Administrative Stay in re: Promulgations of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan Final Rule (Docket No. EPA-R06-OAR-2015-0189)

The objections raised in the aforementioned documents to EPA’s FIP are hereby incorporated by reference and included as Exhibits C and D to this Responsive Summary.

³⁶ EPA (2007) “Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program” at page 1-4

instead of submitting a revised plan, ADEQ affirmatively chose to do nothing. As a result, EPA issued a FIP which Arkansas has sued to block and has issued the proposed plan to replace. The commenters argue that implementation of the haze program would be well underway if not for ADEQ's decade of delay and obstruction.

Several commenters asserted that ADEQ could do a better job at protecting air quality. One commenter stated that the proposed plan contradicts ADEQ's mission to "protect, enhance, and restore the natural environment for the well-being of all Arkansans." The commenter asserted that the Department has repeatedly ignored the requests and desires of the people in its decisions on environmental regulations. Other commenters expressed similar sentiments and urged ADEQ to take action to now to protect the people the agency serves and to abide by Clean Air Act requirements for reducing haze. Commenters also urged ADEQ to think about future generations. Commenters requested that ADEQ strengthen protections against pollution through regulation. Commenters asserted that money ADEQ receives from the U.S. Environmental Protection Agency (EPA) and state tax dollars need to be allocated to doing more to reduce smog in our parks. Another commenter stated that ADEQ needs to take into account the highest quality of education and utilize that knowledge to make a future that can make a difference in the lives of all Arkansans.

One commenter stated that the people of Arkansas love our natural state, but that they also love having a job. The commenter stated that ADEQ is doing an increasingly better job at striking that difficult balance.

Response 15:

ADEQ acknowledges the commenters concerns regarding the timeliness of a complete SIP submittal and is working to expeditiously meet all Clean Air Act requirements regarding the regional haze program for the first planning period. Air quality in Arkansas has substantially improved in recent years. Arkansas is in attainment for all of the NAAQS and is well below both the Proposed SIP's and the EPA's 2018 regional haze reasonable progress goals for Caney Creek and Buffalo River Wilderness Areas. See Responses 1 and 3.

ADEQ disagrees that the Proposed SIP contradicts the Department's mission statement. The Proposed SIP includes measures necessary to ensure progress in improving visibility at Class I Areas in Arkansas. Arkansas is well below its 2018 goal and is projected to remain under the glide path until well into the second planning period.³⁷ This plan assures reasonable progress toward achieving background visibility conditions by 2064, which will ensure that future generations will benefit from the increasing visibility at affected Class I areas.

ADEQ held a public comment period as well as a public hearing in order to solicit input from the public into its decisions. ADEQ finds this input to be a valuable aid in making its decisions and

³⁷ See Responses 1 and 3; See also IMPROVE Data Statistical Analysis, Trinity Consultants (July 2015).

thanks the commenters for sharing their thoughts with the Department. ADEQ is making certain changes to the Proposed SIP in response to other comments received to further strengthen the plan. The SIP, including the revisions ADEQ has made in response to public comment, meets all applicable Clean Air Act and Regional Haze Program requirements.

ADEQ acknowledges the commenters' preferences to allocate greater funding to address visibility. However, the Proposed SIP does not allocate funding, but instead requires certain controls and retrofit technology to assure reasonable progress toward background visibility conditions by 2064.

ADEQ acknowledges the comment that ADEQ is doing an increasingly better job at striking an appropriate balance in its regulatory duties and thanks the commenter for this input.

This comment does not necessitate changes to the Proposed SIP.

Comment 16:

Some commenters asserted that low sulfur coal (LSC) was an existing control at White Bluff and Independence; whereas, Entergy asserted that ADEQ's conclusion that LSC is an existing control at White Bluff and Independence is inaccurate.

Commenters provided differing reasons about why they viewed LSC as an existing control. One commenter asserted that the main requirement for Entergy in the proposed SIP is to burn LSC, which the commenter stated Entergy is already doing. Commenters noted that maximum monthly emission rates for White Bluff and Entergy could be rounded down to the tenths place to show compliance with a 0.6 SO₂/MMBtu emission limit. Other commenters stated that LSC is an existing control based on sulfur content limits approved for White Bluff pursuant to the Arkansas Utility Facility Environmental and Economic Protection Act (Ark. Code Ann. § 23-18-501, *et seq.*). The commenters noted that average monthly emission rates were less than permitted emission rates.

Entergy explained in its comments that an emission limit of 0.6 lb SO₂/MMBtu based on LSC does not reflect existing controls. Entergy stated that ADEQ improperly compared emission rates on a monthly basis to a three-hour permit limit. Entergy asserted that longer term emission rates must be lower than the short-term three-hour limit due to the natural variability in the sulfur content of coal. Entergy noted that the maximum three-hour average emission rate at White Bluff from 2014–2016 was 1.1 lb SO₂/MMBtu even though the monthly averages were lower.

Response 16:

ADEQ notes that a 1974 APC&EC order issued pursuant to the Arkansas Utility Facility Environmental and Economic Protection Act stated that LSC should be used at White Bluff.^{38,39} However, Entergy is not currently required to comply with a 0.6 lb SO₂/MMBtu thirty-boiler-operating day average pursuant to that order. Current permitted emission limits for White Bluff under their ADEQ Title V permit are 1.2 lb SO₂/MMBtu on a three-hour average.

In the Proposed SIP, ADEQ noted that thirty-boiler operating day average SO₂ rates for White Bluff and Independence were frequently below 0.6 lb SO₂/MMBtu; whereas, permitted emission limits for the two facilities were 1.2 lb SO₂/MMBtu and 0.93 lb SO₂/MMBtu, respectively. ADEQ acknowledges that the data provided by Entergy in comments on the Proposed SIP indicate that lower long term rates, which were often below 0.6 lb SO₂/MMBtu, may be necessary to ensure compliance with the higher short term limits due to the natural variability of sulfur content in coals. Therefore, ADEQ concedes that it is reasonable to assume that an emission limit of 0.6 lb SO₂/MMBtu does not represent an existing control for either White Bluff or Independence. ADEQ also notes that Entergy estimates that a \$ 0.50/ton cost premium would be required to ensure that all coals have sulfur content below 0.6 lb SO₂/MMBtu. ADEQ will revise the SIP to clarify that such an emission rate is not based on an existing control at either White Bluff or Independence.

With respect to the commenters' assertion that emission rates greater than 0.6 lb SO₂/MMBtu could be rounded to the tenths place and show compliance, ADEQ will revise the SIP to indicate that any emission limit based on LSC is based on an emission limit of 0.60 lb SO₂/MMBtu because the assessments of this limit evaluated emission reductions based on this limit without rounding to the tenth's place.

Comment 17:

Some commenters expressed general support for the Proposed SIP. Some commenters stated that as proposed, the SIP is a very beneficial improvement over EPA's FIP.

³⁸ A description of Arkansas Power and Light's proposed use of low-sulfur Wyoming coal with an average sulfur content of 0.48% was included in the order for issuance of a certificate of environmental compatibility and public need. (Document Number 131 in Arkansas Public Service Commission Docket #73-048-U http://www.apscservices.info/EFilings/Docket_Search_Documents.asp?Docket=73-048-U&DocNumVal=131)

During 2016, White Bluff units used coal with average heat content per unit coal of 8518.754 Btu/lb coal based on monthly short tons of coal and MMBtu reported to the Energy Information Administration (EIA Form 923 <https://www.eia.gov/electricity/data/eia923/>). If the average sulfur content were assumed to be 0.48% as proposed by Arkansas Power and Light, the average monthly emission rate based on the heat content per unit coal would be 1.125 lb SO₂/MMBtu—assuming 100% conversion of the sulfur in the coal to SO₂ in the exhaust gas.

³⁹ Document Number 131 in Arkansas Public Service Commission Docket #73-048-U http://www.apscservices.info/EFilings/Docket_Search_Documents.asp?Docket=73-048-U&DocNumVal=131

Response 17:

ADEQ acknowledges and appreciates this comment. This comment does not necessitate changes to the Proposed SIP.

Comment 18:

Some commenters noted in the Proposed SIP language that should be revised to more accurately represent the age of subject facilities. Commenters recommended that ADEQ revise the language describing White Bluff as “installed in 1974” to say “in existence in 1974.” The commenters pointed out that the units were not commissioned until 1980 and 1981. Other commenters recommended that ADEQ should similarly revise the language describing Independence. The commenters noted that construction on Independence commenced in 1978 and commercial operation began in 1983 for unit 1 and 1984 for unit 2. Commenter requested that ADEQ remove any language that may indicate that the two Independence units are nearing the end of their remaining useful life. Specifically, the commenters requested that ADEQ remove the term “aging” on page 57 of the Proposed SIP. The commenters noted that the Independence units were designed to operate for sixty or more years if maintained properly and have several decades of remaining useful life.

Response 18:

ADEQ acknowledges the commenters recommendations for language revisions to more accurately characterize the age of the White Bluff and Independence facilities. ADEQ will revise the Proposed SIP accordingly.

Comment 19:

Some commenters asserted that ADEQ’s assessment of reasonable progress relied upon or utilized elements of EPA’s 2017 “Protection of Visibility: Amendments to Requirements of State Plans” (“2017 RHR Amendments”) and associated draft guidance. The commenters pointed out that the 2017 RHR Amendments are the subject of litigation and that EPA has recently published notice of its intent to reconsider certain aspects of the rule. Commenters asserted that it is appropriate to use the same regulations as EPA used in addressing the disapproved elements of the 2008 SIP. The commenters recommended that ADEQ avoid reliance on the 2017 RHR Amendments and associated draft guidance in the SIP and revise any portions of the Proposed SIP that rely upon the draft guidance and/or the challenged 2017 RHR Amendments.

Some commenters expressed concern with moving forward with the Proposed SIP now given the legal challenge to the 2017 RHR Amendments and EPA’s notice of intent to reconsider the rule. The commenters asserted that moving forward with the plan now will only result in a requirement to withdraw the SIP changes and redo the effort to conform to a revised rule. The

commenters noted that a “stop/start” approach is not likely to achieve results helpful to the Arkansas business community and the residents of Arkansas.

Response 19:

ADEQ disagrees with commenters’ assertions that ADEQ’s assessment of reasonable progress relied on, or utilized elements of, EPA’s 2017 RHR Amendments and associated draft guidance. As noted in Response 12, the preamble to the 2017 RHR Amendments explicitly stated that “EPA is making changes to the requirements that states [] have to meet for the second and subsequent implementation periods.”⁴⁰ ADEQ relied upon the requirements for the first planning period as promulgated in the 1999 “Regional Haze Regulations”⁴¹ and amended in the 2005 “Regional Haze Regulations and Guidelines for Best Available Retrofit (BART) Determinations”⁴² in the Proposed SIP.

ADEQ formulated the approach to evaluating whether additional controls were necessary for reasonable progress after consideration of key pollutants impacting visibility at Arkansas Class I areas, the 2007 “Guidance for Setting Reasonable Progress Goals under the Regional Haze Program,” and reasonable progress analyses performed for other states for the first planning period.⁴³ The Proposed SIP is consistent with this guidance and the Regional Haze Rule as codified in the first planning period. ADEQ agrees that it is appropriate to use the same regulations as EPA used in addressing the disapproved elements of the 2008 SIP. ADEQ did not rely on the 2017 RHR Amendments or associated draft guidance in constructing its reasonable progress assessment.

Because ADEQ did not rely on the 2017 RHR Amendments or associated draft guidance in constructing the Proposed SIP, the ongoing litigation and reconsideration surrounding the 2017 RHR Amendments is not germane to this proposal as the 2017 RHR Amendments provide changes that affect the second planning period and beyond only; whereas, the Proposed SIP addresses first planning period requirements. Therefore, there is no need to delay finalization of the Proposed SIP.

This comment does not necessitate changes to the Proposed SIP.

Comment 20:

ADEQ received several comments regarding the proposed BART analysis and emission limit determination for White Bluff. Some commenters suggested revisions were necessary to the analysis based on additional information provided by Entergy that was included in a notice of data availability issued by ADEQ on December 18, 2017 after proposal of the SIP. Some commenters stated that there were flaws in Entergy's analyses included in the notice of data availability and in the redacted version of Entergy's 2017 updated BART analysis for White Bluff that ADEQ used in its BART analysis and determination in the Proposed SIP. Some commenters asserted there were flaws in ADEQ's evaluation and proposed conclusions with respect to Entergy's 2017 updated BART analysis for White Bluff.

20(a):

Some commenters took issue with the remaining useful life assumptions for White Bluff included in the Proposed SIP based on a 2030 cessation of coal use date. Some commenters argue that ADEQ failed to utilize critically important facility-specific information provided by a Permittee regarding planned operating conditions of permitted facilities. In particular, Entergy submitted a document to ADEQ in which it stated that it has a planned cease-to-use-coal date for White Bluff for 2028 and that Entergy will take an enforceable restriction in that regard. The commenters alleged that ADEQ did not consider this key fact in developing its long-term strategy, including planned controls. The commenters urged ADEQ to revise its BART analysis to reflect Entergy's expectation that it will cease combusting coal at White Bluff on or before December 31, 2028. The commenters stated that neither statute nor the Regional Haze Regulations provide ADEQ with the authority to reassess and redefine the remaining useful life of a source. Other commenters stated that the remaining useful life assumptions used in the SIP are unlawful unless ADEQ adds a provision to the SIP that makes enforceable the requirement for White Bluff to cease burning coal or cease all operations by the date used in the remaining useful life analysis. Commenters asserted that the 2030 date assumed by ADEQ in the Proposed SIP has no support in the administrative record. Other commenters asserted that ADEQ's selection of a later date than contained in Entergy's updated five factor analysis is supported.

Response 20(a):

ADEQ acknowledges the commenters assertions regarding the December 31, 2028 date and agrees that, given Entergy's withdrawal of confidentially claims on their updated five factor analysis for White Bluff, it is appropriate to revise the SIP to reflect cessation of coal-fired operations by that date. On October 31, 2017, ADEQ proposed a December 31, 2030 cessation of coal-fired operations date based on a seven year remaining useful life for White Bluff and an assumed compliance date based on ADEQ's anticipation of the timeframe for approval of the final SIP by EPA. At that time, Entergy had provided ADEQ a copy of their updated BART analysis for White Bluff with certain information, including their proposed cessation of coal

dates, held confidential. Based on Entergy's assertion of confidentiality, ADEQ determined that it was not appropriate to disclose information held as a trade secret in the Proposed SIP. Therefore, ADEQ related the cost information provided by Entergy in the updated analysis to a previous letter from Entergy providing cost-effectiveness estimates for various remaining useful life assumptions.

Entergy's withdrawal of confidentiality claims on its updated five factor analysis substantively impacts ADEQ's assessment of the five BART factors.⁴⁴ Specifically, it alters ADEQ's evaluations with respect to compliance date assumptions and cessation of operations. ADEQ assumed a compliance date of 2023 based on five years after an anticipated 2018 approval of the SIP; however, Entergy's updated analysis used 2021 as an assumed compliance date. This coincides with the October 27, 2021 compliance date required by EPA's FIP. In addition, Entergy has now made public the proposal in the updated five factor BART analysis for White Bluff the 2028 cessation date; therefore, no back calculation based on the previous April 21, 2017 letter is necessary.

ADEQ will revise both the SIP narrative and administrative order to reflect the remaining useful life assumptions and a cessation of coal-fired operations by no later than December 31, 2028 consistent with Entergy's updated five factor analysis for White Bluff.

20(b):

Some commenters stated that ADEQ's BART analysis and determination should not be premised on any plan for early retirement or cessation of the use of coal at White Bluff during the next or any future planning period. The commenters asserted that such a requirement is outside the scope of the Proposed SIP because it would take place after the end of the first planning period. The commenters noted that BART guidelines and guidance do not require premature retirement or fuel switching. The commenters argued that the extent to which the Proposed SIP's BART determination for White Bluff is based on a premature retirement date that has not been approved, but would otherwise result in significant costs that would affect the continued viability of White Bluff before the end of its actual remaining useful life, is contrary to the intent of the Clean Air Act and BART guidelines. The commenters further asserted that early closure or cessation of coal-fired operations at White Bluff would require approval of other regulatory authorities. The commenters stated that any requirement to fuel switch or close is not practically or finally enforceable at this time and should not be included in the final Phase II SIP.

Response 20(b):

⁴⁴ Entergy's Updated Five Factor Analysis for White Bluff was public noticed as a notice of data availability (NODA) on December 21, 2017. ADEQ also extended the comment period on the SIP at that time to allow the public to consider Entergy's updated analysis as they developed comments on the Proposed SIP. This NODA and associated documents are included in Tab E of the final SIP.

ADEQ acknowledges that the BART guidelines and guidance do not require premature retirement or fuel switching as BART. However, both the guidelines and the guidance require ADEQ to consider the remaining useful life of the facility for which controls are being evaluated. The BART guidelines state that remaining useful life is the difference between “the date that controls will be in place” and “the date the facility permanently stops operations. Where this affects the BART determination, this date should be a federally- or State-enforceable restriction preventing further operation.”⁴⁵

Other states have included in their Regional Haze SIPs an enforceable requirement to cease operations by a date certain at the request of subject facilities.⁴⁶ For example, Oregon reopened their BART regulations at the request of PGE to include an alternative to BART for PGE Boardman in which PGE would commit to cease burning coal at PGE Boardman by December 31, 2020.⁴⁷ Pursuant to this request, Oregon Department of Environmental Quality (ODEQ) performed an updated BART analysis based on a shorter remaining useful life for PGE Boardman and determined that their previous BART determinations for SO₂ of semi-dry flue gas desulfurization was not cost-effective based on the revised remaining useful life.⁴⁸ EPA approved ODEQ’s revised BART determination for PGE Boardman.⁴⁹ PGE’s operation cessation date for PGE Boardman was rendered enforceable through a revision to Oregon’s BART regulations at OAR 340-223-030(1)(e). Similarly, ADEQ is revising its disapproved 2008 BART determination for White Bluff—which was based on Dry FGD—to LSC after consideration of the revised remaining useful life of White Bluff as indicated by Entergy’s proposed commitment to cease coal-fired operations at White Bluff. Cessation of coal-fired operations will be rendered enforceable via a final, signed administrative order that will be submitted with the final SIP.

This comment does not necessitate changes to the Proposed SIP.

20(c):

Some commenters took issue with ADEQ’s proposed compliance date assumptions included in cost-effectiveness calculations for retrofit technologies at White Bluff in the Proposed SIP. One commenter stated that it is arbitrary to use a 2023 compliance date for Dry FGD in determining remaining useful life because Entergy is already required to comply with an emission limit for Dry FGD by October 27, 2021 by EPA’s FIP. The commenters noted that EPA has not reconsidered or stayed this requirement and that the court has also not stayed this requirement. The commenters further explain that Entergy should have been planning for the installation of Dry FGD since at least 2013 when Entergy proposed such controls to ADEQ and EPA to meet

⁴⁵ (70 FR 39104- at 39169)

⁴⁶ Oregon (76 FR 12561), Washington (77 FR 72742), Oklahoma (79 FR 12944)

⁴⁷ 76 FR 12561

⁴⁸ Id.

⁴⁹ 76 FR 38997

BART requirements. In addition, the commenters noted that Dry FGD has been installed at other similar facilities in less than five years. The commenters stated that it was appropriate for Entergy to assume in its updated five factor analysis for White Bluff a 2021 compliance date for Dry FGD and a 2019 compliance date for DSI based on the timing of installation at other units.

Commenters disagreed on the amortization period based on the cessation of coal-fired operations date included in the SIP, the cessation date proposed by Entergy, and the assumed compliance date. One commenter suggested that ADEQ's calculated costs under the proposed compliance date assumptions would be greater if they were based on Entergy's anticipated cease to use coal date of 2028 because it would yield a five-year amortization period for installation of Dry FGD at White Bluff. Another commenter stated that Entergy's updated BART analysis for White Bluff should have used a 7.17 year remaining useful life for Dry FGD and a 9.17 year remaining useful life for DSI given their proposal to cease coal-fired operations by December 31, 2028 and an assumed compliance date of October 27, 2021 for Dry FGD based on the FIP.

Response 20(c):

ADEQ is revising its compliance date assumptions to reflect the assumed compliance dates for controls at White Bluff used in the now publicly available updated five-factor analysis for White Bluff. See Response 20(a). ADEQ also notes that compliance dates for Dry FGD at White Bluff in the FIP were stayed by the Eighth Circuit Court of Appeals on March 7, 2018.⁵⁰

ADEQ acknowledges that the FIP compliance date for Dry FGD is October 27, 2021; therefore, a remaining useful life based on this date rounded to the second decimal place would be 7.17 years (seven years and two months). It should be noted that Table A.2 in Appendix A to Chapter 2 of the EPA Control Cost Manual includes capital recovery factors on a yearly basis.⁵¹ ADEQ estimates that the average cost-effectiveness of Dry FGD based on 7.17 years of remaining useful life and the cost information provide by Entergy in Table 4-4 of the updated White Bluff BART analysis would be \$5,331/ton for White Bluff Unit 1 and \$5,298/ton for White Bluff Unit 2.⁵² This rounding difference would not put the cost-effectiveness for Dry FGD at White Bluff within the range typically found cost-effective and does not alter ADEQ's determination.

ADEQ disagrees with the commenter that asserts that remaining useful life assumptions for DSI should be based on 9.17 years. There is nothing in the record to support such an assertion. The commenter agreed that Entergy's assumption that DSI could be installed and operating by the end of 2019 was appropriate; therefore, the remaining useful life for DSI would be nine years, not 9.17 years.

⁵⁰ Appellate Case : 16-4270 Entry ID: 4636668

⁵¹ Annualized Capital Cost = Capital Costs x Cost Recovery Factor. Cost-Recovery Factor for 7.17 years = 0.182115

⁵² Cost-effectiveness values included in approved SIPs and FIPs for BART are typically below \$5,000/ton. This is illustrated in Exhibit B to the National Parks Conservation Association, Earthjustice, and Sierra Club comments on the Proposed SIP.

20(d):

One commenter asserted that the emission reduction and cost-effectiveness calculations in Entergy's 2017 updated five-factor analysis for White Bluff that ADEQ relied upon in the Proposed SIP were flawed. In particular, the commenter disagreed with Entergy's change in baseline period, approach to calculating emission reductions from LSC, approach to calculating emission reductions from dry sorbent injection (fifty percent control and eighty percent control), and cost-effectiveness calculations.

i. Baseline Period

The commenter objected to certain baseline assumptions Entergy included in its 2017 updated BART analysis for White Bluff. The commenter stated that there was no basis provided by Entergy for the use of a 2009–2013 baseline for evaluating SO₂ controls rather than a 2001–2003 baseline. The commenters further argue that use of a 2001–2003 baseline is necessary because the annual average SO₂ emission rate for the more recent baseline period is below the assumed controlled emission rate for LSC of 0.60 lb SO₂/MMBtu used in the cost-effectiveness calculations. The commenter also questioned why Entergy's proposed emission limits for DSI were based on 2014–2016 data when Entergy used a 2009–2013 baseline for costs. The commenter also questioned Entergy's use of the updated baseline for visibility impact modeling and stated that Entergy did not provide any basis for deviating from the 2001–2003 baseline for SO₂ emissions for its BART visibility modeling. The commenter also supported their questioning of the baseline change with the following quote by EPA from their July 1, 1999 action:

After considering public comments on the baseline issue, EPA has determined that the most appropriate "baseline period" would be a fixed, 5-year period extending from calendar year 2000 through calendar year 2004. The EPA concluded that a standard baseline period provides for greater national consistency in establishing this important value, and therefore, is preferable to a provision allowing the baseline period to be a variable number of years. Using a common number of years and data points to calculate the baseline value for each site is consistent with fundamental statistical principles and will provide for easy comparison of data from multiple sites as the program is implemented.⁵³

ii. Alternative Cost-Effectiveness Calculation Methodology

The commenter objected to Entergy's approach to calculating cost-effectiveness for LSC. The commenter points out that this method deviates from the BART guidelines and argues that the approach improperly inflates the cost-effectiveness value of LSC. The commenter asserts that the cost-effectiveness for LSC should be zero if using a baseline of 2009–2013 based on annual average emissions at White Bluff. The commenter further argues that comparing cost-

⁵³ 64 FR 35729

effectiveness for add-on controls calculated according to the BART guidelines with cost-effectiveness for LSC calculated according to the alternative methodology is not an “apples-to-apples” comparison. The commenter states that ADEQ must ensure that cost-effectiveness and incremental cost-effectiveness analysis for all controls are evaluated based on the same methodology for calculating annualized cost of control and annualized emission reductions.

iii. Control Efficiency Design Assumptions

The commenter asserted that the costs of DSI included in Entergy’s 2017 updated BART analysis for White Bluff were overstated. The commenter argued that the design and cost of controls should be based on the average annual reductions in SO₂ emission rate, not the highest five percent of SO₂ emissions over the baseline period. In addition, the commenter asserts that the proposed emission limits evaluated are based on a lower percentage of control than assumed for cost. The commenter also questioned the assumptions that upgrades to Entergy’s existing electrostatic precipitator, which is factored into the cost of controls, would be necessary. The commenter points out that their assessment of White Bluff’s historic particulate loading based on Energy Information Administration Data, is less than assumed for the inlet ash loading to the electrostatic precipitator (ESP) in the evaluation by Fuel Tech included with the updated BART analysis of whether upgrades to the ESP are necessary to accommodate the additional particulate loading from DSI. The commenter also stated that the assumed outlet particulate matter (PM) emission rate included in Fuel Tech’s analysis were lower than permitted limits and is not supported by stack test data.

iv. Overnight Costing Methodology

The commenter also stated that it is unclear whether the cost-effectiveness numbers relied upon by ADEQ comport with the overnight costing methodology of EPA’s Control Cost Manual. In Entergy’s 2017 updated BART analysis for White Bluff, Entergy two cost-effectiveness tables, one based on Entergy’s assessment of actual costs and one adjusted for EPA-exclusions. The commenter noted that ADEQ utilized in the proposed SIP the cost-effectiveness values adjusted for EPA-exclusions, yet did not explicitly state this. The commenter states that it is unclear whether all other costs not consistent with EPA costing methodology, besides AFUDC, were excluded.

v. Alternative Integrated Planning Model Cost Modules-Based Cost-Effectiveness Calculations

The commenter provided revised calculations of the cost-effectiveness of DSI and Dry FGD at White Bluff based on their own assessment of costs for these retrofits. For these calculations, the commenter revised assumptions for remaining useful life, baseline, and costs. The commenter calculated cost-effectiveness values for 11, 9.17, 7.17, and 5 years of remaining useful life. The commenter revised cost of controls to be based upon Integrated Planning Model (IPM) cost modules. The commenter asserted that based on their calculations, DSI and Dry FGD would be cost-effective at any of the remaining useful life values evaluated.

Response 20(d):

i. Baseline Period

For the Entergy White Bluff cost effectiveness analyses, ADEQ used the SO₂ baseline period of 2009–2013. One commenter stated that the original baseline period of 2001–2003 was a more appropriate baseline period and that using the 2001–2003 baseline period “is most consistent with the baseline period that EPA has stated is to be used for baseline visibility conditions in EPA’s regional haze rules.” ADEQ disagrees with this assertion. At the request of ADEQ, Entergy provided an updated BART five-factor SO₂ analysis for White Bluff (dated August 18, 2017) to supplement previous BART analyses (dated February 2013, October 2013, August 2015, and August 2016) submitted to EPA for their consideration in development of the AR RH FIP. Among the specific updates incorporated into Entergy’s August 18, 2017 BART analyses, Entergy updated the original 2001–2003 SO₂ baseline period (36,723 tons per year (tpy) average) to 2009–2013 (31,972 tpy average) for consistency because in EPA’s development of the AR RH FIP⁵⁴, EPA also had revised White Bluff’s Unit 1 and Unit 2 baseline emissions by using both NO_x and SO₂ (EPA calculations as part of a response to comments received on the draft FIP) emissions from the five year period of 2009–2013 and excluded the maximum and minimum years.

With regard to the commenter’s questioning of why Entergy’s proposed emission limits for DSI was based on 2014–2016 data when Entergy used a 2009–2013 baseline for costs, ADEQ re-reviewed the DSI Cost Report and asked Entergy to also review this document again. Subsequent to ADEQ’s request to Entergy, Entergy provided ADEQ with a response indicating that the 2014–2016 reference in the Sargent & Lundy Cost Report was a typographical error: the 0.66 lb SO₂/MMBtu thirty-day average was, in fact, calculated from 2009–2013 SO₂ emissions, and Entergy also provided to ADEQ a revised Cost Report that corrects the typographical error.⁵⁵

Entergy’s modeled visibility improvement from evaluated SO₂ controls were based on an updated baseline of 2009–2013 emissions rather than the 2001–2003 baseline emissions EPA used in the AR RH FIP to project visibility improvements from Dry FGD and Wet FGD. This change in baseline emissions impacts the modeled visibility benefit from Dry FGD. The modeled visibility benefit of Dry FGD at each unit is fifteen to twenty-six percent lower in Entergy’s updated analysis than estimated in the AR RH FIP. EPA did not evaluate visibility improvements associated with DSI, enhanced DSI, and LSC in the AR RH FIP; however, ADEQ expects that the relative difference in cost-per-deciview among the control options evaluated would be similar across both baseline emissions periods. The difference in visibility impact estimates due to differences in estimated baseline emissions between the AR RH FIP and Entergy’s updated five factor analysis does not change ADEQ’s ultimate decision for its SO₂ BART determination for White Bluff, which is based on an assessment of all five statutory BART factors.

⁵⁴ From the EPA-RO6-OAR-2015-0189-0205 docket “White Bluff_R6 cost revisions2-revised” at Regulations.gov

⁵⁵ The revised Cost Report has been included in Appendix D of the final SIP.

ADEQ finds that the commenter took the July 1, 1999 EPA quote out of context.⁵⁶ The quote provided by the commenter described EPA's determination with respect to the five-year baseline period used for the tracking of progress for each Class I area, using monitor data, toward the goal of obtaining natural conditions. This quote is not associated with a three-year baseline period to be used for visibility impact modeling.⁵⁷

ii. Alternative Cost-Effectiveness Calculation Methodology

ADEQ disagrees with the commenters' assertions that the cost-effectiveness of LSC should be zero for White Bluff. If the traditional approach of using annual emission reductions were used, as opposed to the maximum thirty-day emissions rate, the cost-effectiveness value would near infinity. This would not provide a meaningful framework for comparison since there would be low cost emission reductions as a result of compliance with a 0.6 lb SO₂/MMBtu emission rate at White Bluff.

iii. Control Efficiency Design Assumptions

At the request of ADEQ, Entergy provided an updated BART five-factor SO₂ analysis for White Bluff (dated August 18, 2017) that included cost estimates based on design parameters that were developed by Sargent & Lundy. Sargent & Lundy used an SO₂ inlet rate of 0.76 lb SO₂/MMBtu, which was the highest five percent of SO₂ emissions for the baseline period of 2009–2013 (see our separate response to a commenters assertion that 2009–2013 is an inappropriate baseline period) and based their size and cost calculations on this emission rate.

Because control systems are designed based on reasonable estimates of maximum potential emissions, ADEQ finds that Sargent & Lundy's design of the DSI control system based on an inlet SO₂ rate of 0.76 lb SO₂/MMBtu, which was calculated from the highest five percent of SO₂ emissions during the baseline period of 2009–2013, is appropriate. Otherwise, sizing control systems based on average conditions, as the commenter suggests, would result in undersized and inadequate control equipment during times when the actual emissions are greater than the average emissions.

Increases in PM loading to ESPs require additional control of PM emissions and as the commenter acknowledged: "Entergy would want to ensure that actual PM emissions do not increase above PSD significance levels and trigger PSD permitting." Upgrades to the ESP PM ash handling system should be sized based on an estimate of the maximum SO₂ inlet rate and not by calculating ash loading using EPA's AP-42 emission factors, which can result in undersizing the control equipment. Furthermore, in their analysis the commenter also referenced stack test data results of controlled PM emission rates of 0.019 and 0.016 lb/MMBtu for the two units and Sargent & Lundy estimated a controlled PM emission rate of 0.0155 lb/MMBtu based on a

⁵⁶ 64 FR 35728.

⁵⁷ See 64 Fed. Reg. 35728 and the "Guidance for Tracking Progress Under the Regional Haze Rule", Section 1.5, Page 1-4 (<https://www3.epa.gov/ttnamti1/files/ambient/visible/tracking.pdf>)

modeling simulation. Based on the stack test data and Sargent & Lundy's modeling, ADEQ finds that a design target of 0.015 lb/MMBtu is reasonable and that upgrades to the ESP are not an "unrealistic" component of the evaluated DSI project.

iv. Overnight Costing Methodology

EPA's BART Guidelines suggest, when possible, that cost estimates should be based on EPA's Control Cost Manual, which describes a cost-estimating methodology. From Entergy's August 17, 2017 updated BART analysis that included Cost Basis Reports prepared by Sargent & Lundy for White Bluff, ADEQ understands that Sargent & Lundy did prepare cost estimates for White Bluff using the BART Guidelines and the Control Cost Manual methodology in addition to cost-estimates relied upon based on Entergy's claimed actual costs. Therefore, ADEQ's evaluation of costs based on the information contained in Table 4-4 of Entergy's updated White Bluff BART analysis does conform to EPA costing methodology requirements. Entergy's cost estimates in Table 4-4 did not include "Allowance for Funds Used During Construction" and "Owner's Costs."

v. Alternative Integrated Planning Model Cost Modules-Based Cost-Effectiveness Calculations

While the IPM cost modules do provide BART control technology unit-specific costs, using IPM's cost modules solely with information from publicly available sources does have unit-specific limitations and should be used with caution when more appropriate and detailed site-specific information is available. IPM was developed to provide generic costs to allow "in the ballpark" comparisons of various control technologies and not to be relied on for unit-specific costs when more appropriate unit-specific and site-specific information is available and was not intended to be used as a substitute for otherwise known site-specific cost information. See Sargent & Lundy's comments for an additional discussion of the IPM model and using the *Chemical Engineering Plant Cost Index* (CEPCI) to adjust IPM-generated costs. This comment does not necessitate changes to the Proposed SIP.⁵⁸

20(e):

ADEQ received some comments affirming and some comments disagreeing with ADEQ's cost-effectiveness determinations for retrofit technology at White Bluff. Some commenters disagreed with ADEQ's assessment of cost-effectiveness for Dry FGD and DSI. Other commenters agreed with ADEQ's determination that in light of remaining useful life (seven years for Dry FGD and nine years for DSI) for White Bluff, DSI and Dry FGD are not cost-effective.

⁵⁸ Sargent & Lundy Comments on the Conservation Organization's Technical Support Document Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas State Implementation Plan Regional Haze SIP for 2008–2018 Planning Period Prepared by Victoria R. Stamper, February 1, 2018 (included as Exhibit F to this Responsive Summary)

One commenter asserted that ADEQ had inaccurately calculated the average dollar per deciview values in Table 4. Specifically, the commenter alleged that ADEQ had included the annualized cost for LSC in its annualized costs for DSI, enhanced DSI, and Dry FGD. The commenter stated that ADEQ assumed LSC would be implemented in addition to the other assess controls.

Some commenters stated that, because there is no enforceable requirement for White Bluff Units 1 and 2 to cease burning coal or cease all operations by a date certain, a thirty-year remaining useful life is more appropriate for assessing control options at White Bluff. The commenters stated that the resulting cost-effectiveness of Dry FGD \$2,565/ton for unit 1 and \$2,421/ ton for unit 2 are well within the range of costs that EPA and other states have typically found cost-effective. The commenters noted that ADEQ did not specify a threshold for considering controls cost-effective. The commenters further explained that, based on their revised calculations, Dry FGD and DSI would be cost-effective even with a five, seven, or nine year remaining useful life. The commenter notes that Dry FGD would improve visibility more than DSI or LSC. Commenters stated that it is EPA's policy that control costs incurred at similar sources to meet BART or regional haze control requirements should not be considered unreasonable.

Response 20(e):

ADEQ disagrees with the commenters that the annualized costs for DSI, enhanced DSI, and Dry FGD used to calculate the values in Table 4 included the annualized cost of LSC. ADEQ did not assume that LSC would be implemented in addition to the other assessed controls. The White Bluff Cost Calculations Datasheet provided with the Proposed SIP includes formulas that demonstrate ADEQ's calculations in translating the incremental cost-effectiveness values provided in Table 4-4 of the updated White Bluff five factor analysis. The formulas back-calculate the incremental annualized costs for DSI, Enhanced DSI and Dry FGD from incremental cost-effectiveness relative to LSC and incremental emission reductions relative to LSC. Incremental annualized costs are the difference in costs between two control technologies. Below is an example formula for calculating the incremental annualized cost of DSI relative to LSC.

Formula 1:

$$\begin{aligned} & \textit{Incremental Annualized Cost of DSI relative to LSC} \\ & = (\textit{Annualized Cost of DSI}) - (\textit{Annualized Cost of LSC}) \end{aligned}$$

The formula below shows how the incremental annualized cost of DSI was back-calculated from the information that was not redacted in Table 4-4 of the updated White Bluff analysis.

Formula 2:

Incremental Annualized Cost of DSI

$$= (\text{Incremental Cost-effectiveness of DSI vs LSC}) \times (\Delta \text{Emissions DSI} - \Delta \text{Emissions LSC})$$

To calculate the actual annualized cost from the incremental cost of DSI relative to LSC, one must add the LSC to the incremental cost of DSI. This is a simple rearrangement of Formula 1. Therefore, the commenter is incorrect in their statement that ADEQ mischaracterized the annualized costs for DSI, Enhanced DSI, and Dry FGD at White Bluff.

Although ADEQ's back calculated values were accurate for the assumptions upon which they were premised, ADEQ is revising its evaluation of costs for White Bluff based on the costs included in Entergy's updated five-factor analysis for White Bluff. ADEQ did not rely on Entergy's values in the Proposed SIP because Entergy had specifically redacted the values and requested that they be considered a trade secret when they originally submitted the analysis on August 18, 2017. Entergy has since withdrawn confidentiality claims with respect to their cost calculations. Therefore, it is now appropriate to use those values included in Table 4-4 of Entergy's updated five factor analysis for White Bluff, which are based on allowed costs under EPA's control cost methodology.

ADEQ disagrees with those commenters that state that ADEQ should base cost-effectiveness calculations for White Bluff on a thirty-year remaining useful life. ADEQ included in the proposed SIP an AO including Entergy's proposed cessation-of-coal-fired-operations date for White Bluff; therefore, truncation of the remaining useful life assumed for cost-effectiveness calculations is consistent with the BART guidelines. The cessation of operations date will be rendered enforceable through administrative order.

ADEQ also disagrees with the commenters assertions that Dry FGD is cost-effective given five or seven years remaining useful. Specifically, ADEQ disagrees with the commenters' calculations, which improperly rely upon generic IPM cost data when facility-specific data is available. ADEQ also finds that Entergy's use of a more recent baseline for evaluating emission reductions is reasonable. See Response 20(d).

ADEQ acknowledges that in assessing BART controls, the control costs incurred at similarly situated sources to meet BART are relevant in determining whether a control is cost-effective. Given a seven year remaining useful life, the Dry FGD at White Bluff is not within the range typically found cost-effective for BART. In the Regional Haze FIP for Montana, EPA rejected lime spray drying as BART because EPA determined that at \$5,442/ton, the control was not cost-effective. Therefore, ADEQ's rejection of Dry FGD as a BART based on an average cost-effectiveness of \$5,403/ton has precedent. ADEQ also notes that all of the cost-effectiveness values for BART included Exhibit B to comments on the Proposed SIP submitted by the National Parks Conservation Association, Earthjustice, and Sierra Club are below \$5,000.

This comment does not necessitate changes to the Proposed SIP.

20(f):

Some commenters noted concerns with ADEQ's evaluation of visibility anticipated from retrofit technology controls at White Bluff that were assessed in Entergy's 2017 updated BART analysis.

Some commenters noted that cost of control is only one of the five factors that must be considered at arriving at a BART determination and that an over-reliance on cost-effectiveness calculations based on an arbitrary remaining useful life does not properly take into account or give proper effect to the other BART factors. The commenters noted that the Entergy's modeling demonstrates that the difference in visibility improvement anticipated from LSC versus the most stringent technology is less than 0.5 deciviews. The commenters further pointed out their ongoing concerns regarding modeling bias of the CALPUFF model. The commenters noted that previous CALPUFF modeling has produced modeled visibility impacts greater than CAMx modeling. The commenters argued that the overall visibility improvement from the use of control technologies at White Bluff, as well as the differences in control technologies, is negligible.

Other commenters asserted that Entergy's approach to modeling LSC in the 2017 updated BART analysis for White Bluff does not follow the approach outlined by EPA. The commenter asserts that Entergy's projection of the maximum hourly SO₂ rate for LSC resulted in a much lower emission rate than a properly calculated maximum hourly rate based on a 2009–2013 baseline. The commenters stated that the maximum daily pound per hour SO₂ emission rates should have been calculated based on maximum daily pound per hour rates over the baseline rather than based on maximum permitted heat input capacity. The commenter asserted that this deviation assumes that White Bluff will not emit SO₂ at daily emission rates any higher than what the proposed BART limit would require on a thirty-boiler-operating day average. The commenters further noted that the form of the emission limit of 0.6 lb SO₂/MMBtu could result in a smaller reduction than assumed because SO₂ emission rates as high as 0.64 lb SO₂/MMBtu could be rounded down to 0.6 lb SO₂/MMBtu. The commenters provided their own estimates of visibility improvement from LSC by scaling Entergy's projections based on the ratio of the reduction from baseline emissions using their projected maximum daily rate to Entergy's projected reduction in maximum daily emission rates.

Response 20(f):

With regard to Entergy's August 17, 2017 updated five factor analysis for White Bluff, one commenter discusses the reliabilities of the CALPUFF and CAMx models and concludes that LSC is justified as BART. ADEQ recognizes the inherent assumptions associated with the use of predictive models and that these assumptions can differ by specific models. ADEQ thanks the commenter for their input.

ADEQ will clarify in the final SIP that the emission rate for LSC is based on an emission limit of 0.60 lb SO₂/MMBtu. This limit will preclude the rounding down of values higher than 0.6 lb SO₂/MMBtu to show compliance. This clarification is necessary because all cost, emission

reduction, and visibility improvement assumptions were based on an emission limit equal to 0.6 lb SO₂/MMBtu.

ADEQ disagrees with the commenter's assertions that the revised modeling analysis included in Entergy's August 17, 2017 BART Update that was based on baseline emissions from 2009–2013 should have been based on emissions from the original baseline period of 2001–2003 and also that Entergy's revised modeling analysis "overstated the visibility benefits of [LSC]". See Response 20(d)(i).

It appears that this commenter may be confusing the "consistency" rationale of use of a baseline period to determine BART controls with the necessary consistent use of a baseline period to establish baseline visibility conditions that determine the glide path associated with reasonable progress.

The commenter incorrectly states that "[i]n its previous BART modeling which EPA relied on in issuing its FIP, Entergy relied on 2001–2003 emissions for baseline SO₂ emissions." While it is correct that for the FIP, Entergy submitted information using the original baseline period for SO₂, in the final AR RH FIP and based on comments received, the EPA updated calculations for Entergy's White Bluff based on a SO₂ baseline emissions period to 2009–2013 and excluded the maximum and minimum years⁵⁹.

ADEQ finds that Entergy's use of an updated SO₂ baseline period of 2009–2013 to evaluate BART controls is appropriate.

20(g):

Some commenters supported ADEQ's determination that would establish a SO₂ BART emission limit for White Bluff units 1 and 2 of 0.6 lb SO₂/MMBtu, calculated as a thirty-day rolling average over each boiler operating day, based on LSC. Some commenters stated that this determination was supported even without taking into account Entergy's proposed retirement date or cessation of use of coal date.

Other commenters asserted that the BART determination for White Bluff should be Dry FGD. The commenters argued that ADEQ's proposed BART determination for White Bluff is inconsistent with its BART finding for Flint Creek. The commenters stated that Dry FGD and enhanced DSI are within the cost-effective range and would achieve visibility benefits when considering a remaining useful life of five, seven, nine, or eleven years. The commenters stated that under any BART analysis in which the remaining useful life is five years or greater, SO₂ BART for White Bluff is an emission limit of 0.06 lb SO₂/MMBtu. Some commenters stated that if ADEQ does not adopt a clearly enforceable deadline for White Bluff units to cease firing

⁵⁹ From the EPA-RO6-OAR-2015-0189-0205 docket "White Bluff_R6 cost revisions2-revised" at Regulations.gov

coal by December 31, 2028, then installation of Dry FGD is warranted. Commenters stated that if ADEQ does not determine SO₂ BART to be Dry FGD, then SO₂ BART for White Bluff must, at a minimum be based on the use of DSI.

Response 20(g):

After consideration of the comments, ADEQ's evaluation of the BART factors yields the same conclusion as was proposed in the Proposed SIP that BART for White Bluff units 1 and 2 should be based on LSC; however, ADEQ will clarify in the final SIP that the emission rate for LSC is based on an emission limit of 0.60 lb SO₂/MMBtu. ADEQ acknowledges that certain commenters would support this determination even without taking into account Entergy's proposed retirement date or cessation of the use of coal date. See Response 20(f).

ADEQ disagrees with those commenters that Dry FGD is cost-effective for a remaining useful life of seven years. Based on facility specific cost-information, neither Dry FGD nor either DSI option are cost-effective for the given remaining useful life assumptions included in the updated five factor analysis for White Bluff.

ADEQ's analysis regarding the proposed BART determination for Entergy White Bluff is consistent with ADEQ's BART finding with respect to SWEPCO's Flint Creek. Flint Creek has no enforceable cessation of operations date and did not request that ADEQ include such a requirement in the SIP. Therefore, the amortization period for installation of Dry FGD at Flint Creek is based on the thirty year life of the Dry FGD equipment because the remaining useful life of Flint Creek is anticipated to be at least as long as the capital recovery period for the Dry FGD equipment. In contrast, Entergy proposed that ADEQ include in the SIP an enforceable requirement for cessation of operations at White Bluff by the end of 2028. Therefore, the amortization of Dry FGD for White Bluff units was based on seven years of remaining useful life and Dry FGD was found not to be cost-effective.

20(h):

Some commenters supported ADEQ's proposal that Entergy be allowed three years after EPA's approval of the SIP revision to meet BART is LSC at White Bluff while others stated that three years was inconsistent with the record and the Clean Air Act.

In comments on the Proposed SIP, Entergy agreed with ADEQ that a three year timeline is reasonable for compliance with a BART limit based on LSC to ensure that sufficient time is provided to ensure that all contracted coal supply at White Bluff meets the SO₂ BART limit. Entergy stated that it is their practice to project how much coal will be needed in future years and to contract for a portion of the coal supply up to three years in advance. Entergy noted that they had a requirement to keep a reserve supply of coal at White Bluff to ensure that units can operate in the event of fuel disruption supply. Entergy stated that a three year timeline complies with the Regional Haze Regulations, which allow up to five years for compliance with BART.

Other commenters stated that ADEQ cannot allow Entergy three more years to comply with an emission limit that it is already capable of achieving. The commenters referred to EPA guidance stating that the time necessary for compliance should generally be considered on a source-by-source basis, with “each source required to comply by the soonest date that can be considered reasonable.”⁶⁰ The commenters stated that “as expeditiously as practicable” for the purposes of installing BART should meet the same standard as its meaning in EPA’s reasonable available control measures guidance. The commenters posited that ADEQ cannot rely on Entergy’s assertion about their contracting practices because no specific technical or economic evidence in the record supports Entergy’s assertion that more time is necessary to meet an emission limit based on LSC. The commenter indicated that nothing in the record demonstrates that it would be impracticable to meet a thirty-day rolling average of 0.6 lb SO₂/MMBtu right now. The commenter stated that neither Entergy nor ADEQ considered alternatives to extending the compliance deadline by three years. Specifically, the purchase of fuel blending equipment or longer averaging times were not considered. The commenter also stated that the Proposed SIP implies that Entergy has the technical ability to blend its coal supply because the company has been purchasing and using lower-sulfur coal for several years.

Response 20(h):

ADEQ disagrees with the commenter’s assertion that a three year compliance time frame with emission limit of 0.6 lb SO₂/MMBtu based on LSC for White Bluff is inconsistent with the record and the Clean Air Act. ADEQ’s understanding is that guaranteed compliance with such an emission rate cannot be achieved with Entergy’s existing fuel stocks at White Bluff and those for which Entergy has already contracted. As such, ADEQ determined that a three year compliance time frame was reasonable and appropriate.

In response to the comment, ADEQ requested additional documentation regarding the time necessary for compliance with an emission limit of 0.6 lb SO₂/MMBtu based on LSC for White Bluff. On April 3, 2018, Entergy submitted a letter providing further detail on the information described in the Proposed SIP regarding coal contracts for White Bluff, reserve supply requirements, and fuel blending capabilities.⁶¹ In particular, the letter further explains why the existing stocks and contracts limit Entergy’s ability to guarantee compliance with a 0.6 lb SO₂/MMBtu thirty-boiler operating day emission limit even after consideration of the limited fuel blending capability at White Bluff. ADEQ finds that the additional information provided by Entergy supports ADEQ’s proposed determination that three years for compliance with a 0.6 lb SO₂/MMBtu based on fuel switching to lower sulfur coal is as expeditious as practicable.

This comment does not necessitate changes to the Proposed SIP.

⁶⁰ EPA, Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period at 114 (July 2016)

⁶¹ Entergy’s April 3, 2018 letter is included as Exhibit G to this Responsive Summary.

Comment 21:

In comments on the Proposed SIP, SWEPCO expressed appreciation for ADEQ's willingness to consider all of the technical information submitted to EPA in support of the BART determination made for Flint Creek for SO₂. SWEPCO stated that the information amply supports ADEQ's determination that the equipment already installed at Flint Creek satisfies the requirements of the Regional Haze Program at this facility and that achieving an emission rate of 0.06 lb SO₂/MMBTU will reduce visibility impacts at Class I areas.

Response 21:

ADEQ acknowledges and appreciates this comment. This comment does not necessitate changes to the Proposed SIP.

Comment 22:

Some commenters asserted that ADEQ's proposed reasonable progress analysis is unnecessary and in conflict with positions taken by ADEQ and the State of Arkansas in comments on the FIP, ADEQ's Petition for Reconsideration, and the State of Arkansas's Petition for Judicial Review and arguments.

The commenters argued that a reasonable progress analysis is not required because Arkansas is already meeting its reasonable progress goals for the first planning period and the two Class I areas are below the glide path. The commenters noted that EPA's 2007 guidance on reasonable progress for the first planning period provides that the emission reductions anticipated from BART and other Clean Air Act programs may be all that is necessary to achieve reasonable progress in the first planning period. The commenters asserted that if ADEQ had assessed whether controls beyond BART or other Clean Air Act programs are necessary to make reasonable progress for the first planning period, ADEQ would have concluded that controls are not necessary and no further analysis is required.

The commenters stated that by performing a reasonable progress analysis ADEQ is taking a position that is inconsistent with the position ADEQ took in its Petition for Reconsideration of EPA's FIP and the State of Arkansas's Petition for Judicial Review of the SIP. Commenters pointed out that ADEQ urged EPA to reconsider whether controls are necessary at Independence given the 2015 monitoring data showing that Arkansas Class I areas are already meeting the reasonable progress goals in the FIP. The commenter pointed out that ADEQ argued that the FIP should be vacated because EPA ignored evidence that Arkansas would achieve reasonable progress without any additional controls.

The commenters asserted that if EPA approves ADEQ's proposed reasonable progress analysis, it might limit ADEQ's discretion in deciding against performing a reasonable progress analysis under similar conditions in the future. The commenters also stated that conducting an

unnecessary reasonable progress analysis now could limit ADEQ's ability to take advantage of technological developments, improvements in economic performance, and other improvements in subsequent planning periods. The commenters stated that ADEQ might be forced to assess reasonable progress controls even if visibility improvement exceeds the goals, increasing the likelihood that unnecessary controls would be imposed upon Arkansas point sources.

Response 22:

ADEQ disagrees with commenters who allege that ADEQ's proposed reasonable progress analysis is unnecessary and in conflict with positions taken by ADEQ and the State of Arkansas in comments on the FIP, ADEQ's Petition for Reconsideration, and the State of Arkansas's Petition for Judicial Review and arguments. A reasonable progress analysis is required under Clean Air Act 169A(g)(1) and EPA regulations and guidance for the first planning period. In the Arkansas Petition for Reconsideration of the FIP, Arkansas argued that EPA should reconsider whether reasonable progress controls are necessary on Independence based on then newly-released IMPROVE monitoring data showing that Arkansas was already under its 2018 reasonable progress goals.⁶² This request to consider more recent monitoring data in the Petition for Reconsideration is consistent with positions taken in the Proposed SIP. The Petition for Judicial Review filed in *Arkansas v. EPA* did not make substantive arguments that contradict the Proposed SIP. While the State's broader arguments in *Arkansas v. EPA* reflect a disagreement with EPA regarding the manner in which EPA performed its reasonable progress analysis and its ultimate conclusion, the State did not argue that EPA erred simply by performing an analysis.

Furthermore, ADEQ's conclusion in the Proposed SIP that no additional controls are necessary for reasonable progress is consistent with ADEQ's arguments. ADEQ is revising its requirement for LSC at Independence, which was meant to lock in visibility improvements already achieved, in response to other comments.

ADEQ disagrees with commenters that disregarded ADEQ's evaluation of whether additional controls were necessary for reasonable progress beyond BART and Clean Air Act programs and presumed that we should have come to the conclusion that no further analysis was required because Arkansas Class I areas were below the glide path. The implication that ADEQ did not consider whether additional controls were necessary for reasonable progress beyond BART and Clean Air Act programs is false. In addition, the reasonable progress analysis for ADEQ's 2008 SIP was disapproved because ADEQ reasoned that no four factor analysis was required because BART and other Clean Air Act programs would result in greater visibility improvement than the glide path.

ADEQ disagrees with commenters that performing a reasonable progress analysis limits the State's future discretion for future planning periods. The 2017 RHR Amendments apply to the second planning period and beyond. As a result, precedential value of this SIP, which is

⁶² Pet. For Recon., Docket No. EPA-R06-OAR-2015-0189, at p.2.

developed under the prior version of the Regional Haze regulation, is limited. In addition, EPA has stated an intention to revisit aspects of the 2017 RHR Amendments.⁶³

ADEQ concludes that, based on evaluation of the statutory reasonable progress factors and other relevant factors, it is reasonable to defer potential controls beyond BART and other Clean Air Act programs to future planning periods. This decision will allow ADEQ to take advantage of technological developments, improvements in economic performance, and other improvements in subsequent planning periods. ADEQ notes that states are required under regulations for the first planning period and the 2017 RHR Amendments to assess whether controls are necessary for reasonable progress even if the rate of visibility improvement exceeds that of the glide path.

This comment does not necessitate changes to the Proposed SIP.

Comment 23:

Commenters suggested corrections to ADEQ's characterization of CENRAP particulate source apportionment data. The Commenters pointed out an error in ADEQ's description of total light extinction contribution to Arkansas Class I areas on page 29 of the Proposed SIP. The commenter pointed out that "six percent" should be corrected to "seven percent." On page 31 of the Proposed SIP, the commenters suggested that ADEQ clarify that the cumulative contribution of natural, on-road, and non-road sources is approximately five percent of total light extinction rather than categorizing their contributions as "very small." The commenter points out that "very small" is a subjective characterization. The commenters also stated that values presented as "0" in Figures 6, 7, 8, and 9 should be expanded to show at least one non-zero digit, or should be footnoted to clarify that they are not zero.

Response 23:

ADEQ will make the recommended changes.

Comment 24:

Some commenters voiced concerns that ADEQ's reasonable progress analysis was a source-specific analysis focused solely on Independence. The commenters stated that Arkansas is not legally required to conduct a reasonable progress analysis on a source-specific basis and should not do so in the SIP. The commenters asserted that reasonable progress provisions are intended to address contributions for a wide range of sources and should be addressed on a source-category basis. Commenters stated that ADEQ's focus on a source-specific reasonable progress analysis sets a precedent that could force more sources to install controls in the second planning period.

Response 24:

⁶³ <https://www.epa.gov/visibility/epas-decision-revisit-aspects-2017-regional-haze-rule-revisions>

ADEQ disagrees with the commenters that object to ADEQ's proposed reasonable progress analysis stating that it is a source-specific analysis focused solely on Independence. Nevertheless, ADEQ is availing itself of the flexibility described in the EPA's 2007 Reasonable Progress Guidance to revise the SIP to more clearly apply the factors both broadly to the State as a whole as well as to Independence.

ADEQ began its proposed reasonable progress analysis by broadly looking at the various contributors to visibility impairment in Arkansas. See Section V.A. of the Proposed SIP. Through an examination of particulate source attribution, ADEQ narrowed the range of sources to consider for further analysis to point sources with SO₂ emissions greater than 250 tons per year averaged over the most recent three year period for which data was available. Three of the eleven point sources with recent emissions greater than 250/tons per year were subject-to-BART and were therefore eliminated from consideration of further controls. ADEQ then performed an SO₂-specific Q/D analysis of the eight remaining sources and selected any source with a Q/D value greater than or equal to ten for further analysis. Three sources had a Q/D value greater than or equal to ten: Independence, FutureFuel Chemical Company, and John W. Turk. FutureFuel was a BART-eligible facility that was eliminated because it did not meet the 0.5 dv subject-to-BART threshold in the 2008 Arkansas Regional Haze SIP. Therefore, ADEQ determined that a four factor analysis for FutureFuel was unnecessary during this planning period. John W. Turk began operation in 2012 with the best available control technology. Therefore, ADEQ determined that a four factor analysis for John W. Turk was unnecessary during this planning period. The only remaining source with a Q/D greater than or equal to ten was Independence, which the record demonstrates impacts Arkansas Class I areas and has no SO₂ control technology in place.

These circumstances as well as the unique circumstances surrounding EPA's arbitrary selection and analysis of Independence resulting in the selection of Dry FGD resulted in ADEQ determining that it is necessary to perform a four factor analysis for Independence to ensure a thorough and accurate record of the decisions in the SIP. Although a reasonable progress analysis is required, ADEQ's ultimate determination, which is further explained in Response 26 is that no further controls were necessary for reasonable progress.

ADEQ agrees with commenters that a four factor analysis can be performed for a broad source category. However, ADEQ disagrees with those commenters that assert that a four factor analysis should only be performed for broad source categories or that ADEQ's analysis in the Proposed SIP is precedent setting. ADEQ formulated the approach to evaluating whether additional controls were necessary for reasonable progress after consideration of key pollutants impacting visibility at Arkansas Class I areas, the 2007 "Guidance for Setting Reasonable

Progress Goals under the Regional Haze Program,” and reasonable progress analyses performed for other states for the first planning period.⁶⁴

Although ADEQ disagrees with the commenters’ characterization of ADEQ’s proposed reasonable progress analysis, ADEQ is making revisions in the final SIP to the reasonable progress analysis to reframe the analysis, more clearly apply relevant factors state-wide, and discuss additional factors described in other comments received. See Response 25(d).

Comment 25:

Commenters voiced concerns with respect to ADEQ’s four-factor analysis of Independence. Specifically, commenters took issue with ADEQ’s evaluation of two of the statutory factors: the cost of compliance and remaining useful life. In addition, commenters recommended changes to ADEQ’s evaluation of factors beyond the four statutory factors.

25(a):

Commenters suggested that, if the final SIP includes a source-specific reasonable progress analysis for Independence, ADEQ should account for all relevant information in its reasonable progress analysis, including the anticipated cease-to-use coal date. In particular the commenters asserted that the remaining useful life of Independence in any four-factor analysis should be based on Entergy’s anticipated cessation of coal-fired operations at Independence units by the end of 2030.

Response 25(a):

ADEQ disagrees with the commenter that ADEQ should base its four-factor analysis for Independence on a remaining useful life ending in 2030. Entergy’s proposed cessation of coal-fired operations date is not State or federally enforceable. The circumstances for Independence are different than those for White Bluff. White Bluff is a subject-to-BART facility for which ADEQ is compelled by statute to require installation of BART. That BART determination is influenced by the enforceable curtailment of the remaining useful life of the facility. Independence is not a subject to BART facility. ADEQ has determined that no controls are necessary for reasonable progress even without truncation of remaining useful life for Independence.

This comment does not necessitate changes to the Proposed SIP.

25(b):

Commenters took issue with ADEQ's evaluation of the cost of compliance for retrofit technology at Independence.

Some commenters suggested that ADEQ should have relied on costs and modeling results from Entergy based on CAMx modeling and certain costs that were disallowed by EPA in calculating the cost of controls. The commenters stated that based on Entergy's anticipated cease-to-use coal date and EPA control cost estimates, that the cost-effectiveness for Dry FGD at Independence would be \$5,026/ton at unit 1 and \$4,640/ton at unit 2. The commenters noted that these cost-effectiveness values exceed those that EPA agreed could be rejected for reasonable progress purposes for other state plans. The commenters explained that EPA has indicated that control costs found to be reasonable in the BART context may nonetheless be considered too costly in the context of reasonable progress.

Some commenters noted Entergy's cost-effectiveness estimates for Dry FGD at Independence in their 2015 comments on EPA's FIP, which was referred to in the Proposed SIP, do not comport with EPA's Control Cost Manual. The commenters also stated that Entergy's calculations were based on an unrealistically high uncontrolled SO₂ rate for design and cost determination of Dry FGD systems. The commenters stated that ADEQ must not rely on Entergy's 2015 cost-effectiveness calculations for Dry FGD at Independence.

Some commenters stated that ADEQ's analysis of the cost-effectiveness of LSC as a control for Independence is flawed. In particular, the commenters asserted that the cost-effectiveness should be zero because Independence units are already meeting 0.6 lb SO₂/MMBTU on an annual basis. The commenters noted that ADEQ evaluated emission reductions resulting from LSC based on the maximum 30-boiler operating day average emission rate over 2009–2013; whereas EPA's evaluation of anticipated emission reductions for Dry FGD for White Bluff was based on annual average SO₂ emissions over a 2009–2013 baseline with the minimum and maximum years excluded. The commenter stated that if ADEQ had excluded 2012 and 2010, as was done in EPA's analysis, none of the maximum 30-boiler operating day emission rates during the 2009–2013 baseline were above 0.6 lb SO₂/MMBtu. The commenter also noted that ADEQ used a longer period (2009–2016) over which to evaluate tons of fuel burned at each unit. The commenter stated that it is not clear why ADEQ used a longer period of data on tons of fuel burned at each unit compared to the 2009–2013 period used for baseline emissions. The commenter also noted that emission reductions were calculated based on reducing emissions to 0.6 lb SO₂/MMBtu; however, the commenter pointed out that Independence units' maximum thirty-boiler-operating-day averages over 2009–2016 would show compliance with a 0.6 lb SO₂/MMBtu rate if rounded to the nearest tenth.

Some commenters objected to ADEQ's rejection of scrubbers as reasonable progress controls in part because of Entergy and EPA's cost-effectiveness and the high capital costs of new scrubbers. The commenter asserted that ADEQ appears to claim that EPA cost-effectiveness estimates for Dry FGD were not reasonable costs of control based on screening threshold for reasonable progress used by Kentucky in their Regional Haze SIP. The commenter noted that in EPA's approval of the \$2000/ton threshold used by Kentucky, that their approval was used "[f]or the limited purpose of evaluating the cost of compliance for the reasonable progress assessment in this first regional haze SIP for non-EGUs."⁶⁵ The commenters pointed out that the cost-effectiveness for Dry FGD at Independence units 1 and 2 are well within the range of cost-effectiveness of other reasonable progress decisions finalized by other states or EPA. The commenters asserted that even if operated at lower capacity factors in the future, Dry FGD at Independence is still cost-effective compared to previous reasonable progress determinations finalized by other states or EPA. The commenters also argued that ADEQ failed to consider the possibility that Entergy might choose to meet a new SO₂ limit based on Dry FGD by retiring Independence and that the capital cost of replacement generation might be lower than the cost of new scrubbers.

Response 25(b):

ADEQ acknowledges that Entergy's CAMx modeling shows little impact on visibility at Arkansas Class I areas by Independence; however, ADEQ disagrees with the assertion that ADEQ should have relied on costs from Entergy's 2015 comments on the FIP. Entergy's analyses of costs for Dry FGD included certain costs that EPA has disallowed for consideration in cost-effectiveness calculations. As such, ADEQ relied upon EPA's costs for Dry FGD for Independence. To rely upon costs from Entergy's 2015 comments is unnecessary and inconsistent with EPA guidance and precedent in Regional Haze program cost-effectiveness calculations.

ADEQ disagrees with the use of cost-effectiveness of Dry FGD at Independence based on Entergy's cease-to-use coal date. Entergy's cease-to-use coal date for Independence is not a federally or state enforceable requirement. See Response 25(a). ADEQ will consider Entergy's plans to cease coal-fired operations at Independence as an additional relevant factor and will acknowledge these plans in the long-term strategy.

ADEQ agrees that control costs found to be reasonable in the context of BART may be considered too costly in the context of reasonable progress.

ADEQ disagrees with the commenters' assertions that the cost-effectiveness of LSC should be zero for Independence. If the traditional approach of using annual emission reductions were used, as opposed to the maximum thirty-day emissions rate, the cost-effectiveness value would near infinity. This would not provide a meaningful framework for comparison since there would

⁶⁵ 76 FR 78194 at 78206 (Dec. 16, 2011).

be low cost emission reductions as a result of compliance with a 0.6 lb SO₂/MMBtu emission rate at Independence. Although ADEQ does not agree with the commenter regarding the approach for calculating cost-effectiveness for LSC in the Proposed SIP, ADEQ will revise the baselines for emission rates and fuel burned to reflect 2009–2013 consistent with the baseline used for calculating cost-effectiveness of Dry FGD.

ADEQ will also replace EPA estimates of Dry FGD cost-effectiveness for Independence with estimates derived from Table 3.1 of Exhibit I to Entergy Arkansas's comments. In Table 3.1, Entergy calculated cost-effectiveness values based on nine years of remaining useful life. ADEQ estimates that, based on thirty years of remaining useful life, the cost-effectiveness of Dry FGD at Independence would be \$2,970/ton for unit 1 and \$2,742/ton for unit 2.⁶⁶ ADEQ will also specify that all calculations for LSC are based upon a compliance assumption of 0.60 lb SO₂/MMBtu.

In the Proposed SIP, ADEQ does not claim that cost-effectiveness estimates for Dry FGD fall outside the range of reasonable progress decisions finalized by other states and EPA. ADEQ does however note that states may set a reasonable progress threshold at lower levels, such as in the case of Kentucky, than are typical for BART. ADEQ also acknowledges that Dry FGD might be in the range considered cost-effective in other states even with a lower dispatch rate. Change in dispatch is one of the relevant factors considered by ADEQ in determining whether controls are necessary for reasonable progress. ADEQ also acknowledges that Entergy might choose to meet a new SO₂ limit by retiring Independence and that the capital cost of replacement generation might be more economic than the cost of Dry FGD. ADEQ has determined that, after consideration of the statutory reasonable progress factors—as well other relevant factors—that it is reasonable to defer further consideration of controls for Independence to subsequent planning periods. This determination is consistent with EPA guidance.

25(c):

Commenters asserted that ADEQ's consideration of visibility improvement anticipated from installation of controls at Independence was flawed. Specifically, commenters stated that ADEQ's characterization of SO₂ emission rates at Independence is misleading and should be deleted. The commenters noted that CALPUFF modeling demonstrates that an emission rate of 0.6 lb SO₂/MMBtu on a thirty-day rolling average at Independence based on the use of LSC

⁶⁶ ADEQ revised the annualized capital cost for Dry FGD at Independence included in Exhibit I to Entergy's comments based on a thirty-year remaining useful life for the Dry FGD equipment because no enforceable commitment to cease operations by 2030 is in place for Independence. The revised annualized capital cost is based on a capital recovery factor calculated for a thirty-year amortization period in accordance with Chapter 2 of the EPA Control Cost Manual. ADEQ's calculations are included in Appendix F of the final SIP.

<https://www.epa.gov/sites/production/files/2017-12/documents/epacmcostestimationmethodchapter_7thedition_2017.pdf>

would yield a visibility improvement of 0.112 deciviews for Caney Creek and 0.302 deciviews for Upper Buffalo.

Response 25(c):

ADEQ proposed to require LSC for Independence to lock in visibility improvements already observed at Arkansas and Missouri Class I areas due to Entergy's choice to burn lower sulfur coals than required by permit at Entergy Independence Unit 1 and Unit 2. After evaluation of comments received, ADEQ understands that an emission rate of 0.6 lb SO₂/MMBtu based on LSC would not be locking in an existing emission rate for Independence and therefore does not represent locking in existing visibility improvements. ADEQ acknowledges the modeled visibility impacts at Arkansas Class I areas of LSC provided by commenters. ADEQ will revise the reasonable progress analysis to reflect that LSC at Independence would be an additional control that is not necessary to achieve reasonable progress and remove the comparison of thirty-day SO₂ emission rates to Independence's three-hour SO₂ emission limit.

25(d):

Some commenters suggested that ADEQ consider other relevant factors to justify reasonable progress. Commenters noted that it is clear that the four reasonable progress statutory factors set forth in Clean Air Act 169A(g)(1) must be considered by states in a reasonable progress analysis; however, the commenters also noted that EPA guidance is clear that states have the authority to consider other relevant factors. The commenters stated that there is no requirement for a reasonable progress analysis to mirror a BART analysis. The commenters asserted that ADEQ's approach to evaluating controls for reasonable progress endorses the 2017 RHR Amendments, which limits state discretion in conducting a reasonable progress analysis, and that ADEQ is unnecessarily setting a precedent that may be difficult to avoid in future planning periods.

Specific other relevant factors (beyond the statutory four factors) that commenters suggested ADEQ consider included the implication of compliance costs to the health and vitality of industries within the state, the fact that Arkansas Class I areas are already below the glide path for the first planning period, the relative contribution of light extinction to Arkansas Class I areas from point sources located within the Arkansas, the overall contribution to visibility impairment by source categories within and outside of Arkansas, and impacts on electricity rates in Arkansas communities. Commenters stated that given the small effect of light extinction in Arkansas Class I areas from Arkansas point sources, installing emission controls on Independence would not result in meaningful change at either Class I area. Commenters supported this assertion by noting that EPA has approved a similar conclusion by another state and recently approved ADEQ's decision to screen out Arkansas point sources from further evaluation of NO_x for reasonable progress controls in light of (1) the low level of visibility impairment due to NO_x emissions from those sources and (2) the fact that additional NO_x controls are not anticipated to yield meaningful visibility improvements. Commenters also noted that installation of Dry FGD at

Independence would result in \$1 billion dollars in costs which could increase electricity rates, with significant impacts on Arkansas communities, many of which are already facing economic hardship.

Some commenters recommended that ADEQ and sources within the state should be given an opportunity to consider more broadly the complete set of relevant factors and await resolution of the challenge to EPA's 2017 RHR Amendments.

Other commenters stated that it is arbitrary and capricious for ADEQ to purport to consider visibility improvement, but then not weigh the visibility benefits gained against the cost of controls when making its control determination. The commenter asserts that ADEQ does not mention the visibility benefits of new scrubbers when it weighs all of the information considered.

Response 25(d):

ADEQ agrees with commenters that other relevant factors beyond the statutory four reasonable progress factors can be considered by states in determining whether additional controls are necessary for reasonable progress. ADEQ agrees with the commenters that there is no requirement for a reasonable progress analysis to mirror a BART analysis; however, ADEQ disagrees with commenters' assertions that ADEQ's approach to evaluating controls for reasonable progress in the SIP endorses the 2017 RHR Amendments. ADEQ also disagrees with the commenters that ADEQ's approach is precedent setting. See Response 19.

ADEQ recognizes the commenters' suggestions for additional factors to consider. The Proposed SIP discusses some of the suggested factors in the reasonable progress analysis, such as the relative contribution to light extinction by source categories (including point sources) within and outside of Arkansas as well as the fact that Arkansas Class I areas are below the glide path. The information provided by commenters concerning additional relevant factors further supports ADEQ's conclusion that no additional controls are necessary to ensure reasonable progress during the first planning period. Although many of the factors brought up by commenters are referenced in the SIP, ADEQ will reframe the reasonable progress discussion in the SIP to clarify our consideration of the four factors and other relevant factors.

ADEQ disagrees with those commenters that suggested that ADEQ wait to finalize the SIP until the resolution of challenges and administrative changes to the 2017 RHR Amendments. The Proposed SIP complies with Regional Haze requirements for the first planning period. The 2017 RHR Amendments apply to the second planning period and beyond. See Response 19.

ADEQ acknowledges that, in its proposed determination of reasonable progress controls for Independence, ADEQ did not include language regarding the visibility benefits of new scrubbers. Due to other comments, ADEQ has determined that no additional controls are necessary to ensure reasonable progress; however, ADEQ will provide further explanation of the

Department's rationale, including discussion of visibility benefits that would be anticipated for new scrubbers.

Comment 26:

Some commenters agreed with ADEQ's determination that no add-on controls beyond BART are necessary for reasonable progress for the 2008–2018 planning period, while others thought that Independence should be required to install Dry FGD. In addition, commenters opposed requiring LSC at Independence as a control for reasonable progress.

Some commenters opposed any controls beyond BART, both add-on and LSC, for reasonable progress during the first planning period. Commenters stated that, given the pace of visibility improvement in Arkansas Class I areas in comparison to the uniform rate of progress and the reasonable progress goals in EPA's FIP, the imposition of reasonable progress controls are unnecessary for the first planning period and should not be required in the Proposed SIP. Some commenters pointed out inherent limitations and uncertainty in CALPUFF modeling with respect to visibility improvements anticipated from controls at Independence. The commenters also pointed out that Arkansas point sources contributed less than 3.5% of sulfate light extinction at Arkansas Class I areas and that White Bluff contributes only a fraction of statewide point source SO₂ emissions. Commenters stated that historic and continued use of LSC at White Bluff (and other Arkansas coal-fired power plants) has been sufficient to meet reasonable progress visibility requirements. Some commenters stated that no controls that would be installed after 2018 should be included in the SIP for reasonable progress because the controls could not be implemented before the end of the first planning period.

In comments on the Proposed SIP, Entergy disagreed with ADEQ's proposed determination that LSC should be required for Independence as a reasonable progress control, but stated that they would agree to take an emission limit based on LSC at Independence as a SIP strengthening measure. Entergy argues that LSC is not existing control and could not be implemented until the second planning period due to existing contracts which dictate Entergy's coal supply through 2019.

Some commenters alleged that ADEQ's determination that no additional controls are required at Independence in part because the state is on the glide path toward natural visibility is unlawful. The commenters noted EPA's explanation of its 2012 disapproval of Arkansas's 2008 Regional Haze SIP in which EPA states that "being on the 'glide path' does not mean that a state is allowed to forgo an evaluation of the four statutory factors." The commenters asserted that being on the glide path does not relieve the state from conducting a reasoned analysis and that if it is reasonable to make more progress than the uniform rate of progress a state must do so.

Response 26:

In response to comments received, ADEQ will revise its reasonable progress controls determination. The information provided by commenters regarding the \$1 billion cost of Dry FGD that would be passed on to ratepayers, the fraction of the relative contribution from Arkansas point sources to light extinction at Missouri and Arkansas Class I areas, and market-driven changes in the electricity generation mix—including Entergy’s planned cessation of operations at Independence by the end of 2030—further support ADEQ’s determination that it is not reasonable or necessary to require further controls beyond BART and existing Clean Air Act requirements for reasonable progress during the first planning period. See Response 25(d). As discussed in Response 25(c), ADEQ’s proposed emission limit of 0.6 lb SO₂/MMBtu does not represent locking in an existing voluntary emission reduction choice by Entergy at Independence, which was the basis for requiring such an emission limit for the purposes of reasonable progress in the Proposed SIP. ADEQ further agrees with the commenters that neither Dry FGD nor LSC could be implemented at Independence before the end of the 2018 planning period. Therefore, ADEQ finds that it is reasonable to defer requirements for emission reductions from Independence to future planning periods.⁶⁷

ADEQ disagrees with those commenters that asserted that ADEQ’s determination that no additional controls are required at Independence in part because the state is on the glide path toward natural visibility is unlawful. ADEQ considered the four statutory reasonable progress factors, as well as other relevant factors, in a reasoned analysis of whether additional controls are reasonable and necessary to ensure reasonable progress during the first planning period. Based on this consideration, and the additional information provided in comments, ADEQ has determined that no additional controls are reasonable or necessary at Independence for reasonable progress during the first planning period. In addition, ADEQ notes that the reasonable progress goals included in the Proposed SIP do show more progress than the uniform rate of progress.

ADEQ will revise its long-term strategy to reflect Entergy’s proposal to require LSC at Independence as a SIP-strengthening measure; however, after evaluation of the comments, ADEQ does not find that LSC at Independence is required for reasonable progress during the first planning period.

Comment 27:

Some commenters asserted that ADEQ may only require additional controls for reasonable progress if further action beyond BART and other Clean Air Act programs is necessary for reasonable progress in this planning period. The commenters noted that the Clean Air Act

⁶⁷ In EPA’s 2007 “Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program,” EPA states: “In deciding what amount of emissions reduction is appropriate in setting the RPG, you should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for you to defer reductions to later planning periods in order to maintain a consistent glidepath toward the long-term goal.”

requires plans to “contain such emission limits, schedules of compliance, and other measures as may be necessary to make reasonable progress.”⁶⁸ The commenter also pointed out that EPA’s 2007 reasonable progress guidance makes clear that reasonable progress controls may not be necessary in the first planning period, noting that “[g]iven the significant emission reductions that we anticipate to result from BART” and other Clean Air Act programs “it may be all that is necessary to achieve reasonable progress in the first planning period.” The commenters further pointed out the guidance states that it is reasonable to defer reductions to later planning periods in order to maintain a consistent glide path toward the long-term goal.

Other commenters asserted that being on the glide path does not relieve the state from conducting a reasoned analysis and that if it is reasonable to make more progress than the uniform rate of progress, a state must do so.

Response 27:

ADEQ acknowledges the comment regarding reasonable progress in the first planning period and agrees with the Commenters’ interpretation of reasonable progress. ADEQ acknowledges the commenters’ accurate statement that EPA’s 2007 reasonable progress guidance makes clear that reasonable progress controls may not be necessary in the first planning period, noting that “[g]iven the significant emission reductions that we anticipate to result from BART” and other Clean Air Act programs “may be all that is necessary to achieve reasonable progress in the first planning period.”

Given this statutory authority and associated guidance, ADEQ finds that the emissions reductions anticipated from BART and other Clean Air Act Programs are all that is necessary to achieve reasonable progress in the first planning period. ADEQ has revised the SIP to reflect both this determination and the interpretation of reasonable progress. As set forth in the revised reasonable progress analysis, ADEQ has determined that it is not necessary for any controls to be installed in order to make reasonable progress in the first planning period based on an analysis using the four reasonable progress factors.

ADEQ agrees with the commenters that being on the glide path does not relieve the state from conducting a reasoned analysis and making additional progress if it is reasonable to do so. ADEQ has performed a reasoned analysis and determined in the Final SIP that it is not necessary or appropriate to require additional controls to make additional progress during the first planning period.

No revisions to the SIP are necessary due to this comment.

Comment 28:

⁶⁸ 42 USC 7491(b)(2)

Some commenters supported ADEQ's proposed revisions to the long-term strategy and other suggested revisions to account for anticipated changes in nitrogen oxide emissions and operations of Entergy power plants. Some commenters noted that the long-term strategy recognizes planned retirements of large power plants in Texas during 2018 that affect Arkansas Class I areas. Commenters pointed out that there is another retirement anticipated for 2018 in Tennessee. The commenters stated that the combined emission reductions resulting from the retirements of these plants in Texas and Tennessee would result in greater emission reductions than anticipated from EPA's FIP or the Proposed SIP. The commenters also pointed out that the combined emission reductions anticipated from the Texas and Tennessee power plant retirements is greater than the maximum emissions from White Bluff and Independence combined. The commenters asserted that these emission reductions are predicted to ensure that visibility will remain well below the glide path until the end of the second planning period. Some commenters stated that ADEQ should include in its long-term strategy Entergy's planned cease-to use coal dates for White Bluff and Independence, Entergy's planned retirement date for Lake Catherine, and the low NOx burners Entergy is installing at White Bluff and Independence. Other commenters state that any future retirements of stationary sources that may occur after the end of the first planning period should be addressed in long-term strategies of future planning periods.

Response 28:

ADEQ acknowledges and appreciates the commenters support for recognition of planned retirements of large power plants in Texas during 2018. ADEQ also appreciates the additional information the commenters provided regarding a planned retirement in Tennessee during 2018. ADEQ will acknowledge in the long-term strategy, but will not render enforceable Entergy's planned changes in operations at Independence and Lake Catherine and the additional NOx control technology that Entergy is installing at White Bluff and Independence. The future changes in operation at Independence and Lake Catherine take place in the second planning period and third planning period and will factor into Arkansas's consideration of reasonable progress and long-term strategy for future planning periods. ADEQ has in place an EPA-approved SIP that addresses NOx from EGUs by reliance on CSAPR; therefore, enforceable facility-specific NOx emissions are not required for EGUs under Arkansas's Regional Haze program.

ADEQ disagrees with those commenters that instructed that retirements occurring after 2018 should be deferred to the second planning period SIP. ADEQ has factored into its BART analysis the cessation of coal-fired operations for White Bluff and thus proposed the inclusion of an administrative order that would render such cessation enforceable in the long-term strategy. See Response 20(c).

Comment 29:

Some commenters objected to ADEQ's proposed request for EPA to replace previously SIP-approved emission limits in Regulation No. 19 with the same limits contained in administrative orders. Commenters asserted that ADEQ is attempting to rescind and re-propose the already approved limits. The commenters stated that this was confusing, unnecessary, and re-opens long settled BART determinations for additional review and comment. The commenters state that BART is a one-time requirement and that neither the Clean Air Act nor EPA's Regional Haze Regulations provide a basis to review and re-evaluate approved BART determinations. The commenter recommends that if ADEQ is interested in moving these BART limitations into a different section of chapter of its SIP-approved regulations, that ADEQ can do so through administrative changes to Arkansas's regulations rather than asking EPA to eliminate them from the SIP and reapprove them. Commenters also stated that ADEQ's proposed request potentially exposes ADEQ and subject facilities to legal challenges when no change is occurring. The commenters noted that these emission limits are in the current Title V permits for the respective facilities.

Response 29:

ADEQ acknowledges the comment and disagrees that ADEQ is attempting to rescind and re-propose already-approved limits. ADEQ is merely incorporating previously-approved limits in a new enforceable mechanism. ADEQ is not seeking to alter EPA's approval of those limits. For example, ADEQ specifically states on the second page of the introduction to the Proposed SIP that "Arkansas is not revising portions of the 2008 AR RH SIP that were approved."⁶⁹ Similarly, ADEQ specifically states when no changes are needed with regard to a determination that has been previously approved by EPA when addressing that particular pollutant in the SIP introduction.⁷⁰ While ADEQ acknowledges that the inclusion of these limits in this action may be subject to public notice and comment, the BART determinations were included in the 2008 Arkansas Regional Haze SIP and approved in EPA's March 12, 2012 final rule.⁷¹

Although ADEQ disagrees with the commenters regarding their assertions regarding the "reopening" of previously approved provisions, ADEQ will revise the administrative orders to remove previously approved BART determinations, which match those included in APC&EC regulations, in order to alleviate further confusion.

Comment 30:

Some commenters asserted that the Proposed SIP violates Clean Air Act anti-backsliding requirements. Specifically, the commenters stated that the proposed SIP would authorize significantly more SO₂ emissions and produce worse air quality than the existing FIP without including emission reductions beyond those required in the FIP to compensate for allowing for

⁶⁹ Proposed SIP at page 2.

⁷⁰ See e.g. Proposed SIP at p. 25.

⁷¹ 77 FR 14,604

higher SO₂ emission rates from Independence and White Bluff. The commenters asserted that Clean Air Act Section 110(l) prohibits plan revisions that would interfere with an existing requirement to make reasonable further progress, including a BART determination, as the Clean Air Act's applicable requirements included the Regional Haze Program's BART requirements. The commenters supported their assertions with citations to court decisions upholding EPA's interpretation of Section 110(l) as prohibiting plan revisions that would increase emissions or worsen air quality.

Response 30:

ADEQ disagrees that the Proposed SIP violates the Clean Air Act's anti-backsliding requirements and that the Proposed SIP would interfere with any existing requirement to make reasonable further progress or any other applicable requirement under Section 110(l). The Sixth Circuit Court of Appeals has held that, under section 110(l), an agency may approve a SIP revision unless it will make air quality worse.⁷² This holding does not apply to this Arkansas Regional Haze SIP revision. If approved, the Proposed SIP would not affect any emission controls impacting visibility that are already in place. The SO₂ emission limitations for White Bluff and Independence included in the FIP have been judicially stayed and had not yet become effective at the time of the stay.⁷³ Because the FIP's requirements have not yet, and may never, become effective, the standard that allows an agency to approve a SIP revision unless the agency finds it will make air quality worse does not apply.

In addition, the commenters have not provided any information in support of their claim that the FIP would interfere with any reasonable further progress requirements under 40 CFR 51.1012. "Reasonable Further Progress" is a requirement that only applies to nonattainment areas.⁷⁴ Arkansas is in full attainment with all NAAQS, including the SO₂ NAAQS, and therefore does not have any nonattainment areas or reasonable further progress requirements.

Finally, ADEQ finds commenters projected emissions contain an inherent degree of uncertainty. Actual SO₂ emissions from EGUs vary based upon how much they dispatch onto the grid. These dispatch trends are often unpredictable to the impact of factors include overall economic growth, energy prices, and economic conditions. This comment does not necessitate changes to the Proposed SIP.

Comment 31:

Some commenters expressed concerns that electricity and manufacturing costs could increase due to the approaches in the Proposed SIP. Commenters pointed out that the cost of installing pollution controls or taking other actions required under the Proposed SIP will be the initial responsibility of the public utility plant owners and operators; however, the owners and operators

⁷² *Kentucky Res. Council, Inc. v. E.P.A.*, 467 F.3d 986, 995 (6th Cir. 2006)

⁷³ Order granting Am. and Sub. Mot. for Stay, Case No.16-4270, March 7, 2018.

⁷⁴ 40 C.F.R. § 51.1003

are permitted under Arkansas law to directly pass through and recover the costs and expenses of installing, operating and maintaining pollution controls from electric utility customers and ratepayers through electricity rates and tariffs filed with the Arkansas Public Service Commission. The commenters noted that the utility plant owners and operators are permitted to seek approval from the Arkansas Public Service Commission to recover from electric utility customers and ratepayers the cost of replacement power or capacity needed to replace the premature retirement of power plants or the cost of switching fuels. The commenters noted that providers of goods and services to power plants would be harmed financially, if instead of installing additional controls, any of the power plants were to curtail or modify operations or close pursuant to the Proposed SIP.

Response 31:

ADEQ appreciates the remarks of the commenters and acknowledges their concerns regarding costs that could be passed on to the utility customers. Requiring installation of scrubbers at White Bluff and Independence, as some have suggested and required by EPA’s FIP, would likely result in much greater electricity rate impacts due to the cost of purchase and installation of equipment, an increase in parasitic load, and disposal of waste products. The inclusion of an enforceable cessation of coal-fired operations date for White Bluff in the Proposed SIP was necessary to comply with BART guideline requirements for taking into account the planned operational changes for White Bluff by Entergy as part of ADEQ’s BART analysis. See Response 20(b). In comparison to the FIP, the Proposed SIP would eliminate over two billion dollars in costs for installation of scrubbers at White Bluff and Independence or the replacement generation costs in 2021 should Entergy choose to close White Bluff and Independence instead of complying with FIP emission limits.⁷⁵

Whereas it may be true that utility plant owners may seek permission from the Arkansas Public Service Commission to recover costs of replacement generation, it is equally true that the Arkansas Public Service Commission can deny such requests if not deemed prudent. Another function of the Arkansas Public Service Commission is “ensuring that customers are not charged excessive rates for service.”⁷⁶ The approach that ADEQ has chosen ensures compliance with Regional Haze Rule requirements at a lower cost than EPA’s FIP while continuing to protect the visibility at Class I areas into the future.

This comment does not necessitate changes to the Proposed SIP.

Comment 32:

⁷⁵ Entergy (2017). “Updated Five-Factor Analysis for SO₂ for Units 1 and 2” included in Appendix D. Entergy (2018) “Supplemental Information Analysis of Reasonable Progress Arkansas Regional Haze Program First Planning Period” included as Exhibit I to Entergy Arkansas Inc., comments on the Proposed SIP

⁷⁶ Arkansas Public Service Commission. Welcome to the Arkansas Public Service Commission’s Website. <http://www.arkansas.gov/psc/>.

Some commenters argued that reliance on an unsigned administrative order in the Proposed SIP is improper because it is not enforceable and others recommended revisions to specific findings of fact or orders included in the proposed Entergy administrative order.

Some commenters suggested modification or deletion of certain provisions in the proposed Administrative Order for Entergy. Specifically, the commenters stated that both the SIP and administrative order should explicitly recognize that early closure or cessation of coal at White Bluff is not required in connection with the use of LSC as BART. The commenters also recommended that the administrative order in Paragraph 10 of the Findings of Fact should explicitly recognize that no additional controls or emission limitations are necessary at Independence in order to achieve reasonable progress during the first planning period. The commenters stated that clarification is needed to emphasize that the reference to future White Bluff operations is informational and is not intended to create mandatory, federally enforceable requirements of the SIP that the commenter argues would be contrary to law. The commenters stated that Paragraph 3 of the Order should be modified to recognize that any early retirement or cessation of the use of coal at White Bluff is contingent on other regulatory approvals for Entergy and the co-owners of White Bluff, and thus cannot be the basis of an enforceable limitation under the administrative order. The commenters suggest that Paragraph 5 of the Order should be removed or modified. The commenters applauded ADEQ's use of Paragraph 10 of the Order to allow modification of the Administrative Order during future Regional Haze Program planning periods to account for ever-changing circumstances that could materially impact future reasonable progress assessments or long-term strategies. The commenters stated that the administrative order should also include a provision for public notice and comment on any future modifications to the administrative order so as to ensure that stakeholders are able to fully scrutinize such modifications and provide the Department with valuable input.

In comments on the Proposed SIP, Entergy asserted that ADEQ should include in the administrative order other requirements for planned changes in operation at Entergy units. Specifically, Entergy stated that the administrative order should include and render enforceable their proposed cessation of coal-fired operations dates for White Bluff and Independence and their anticipated retirement date for Lake Catherine. Entergy also states that the administrative orders should include and make enforceable reduced NO_x emission rates for White Bluff and Independence based on their installation of low NO_x burners. Entergy states that inclusion of these developments in the administrative order applicable to Entergy will make them enforceable, as required by regulations, and ensure that ADEQ has a defensible long-term strategy that maintains Arkansas's Class I areas on the glide path.

Entergy also recommended revisions to specific provisions of the proposed administrative order for Entergy. Specifically, Entergy stated that Order 7 should be removed because Lake Catherine Unit 4 no longer has the capability to burn fuel oil. Entergy stated that this was reflected in its Title V permit for Lake Catherine. Entergy also stated that the discussion of the impacts of the White Bluff and Lake Catherine units on Arkansas Class I areas should be revised or omitted.

Entergy also pointed out that Order 8 would require installation of a CEMS on White Bluff Auxiliary Boiler, which is unnecessary because it operates infrequently and was not required by EPA. Entergy also stated that the administrative order language could be interpreted to require Lake Catherine Unit 4 to install a CEMS, which was not required by EPA. EPA determined that a different methodology based on currently installed monitoring equipment at Lake Catherine Unit 4 was acceptable.

Commenters also suggested that ADEQ should remove the previously approved particulate matter and SO₂ limits from the administrative order.

Some commenters stated that ADEQ improperly relied on an administrative order for enforceability of the SIP that is vague and unenforceable. The commenters argued that the order violates both the requirements that BART include enforceable emission limits as well as the requirement that BART be installed and operated as expeditiously as possible. The commenters asserted that ADEQ cannot rely on a draft administrative order in the Proposed SIP. The commenters argued that even if the administrative order were not in draft form, the terms of the administrative order would still be vague and unenforceable. The commenters stated that the draft order does not create an affirmative obligation to shut down White Bluff. The commenter states that the limit in the order, which is contingent upon Entergy's execution of intended changes as indicated in their comments to EPA on the FIP, is not an enforceable limit under BART guidelines. The commenters stated that, in their comments on the FIP, Entergy merely proposes to cease burning coal and is prepared to take a commitment. The commenters also observed a discrepancy between the administrative order's requirement for compliance with execution of intended changes in operation by the end of 2030; whereas, Entergy's updated BART analysis is based on an assumption that White Bluff will cease firing coal by December 31, 2028. The commenters further pointed out that there is a reopener included in the administrative order for consistency with unspecified future state plans. The commenters also pointed out that whether Entergy ceases to burn coal appears contingent on receiving approval from the Arkansas Public Service Commission and approval of the SIP by EPA. The commenters asserted that the contingent nature of ADEQ's BART determination is unlawful. The commenters also stated that the proposed order's failure to require White Bluff to take a specific action by a specific date violates the statutory requirements for the timing of installation and operation of BART. The commenters noted that EPA's BART guidelines make clear that where the remaining useful life of a source affects the BART determination, the date the facility permanently stops operations "must be assured by a federally- or state-enforceable restriction preventing further operation."

Some commenters noted that the Proposed SIP and Administrative order allow Entergy three years to burn through existing stocks of higher sulfur coal. The commenters stated that if ADEQ selects LSC for Entergy, this technology is available regardless of existing stocks of dirtier, higher sulfur coal.

Response 32:

ADEQ agrees with the commenter that an unsigned order is not enforceable. ADEQ intends to execute the administrative orders (AOs) prior to finalization of the SIP. ADEQ presented the unsigned administrative orders for public notice prior to execution for the purpose of soliciting input from the public on the substance of the orders. The orders will become enforceable prior to an EPA decision on approval or disapproval into the Arkansas SIP.

ADEQ agrees with the commenters that the early closure or cessation of coal at White Bluff is not an explicit BART determination. The BART determination for White Bluff of LSC is based on analysis of the five factors that took into consideration the remaining useful life. ADEQ has incorporated Entergy's enforceable closure commitment into the AO to reflect the plans that Entergy has made publicly available. See Response 20(b).

ADEQ disagrees with the commenters that clarification is needed to emphasize that the reference to future White Bluff operations is informational and is not intended to create mandatory, federally enforceable requirements of the SIP that the commenter argues would be contrary to law. As previously stated, the reference to future White Bluff operations is not informational, but is an enforceable requirement incorporated into the administrative order to accurately reflect Entergy's planned cessation of coal-fired operations at the facility and guarantee timely action on that commitment. This certainty is necessary to allow consideration of Entergy's planned changes under the remaining useful life factor of the BART five-factor analysis. If approved into the SIP, all requirements of the administrative orders will become federally enforceable including the requirements that Entergy carry out its planned cessation of coal.

ADEQ disagrees with the commenter's recommendations that the Findings of Fact—referred to as “Statement of Basis” in the final AO—in the White Bluff administrative order should explicitly recognize that no additional controls or emission limitations are necessary at Independence in order to achieve reasonable progress during the first planning period. ADEQ has revised its reasonable progress analysis and determined that no additional controls are necessary for the first planning period. This determination is sufficiently clear and does not need to be reflected in the Entergy administrative order.

ADEQ also disagrees that Paragraph 3 of the Order should be modified to recognize that any early retirement or cessation of the use of coal at White Bluff is contingent on other regulatory approvals for Entergy and cannot be the basis of an enforceable limitation under the administrative order. Entergy is responsible for obtaining any other regulatory approvals in order to meet its commitment to cease the use of coal at White Bluff. The existence of any other applicable regulatory requirements does not preclude the use of this administrative order as an enforceable mechanism to ensure that Entergy carries out its planned cessation of coal. In addition, the BART guidelines clearly allow the compliance date for BART to be contingent upon EPA approval. ADEQ will modify the administrative order to include a severability

provision in the event of a requirement or provision in the administrative orders is held illegal or unenforceable in a judicial proceeding or is disapproved by EPA.

ADEQ disagrees with the commenters that suggested that Paragraph 5 of the Order should be removed or modified. As previously discussed in Response 25(c), 25 (d), and 26, ADEQ has determined that no further controls are needed to achieve reasonable progress in the first planning period. Nevertheless, Entergy has voluntarily proposed that ADEQ include LSC as a control for Independence in the long-term strategy. Therefore, no changes to Paragraph 5 of the Proposed Entergy order are necessary in response to this comment.

ADEQ agrees with the commenters that applauded ADEQ's use of Paragraph 10 of the Order to allow modification of the Administrative Order during future Regional Haze Program planning periods to account for ever-changing circumstances that could materially impact future reasonable progress assessments or long-term strategies. However, ADEQ notes that it has moved this statement to the Findings of Fact because it is factual statement of the potential impact of reasonable progress analyses in future planning periods. ADEQ has modified the statement to clarify that this is merely a statement of the regulatory requirement to perform a reasonable progress analysis for each planning period. As such, the substance of Paragraph 10 of the Order section of the administrative order is more appropriate in the Findings of Fact due to its factual nature. This relocation will not preclude ADEQ from taking the actions stated in that paragraph. In addition, ADEQ has added a provision addressing the effect of specific circumstances that might lead to the modification of the order or otherwise affect the future enforceability of provisions in the AOs including if federal legislation or a federal court modifies that regional haze program or the Arkansas SIP, respectively.

ADEQ disagrees that the administrative order should include a specific provision for public notice and comment on any future modifications to the administrative order so as to ensure that stakeholders are able to fully scrutinize such modifications and provide the Department with valuable input. However, it is appropriate to clarify how it will address potential future modifications, circumstances that might lead to future modifications, and provide assurances in the SIP that such changes will be made only after notice and comment. In order to do this, ADEQ has added language on page 2 that clarifies the steps ADEQ will take if the parts of the AOs are modified and provides assurances that ADEQ will provide a notice and comment period for any changes to the SIP or AOs. ADEQ has also added an additional provision in the AOs to clarify circumstances that may lead to future modifications including the effect of legislation or federal court decisions on the AOs.

In addition, the AOs included with the final SIP will be public noticed consistent with ADEQ's practice regarding other types of administrative orders, and the public notice requirements in the

Clean Air Act regarding SIP revisions.⁷⁷ No additional language is necessary to the AO as a result of this comment.

ADEQ disagrees that other requirements for planned changes in operation at Entergy units should be included in the administrative order. Based on an analysis using the reasonable progress factors, ADEQ has concluded that no other requirements are necessary to achieve reasonable progress including any planned changes at Entergy Independence or Lake Catherine. As a result, it is not necessary for ADEQ to include any such changes in the administrative order. However, ADEQ has revised the Proposed SIP to take into account the impacts of these planned changes regarding Lake Catherine and Independence in the long-term strategy.

ADEQ acknowledges the commenter's request for enforceable reduced emissions rates based on their installation of low NOx burners. However, ADEQ has already proposed and received approval of a Regional Haze SIP revision intended to address NOx requirements.⁷⁸ No additional NOx requirements are necessary for inclusion in this SIP revision or administrative orders. As a result, ADEQ disagrees with the commenter.

ADEQ disagrees that Order Paragraph 7 should be removed because Lake Catherine Unit 4 no longer has the capability to burn fuel oil. Its inclusion in the order provides assurance that, should changes occur such that Lake Catherine Unit 4 is capable of burning fuel oil, a new BART determination for fuel oil would be required before such fuel is burned. ADEQ notes that compliance with Order Paragraph 7 will not be an added burden on the facility due to its inability to burn fuel oil.

ADEQ agrees that Paragraph 8 of the Findings of Fact—referred to as Statement of Basis in the final AO—should be revised to simply specify that the four units were determined to be subject-to-BART in the 2008 SIP. ADEQ notes the commenter disputes that accuracy of the impacts of Lake Catherine.

ADEQ agrees that the requirement in Paragraph 8 of the Order section of the administrative order is not necessary as applied to White Bluff Auxiliary Boiler due to the infrequent operation of that unit. ADEQ will revise the order to reflect this.

ADEQ will remove these limits from the administrative orders. See Response 29.

ADEQ agrees that certain elements of the Entergy Administrative Order were insufficiently clear and has revised the proposed Entergy Administrative Order to clarify Entergy's planned closure of White Bluff is an enforceable requirement. This change is necessary to properly apprise the public of Entergy's planned changes and ensure enforceability of the administrative order. These

⁷⁷40 C.F.R. § 51.102; APC&EC Regulation No. 8.

⁷⁸

changes are consistent with Entergy's Updated BART Five-Factor Analysis for White Bluff Units 1 and 2, which is now publicly-available. Previously, Entergy's specific commitment to closure by December 31, 2028 had among information that had been asserted to have been a trade secret within the meaning Arkansas Pollution Control and Ecology Commission (APC&EC) regulations and the Arkansas Trade Secrets Act.⁷⁹ Now that this information can become subject to public scrutiny, ADEQ has incorporated the specific date into administrative order and the SIP generally.

ADEQ disagrees that whether Entergy ceases to burn coal is contingent on approval of the SIP by EPA. The requirement for Entergy to cease the use of coal is not conditional, and it is Entergy's responsibility to obtain any regulatory approvals needed to meet the commitment in the Entergy Administrative Order. Nevertheless, ADEQ's clarification to the administrative order should ensure that there is no further confusion regarding the requirement that Entergy complete its intended cessation of coal no later than December 31, 2028.

As previously stated, the provision acknowledging ADEQ's ability to revise this administrative order in future planning periods for consistency with future requirements and plans has been modified to clarify that it is intended to reflect existing regulatory requirements and relocated to the findings of fact section to ensure that it will not be interpreted as anything other than a statement of fact. In addition, any other applicable requirements necessary to allow Entergy to lawfully cease the use of coal at White Bluff are the responsibility of Entergy to meet. ADEQ agrees that the BART guidelines make clear that where the remaining useful life of a source affects the BART determination, and that the date the facility permanently stops operations "must be assured by a federally- or state-enforceable restriction preventing further operation." ADEQ has clarified the language in the Entergy administrative order to ensure there is an understanding that Entergy's commitment meets this requirement.

Some commenters noted that the Proposed SIP and Administrative order allow Entergy three years to burn through existing stocks of higher sulfur coal. After consideration of the comments and the additional information provided by Entergy on April 3, 2018 in response to ADEQ's request for more information, ADEQ has determined that a three year compliance time frame is still appropriate for compliance with LSC for Entergy White Bluff and Independence. See Response 20(h).

Comment 33:

Commenters argued that the Proposed SIP is unlawful because it was not reviewed and approved by the Arkansas legislative committees. The commenters asserted that ADEQ's Proposed SIP is plainly a rule within the meaning of Ark. Code Ann. 10-3-309; therefore, ADEQ must submit the Proposed SIP for legislative approval. The commenters argued that ADEQ cannot bypass the legislative approval process by labeling elements of the SIP revision as mere "administrative

⁷⁹ Ark. Code Ann. §§ 4-75-601 *et seq.*

orders” under Ark. Code Ann. 8-4-103(d)(4), which the commenter claimed only applies to civil penalties and to parties that violate provisions of the Chapter 4 of Title 8 of the Arkansas Code and regulations, rules, permits, or plans issued pursuant the Chapter. The commenters pointed out that none of the sources at issue in the administrative orders have violated any provision of Arkansas’s regulations; therefore, the State lacks the authority to invoke Ark. Code Ann. 8-4-103 (d)(4). The commenters state that declaratory orders under Arkansas law pertain to the enforcement or applicability of any rule, not to the establishment of a rule, which the Proposed SIP does. The commenter further argued that Arkansas’s request that EPA withdraw from the SIP currently active Regional Haze Program requirements represents and amendment or repeal of a prior rule, which requires legislative approval without limitation pursuant to Ark. Code Ann. 10-3-309(b)(1)(A).

Response 33:

ADEQ disagrees that the Proposed SIP is unlawful and subject to review and approval under Ark. Code. Ann. § 10-3-309. A SIP is a collection of state provisions that, once approved by EPA, is codified or incorporated by reference into the Code of Federal Regulations in order to meet certain Clean Air Act requirements such as requirements to address visibility under the Regional Haze program. This SIP revision is not subject to legislative approval because neither the state-enforceable legal mechanisms in the administrative orders, nor the federally-enforceable legal mechanisms in the Code of Federal Regulations, are subject to the requirements of Ark. Code. Ann. § 10-3-309.

The Proposed SIP does not require legislative approval under Ark. Code. Ann. § 10-3-309 because each administrative order does not fall within the definition of a “rule.” “Rule” means a state agency statement *of general applicability* and future effect that implements, interprets, or prescribes law or policy or describes the organization, procedure, or practice of a state agency and includes without limitation the amendment or repeal of a prior rule.” Ark. Code. Ann. § 10-3-309 (emphasis added). In this instance, “general applicability” is intended to distinguish a requirement that applies broadly to the public or groups of people or sources of air pollution from those that are intended to be specific an individual entity or facility. The SIP does not set forth any statements or requirements of general applicability to multiple facilities or categories of facilities, but instead each requirement is specific to an individual facility or entity as set forth in the proposed administrative order.

In addition, the Proposed SIP does not require legislative approval under Ark. Code. Ann. § 10-3-309 because the statutory construction of provisions pertaining to SIPs exhibits an intent on the part of the Arkansas legislature to create a separate and distinct set of requirements for SIPs.

Both the definition of the SIP and the roles assigned to ADEQ and the APC&EC indicate that a SIP is not a rule. Subchapter 3 of the Water and Air Pollution Control Act provides the following definition of a SIP: “a plan that specifies measures to be used in the implementation of the state’s

duties under the Clean Air Act, 42 U.S.C. § 7401 et seq., and that is *developed by the [D]epartment and submitted to the United States Environmental Protection Agency* for review and approval.” Ark. Code Ann. § 8-4-303 (emphasis added). Unlike a rule, a SIP is defined as a “plan,” and it is developed by ADEQ rather than the APC&EC. A rule promulgated under the Water and Air Pollution Control Act must be promulgated by the APC&EC.⁸⁰

More detailed requirements for SIPs are set forth in Ark. Code Ann. § 8-4-317, which prescribes a distinct appeals process from that of a rule. Commenters on SIP revisions have “standing to appeal the final *decision of the [D]epartment* to the [APC&EC] upon written application.”⁸¹ An appeal of a SIP “shall be processed *as a permit appeal* under § 8-4-205.” *Id.* ADEQ may “raise all relevant issues of regulatory concern upon adjudicatory review by the [APC&EC].” *Id.*

In addition, ADEQ disagrees that the Proposed SIP constitutes “the amendment or repeal of a prior rule.” The Proposed SIP includes a request for EPA to take certain action including the withdrawal of certain previous provisions of included in the SIP. If EPA chose to take those actions, they would be performed in an action published in the Federal Register, which modifies the Code of Federal regulations provisions that constitute the Arkansas SIP. ADEQ itself is not rescinding or repealing any previous requirements. In contrast, ADEQ is requesting that EPA take certain federal actions with regard to federal regulations. ADEQ’s request for EPA to modify the SIP does not constitute a rule because the request is not a statement of general applicable and future effect. ADEQ’s proposed request, which ADEQ is removing from the final SIP, to withdraw certain provisions from the SIP has no “effect” unless and until EPA takes an altogether separate action modifying federal law. EPA’s actions in withdrawing provisions from the Arkansas SIP are not subject to Ark. Code. Ann. § 10-3-309 because EPA does not fall within the definition of “state agency.” (“State agency” means an office, board, commission, department, council, bureau, or other agency *of state government* having authority to promulgate or enforce rules.) (emphasis added). ADEQ is not proposing in this action to take any action with regard to the state regional haze requirements set forth in APC&EC Reg. 19.1501–19.1507.

ADEQ disagrees with the commenters that it is relying on Ark. Code. Ann. § 8-4-103, which pertains to ADEQ’s authority to issue penalties. ADEQ is not relying on authority set forth in Ark. Code. Ann. § 8-4-103 in the promulgation of the Proposed SIP, but instead ADEQ is relying on the authority provided to it in Ark. Code Ann. § 8-4-311. Ark. Code Ann. § 8-4-311 states that ADEQ has the authority to “[m]ake, issue, modify, revoke, and enforce orders prohibiting, controlling, or abating air pollution.” In addition, ADEQ is provided with the authority to “[d]evelop and implement state implementation plans.” ADEQ is relying on these and other powers delineated in Arkansas statutes in the issuance of these administrative orders in support of its Proposed SIP.

⁸⁰ Ark. Code Ann. § 8-4-202

⁸¹ Ark. Code Ann. § 8-4-317

Similarly, other statutes do not require ADEQ to submit the Proposed SIP for legislative review. Ark. Code Ann. § 8-4-317, which sets forth specific requirements for SIPs, does not require any form of legislative approval. Instead, this statute set forth notice and comment requirements and a method for commenters to appeal Final SIPs to the APC&EC.

Comment 34:

One commenter stated that ADEQ should work with State and local areas to get the most up-to-date equipment and only work with facilities that do the same.

Response 34:

ADEQ must work within the framework of its regulatory authority and the requirements for SIPs under the Regional Haze Regulations. ADEQ based emission limits included in the Proposed SIP on reasoned consideration of analyses of feasible retrofit technologies for subject-to-BART facilities. The factors assessed in these analyses are mandated by statute.⁸² In addition, ADEQ assessed in accordance with factors required by statute whether any additional controls are needed for reasonable progress during the 2008–2018 planning period.⁸³ Emission limits based on control equipment were established within the framework of Clean Air Act 169A, EPA’s Regional Haze Regulations, and EPA guidance for the first Regional Haze planning period.

This comment does not necessitate changes to the Proposed SIP.

Comment 35:

Some commenters submitted comments on the Proposed SIP that were directed toward parties other than ADEQ.

Some commenters questioned Entergy’s choices with respect to management of coal plants. Commenters exhorted power plants to be responsible and stop polluting.

One commenter called on EPA to prove that air quality is its new focus. Some commenters encouraged teamwork in making decisions that will save lives and keep companies from muddying up the air and water. One commenter also stated that Corporate America should play a part for clean air.

Response 35:

⁸² Clean Air Act Section 169A(g)(2) states that in determining BART, the State shall “take into consideration the costs of compliance, the energy and nonair quality environmental impact of compliance, an existing pollution control technology in use at the source, the remaining useful life of the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.”

⁸³ Clean Air Act Section 169A(g)(1) states that “in determining reasonable progress there shall be taken into consideration the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements.”

The comments summarized in Comment 35 were not directed at ADEQ or any specific provision, requirement, or evaluation contained in the Proposed SIP. This comment does not necessitate changes to the Proposed SIP.

Comment 36:

Some commenters demanded that selective catalytic reduction be required for Entergy coal plants. Commenters asserted that this technology has been around for twenty years and ADEQ should know about this technology that prevents pollution.

Response 35:

ADEQ did not include in the Proposed SIP any changes to previous determinations with respect to NO_x for subject-to-BART EGUs and reasonable progress. See Response 9. This comment does not necessitate changes to the Proposed SIP.

3.0 MODEL PERFORMANCE EVALUATION..... 3-1

3.1 Evaluation Methodology..... 3-1

3.2 Operational Model Evaluation Approach 3-2

3.3 Model Performance Goals and Criteria 3-2

3.4 Key Measures of Model Performance 3-2

3.5 Operational Model Performance Evaluation 3-4

 3.5.1 Sulfate (SO₄) Model Performance..... 3-4

 3.5.2 Nitrate (NO₃) Model Performance 3-4

 3.5.3 Organic Matter Carbon (OMC) Model Performance..... 3-5

 3.5.4 Elemental Carbon (EC) Model Performance 3-9

 3.5.5 Other PM_{2.5} (Soil) Model Performance 3-9

 3.5.6 Coarse Mass (CM) Model Performance 3-9

3.6 Diagnostic Model Performance Evaluation 3-13

 3.6.1 Diagnostic Model Performance in January 2002..... 3-13

 3.6.2 Diagnostic Model Performance In April..... 3-16

 3.6.3 Diagnostic Model Performance In July 3-16

 3.6.4 Diagnostic Model Performance In October 3-17

3.7 Performance at CENRAP Class I Areas for the Worst and Best 20 Percent Days.. 3-17

 3.7.1 Caney Creek (CACR) Arkansas 3-17

 3.7.2 Upper Buffalo (UPBU) Arkansas 3-19

 3.7.3 Breton Island (BRET), Louisiana 3-20

 3.7.4 Boundary Waters (BOWA), Minnesota..... 3-21

 3.7.5 Voyageurs (VOYA) Minnesota 3-22

 3.7.6 Hercules Glade (HEGL) Missouri 3-23

 3.7.7 Mingo (MING) Missouri 3-24

 3.7.8 Wichita Mountains (WIMO), Oklahoma..... 3-25

 3.7.9 Big Bend (BIBE) Texas 3-26

 3.7.10 Guadalupe Mountains (GUMO) Texas..... 3-27

3.8 Model Performance Evaluation Conclusions..... 3-28

4.0 VISIBILITY PROJECTIONS..... 4-1

4.1 Guidance for Visibility Projections 4-1

4.2 Calculation of Visibility and 2018 URP Point from IMPROVE Measurements..... 4-2

 4.2.1 Calculation of Visibility from IMPROVE PM Measurements..... 4-3

 4.2.1.1 Original and New IMPROVE Equations..... 4-5

 4.2.1.1.1 Original IMPROVE Equation..... 4-5

 4.2.1.1.2 New IMPROVE Equation..... 4-6

 4.2.1.1.3 Justification for Using the New IMPROVE Equation..... 4-7

 4.2.2 Calculation of the Baseline Conditions..... 4-8

 4.2.3 Data Filling for Sites with Insufficient Valid Data to Calculate Baseline Conditions 4-8

 4.2.4 Natural Conditions 4-8

 4.2.5 2018 URP Point 4-9

4.3 EPA Default Approach to Visibility Projections 4-9

4.3.1	Mapping of Modeling Results to the IMPROVE Measurements	4-10
4.3.2	Using Modeling Results to Project Changes in Visibility	4-11
4.4	EPA Default 2018 Visibility at CENRAP and Nearby Class I areas and Comparisons to 2018 URP Goals	4-12
4.4.1	Example 2018 Base G Visibility Projections for Caney Creek, Arkansas	4-12

1.0 INTRODUCTION

This Technical Support Document (TSD) describes the Central Regional Air Planning Association (CENRAP) regional emissions and air quality modeling to support the central states Regional Haze Rule (RHR) State Implementation Plans (SIPs). The CENRAP 2002 annual emissions and air quality modeling was performed by the contractor team of ENVIRON International Corporation (ENVIRON) and the University of California at Riverside (UCR).

1.1 Background

The 1977 Clean Air Act Amendments (CAAA) added a new Section 169A for the protection of visibility in Federal Class I areas (specific national parks, wilderness areas and wildlife refuges). Section 169A(a)(1) of the CAAA established the national goal for visibility protection: “Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution.” The CAAA require States to submit SIPs containing emission limits, schedules of compliance and to “promulgate regulations to assure reasonable progress toward meeting the national goal” (Section 169A(a)(4)). In response to these mandates EPA promulgated the Regional Haze Rule (RHR) on July 1, 1999 that requires States to “establish goals (expressed in deciviews) that provide for reasonable progress towards achieving natural visibility conditions” at Class I areas. The States’ RHR SIPs are due December 17, 2007 and an important component of the SIP will be the 2018 Reasonable Progress Goals (RPGs) toward achieving natural conditions in 2064. Regional air quality models are used to project visibility to 2018 to determine the level of visibility improvement that is expected to be achieved in 2018. This information, along with other sources, can be used by the states to assist in setting their 2018 RPGs.

CENRAP is one of five Regional Planning Organizations (RPOs) that have responsibility for coordinating development of SIPs and Tribal Implementation Plans (TIPs) in selected areas of the U.S. to address the requirements of the RHR. CENRAP is a regional partnership of states, tribes, federal agencies, stakeholders and citizen groups established to initiate and coordinate activities associated with the management of regional haze and other air quality issues within the CENRAP states. The CENRAP region includes states and tribal lands located within the boundaries of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma and Texas.

The CENRAP Emissions and Air Quality Modeling Team is composed of staff from ENVIRON and UCR, with assistance and coordination from the CENRAP states, tribes, federal agencies and stakeholders. The ENVIRON/UCR Team performs the emissions and air quality modeling simulations for states and tribes within the CENRAP region, providing analytical results used in developing implementation plans under the RHR. Figure 1-1 shows the states included in each of the five RPOs in the U.S., including CENRAP. Table 1-1 lists the Class I areas within the CENRAP states.

CENRAP is performing emissions and air quality modeling to project visibility to 2018. The modeling results will be used to determine the level of visibility improvement expected in 2018

under various emission scenarios. States will use these results to assist in determining their 2018 RPGs toward achieving natural conditions in 2064.

Figure 1-1. Regional Planning Organizations engaged in Regional Haze Modeling.

Table 1-1. Federal Mandated Class I Areas in the CENRAP States.

Class I Area	Acreage	Federal Land Manager	Public Law
Arkansas			
Caney Creek Wilderness Area	14,460	USDA-FS	93-622
Upper Buffalo Wilderness Area	12,018	USDA-FS	93-622
Louisiana			
Breton Wilderness Area	5,000+	USDI-FWS	93-632
Minnesota			
Boundary Waters Canoe Area Wilderness	810,088	USDA-FS	99-577
Voyageurs National Park	114,964	USDI-NP	99-261
Missouri			
Hercules-Glade Wilderness Area	12,314	USDA-FS	94-557
Mingo Wilderness Area	8,000	USDI-FWS	95-557
Oklahoma			
Wichita Mountains Wilderness	8,900	USDI-FWS	91-504
Texas			
Big Bend National Park	708,118	USDI-NP	74-157
Guadalupe Mountains National Park	76,292	USDI-NP	89-667

1.2 CENRAP Organizational Structure and Work Groups

The governing body of CENRAP is the Policy Oversight Group (POG) that is made up of voting members representing states and tribes within the CENRAP region and non-voting members representing local agencies, the EPA and other federal agencies. The work of CENRAP is accomplished through five standing workgroups:

- Monitoring;
- Emissions Inventory;
- Modeling;
- Communications; and
- Implementation and Control Strategies.

Participation in workgroups is open to all interested parties and the POG may form additional ad hoc workgroups to address specific issues (e.g., a Data Analysis workgroup was formed).

The RHR requires the states, and the tribes that may elect to, submit the first SIPs and TIPs that address progress toward natural conditions at federally mandated Class I areas by December 17, 2007. 40 CFR 51.308 (Section 308) discusses the following four core requirements to be included in SIPs/TIPs and Best Available Retrofit Technology (BART) requirements:

1. Reasonable progress goals;
2. Calculations of baseline and natural visibility conditions;
3. A Long-term strategy for regional haze;
4. A Monitoring strategy and other implementation plan requirements; and
5. BART requirements for regional haze visibility impairment.

September 2007

One of CENRAP's goals is to provide support to states and tribes to meet each of these requirements of the RHR and to develop scientifically supportable, economical and effective control strategies that the states and tribes may adopt to reduce anthropogenic effects on visibility impairment at Class I areas. One component of CENRAP's support to states and tribes as part of compliance with the RHR is performing emissions and air quality modeling. These activities were implemented to:

- obtain a better understanding of the causes of visibility impairment and to identify potential mitigation measures for visibility impairment at Class I areas;
- to evaluate the effects of alternative control strategies for improving visibility; and
- to project future-year air quality and visibility conditions.

In October 2004, CENRAP selected the team of ENVIRON and UCR to perform their Emissions and Air Quality Modeling.

The CENRAP Emissions and Air Quality Modeling Team performs regional haze analyses by operating regional scale, three-dimensional air quality models that simulate the emissions, chemical transformations, and transport of gaseous and particulate matter (PM) species and consequently the effects on visibility in Class I Areas in the central U.S. A key element of this work includes the integration of emissions inventories and emissions models with regional transport models. The general services provided by the CENRAP Emissions and Air Quality Modeling Team include, but are not limited to:

- Emissions processing and modeling;
- Air quality and visibility modeling simulations;
- Analysis, display, and reporting of modeling results; and
- Storage/quality assurance of the modeling input and output files.

The CENRAP 2002 annual Emissions and Air Quality Modeling Team performs work for the CENRAP Modeling Workgroup through direction from the CENRAP Technical Director and CENRAP Executive Director.

1.3 Overview of 2002 Annual Emissions and Air Quality Modeling Approach

The CENRAP 2002 annual emissions and air quality modeling was initiated on October 16, 2004 and involved the preparation of numerous databases, model simulations, presentations and reports. Much of the modeling analyses have been posted to the CENRAP modeling website at: <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>. There were numerous versions and iterations of the modeling and interim results. The results presented in this TSD focus on the final modeling results and key findings in their development. The reader is referred to the modeling website for interim products.

1.3.1 Modeling Protocol

A Modeling Protocol was prepared at the outset of the study to serve as a road map for performing the CENRAP emissions and air quality modeling and to communicate the modeling

plans to the CENRAP participants. The Modeling Protocol was prepared following EPA guidance for preparation at the time it was prepared (EPA, 1991; 1999, 2001) and took into account CENRAP's long-term plan (CENRAP, 2003) and the modeling needs of the RHR SIPs. The first version (Version 1.0) of the Modeling Protocol was dated November 19, 2004. Based on comments received from CENRAP, the Modeling Protocol was updated to the current Version 2.0 (Morris et al., 2004a) that was dated December 8, 2004. This Modeling Protocol can be found on the CENRAP modeling Website at:

http://pah.cert.ucr.edu/aqm/cenrap/docs/CENRAP_Draft2.0_Modeling_Protocol_120804.pdf

1.3.2 Quality Assurance Project Plan (QAPP)

A Quality Assurance Project Plan (QAPP) was prepared for the CENRAP emissions and air quality modeling study that described the quality management functions performed by the modeling team. The QAPP was prepared and was based on the national consensus standards for quality assurance (ANSI/ASQC, 1994), followed EPA's guidelines for quality assurance project plans for modeling (EPA, 2002) and for QAPPs (EPA, 2001) and took into account the recommendations from the North American Research Strategy for Tropospheric Ozone (NARSTO) Quality Handbook for modeling projects (NARSTO, 1998). The EPA and NARSTO guidance documents were developed specifically for modeling projects, which have different quality assurance concerns than environmental monitoring data collection projects. The work performed in this project involves modeling at the basic research level and for regulatory/planning applications. In order to use model outputs for these purposes, it must be established that each model is scientifically sound, robust, and defensible. This is accomplished by following a project planning process that incorporates the following elements as described in the EPA modeling guidance document:

- A systematic planning process including identification of assessments and related performance criteria;
- Peer reviewed theory and equations;
- A carefully designed life-cycle development process that minimizes errors;
- Documentation of any changes from original plans;
- Clear documentation of assumptions, theory, and parameterization that is detailed enough so others can understand the model output;
- Input data and parameters that are accurate and appropriate for the analysis; and
- Output data that can be used to help inform decision makers.

The CENRAP QAPP can be found at:

http://pah.cert.ucr.edu/aqm/cenrap/docs/CENRAP_QAPP_Nov_24_2004.pdf.

A key component of the CENRAP emissions and air quality modeling QAPP was the graphical display of model inputs and outputs and multiple peer-review of each step of the modeling process. This was accomplished through use of the CENRAP modeling website where modelers posted displays of work products (e.g., emissions plots, model outputs, etc.) for review by the CENRAP modeling team, modeling workgroup and others. This website can be found at: <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>.

1.3.3 Model Selection

The selection of the meteorological, emissions and air quality models for the CENRAP regional haze modeling was based on a review of previous regional haze modeling studies performed in the CENRAP region (e.g., Pitchford et al., 2004; Pun, Chen and Seigneur, 2004; Tonnesen and Morris 2004) as well as elsewhere in the United States (e.g., Morris et al, 2004a; Tonnesen et al., 2003; Baker, 2004). The CENRAP emissions and air quality Modeling Protocol (Morris et al., 2004a) provides details on the justification for model selection and the formulation of the different models. Based on previous work (e.g., CENRAP, WRAP, VISTAS, MRPO, BRAVO and EPA), CENRAP selected the following models for use in modeling PM and regional haze in the central states:

- **MM5:** The Pennsylvania State University/National Center for Atmospheric Research (PSU/NCAR) Mesoscale Meteorological Model (MM5 Version 3.6 MPP) is a non-hydrostatic, prognostic meteorological model routinely used for urban- and regional-scale photochemical, fine particulate, and regional haze regulatory modeling studies (Anthes and Warner, 1978; Chen and Dudhia, 2001; Stauffer and Seaman, 1990, 1991; Xiu and Pleim, 2000).
- **SMOKE:** The Sparse Matrix Operator Kernel Emissions (SMOKE) modeling system is an emissions modeling system that generates hourly gridded speciated emission inputs of mobile, non-road, area, point, fire and biogenic emission sources for photochemical grid models. (Coats, 1995; Houyoux and Vukovich, 1999). As with most 'emissions models', SMOKE is principally an *emission processing system* and not a true *emissions modeling system* in which emissions estimates are simulated from 'first principles'. This means that, with the exception of mobile and biogenic sources, its purpose is to provide an efficient tool for converting an existing base emissions inventory data into the hourly, gridded, speciated, and formatted emission files required by an air quality model.
- **CMAQ:** EPA's Models-3/Community Multiscale Air Quality (CMAQ) modeling system is a 'One-Atmosphere' photochemical grid model capable of addressing ozone, PM, visibility and acid deposition at a regional scale for extended periods of time (Dennis, et al., 1996; Byun et al., 1998a; Byun and Ching, 1999, Pleim et al., 2003).
- **CAMx:** ENVIRON's Comprehensive Air Quality Model with Extensions (CAMx) modeling system is also a state-of-science 'One-Atmosphere' photochemical grid model capable of addressing ozone, PM, visibility and acid deposition at a regional scale for extended periods of time. (ENVIRON, 2006).

1.3.3.1 MM5 Meteorological Model Configuration for CENRAP Annual Modeling

Application of the MM5 for the 2002 annual modeling on a 36 km grid for the continental US was performed by the Iowa Department of Natural Resources (IDNR; Johnson, 2007). Details of the 2002 36 km MM5 model application and evaluation procedures carried out by IDNR may be found in Johnson, 2007. Application of the MM5 model on a 12 km grid covering the Central States for portions of 2002 was performed by EPA Region VII and the Texas Commission on Environmental Quality (TCEQ).

The MM5 (Version 3.63) configuration used in the generation of the meteorological modeling datasets consists of the following (see Table 1-2 for more details):

- 36 km grid with 34 vertical layers;
- 12 km nested grid for episodic modeling;
- For 12 km runs use two way nesting (without feedback) within the 36 km grid;
- Initialization and boundary conditions from Eta analysis fields;
 - Eta 3D and surface analysis data (ds609.2);
 - Not using NCEP global tropospheric SST data (ds083.0) ;
 - Observational enhancement (LITTLE_R)
 - NCEP ADP surface obs (ds464.0)
 - NCEP ADP upper-air obs (ds353.4)
- Pleim-Xiu (P-X) land-surface model (LSM);
- Pleim-Chang Asymmetric Convective Mixing (ACM) PBL model;
- Kain-Fritsch 2 cumulus parameterization;
- Mixed phase (Reisner 1) cloud microphysics;
- Rapid Radiative Transfer Model (RRTM) radiation;
- No Shallow Convection (ISHALLO=0);
- Standard 3D FDDA analysis nudging outside of PBL; and
- Surface nudging of the winds only.

1.3.3.2 SMOKE Emissions Model Configuration for CENRAP Annual Modeling

SMOKE supports area, mobile, fire and point source emission processing and includes biogenic emissions modeling through a rewrite of the Biogenic Emission Inventory System, version 3 (BEIS3) (see, <http://www.epa.gov/ttn/chief/software.html#pcbeis>). SMOKE has been available since 1996, and has been used for emissions processing in a number of regional air quality modeling applications. In 1998 and 1999, SMOKE was redesigned and improved with the support of the U.S. Environmental Protection Agency (EPA), for use with EPA's Models-3/CMAQ (<http://www.epa.gov/asmdnerl/models3>). The primary purposes of the SMOKE redesign were support of: (a) emissions processing with user-selected chemical mechanisms and (b) emissions processing for reactivity assessments.

As an emissions processing system, SMOKE has far fewer 'science configuration' options compared with the MM5 and CMAQ models. Table 1-3 summarizes the version of the SMOKE system that was used and the sources of data that were employed in constructing the required modeling inventories.

1.3.3.3 CMAQ Air Quality Model Configuration for CENRAP Annual Modeling

CENRAP used CMAQ Version 4.5 with the "SOAmods enhancement", described below, and used the model configuration as shown in Table 1-4. The model was set up and exercised on the same 36 km grid that was used by WRAP and VISTAS, the 36 km RPO national grid. CENRAP performed 12 km CMAQ sensitivity tests and found little change in model performance with a large penalty in computation time. Consequently, at the February 7, 2006 CENRAP Modeling

Workgroup Meeting a decision was made to proceed with the CENRAP emissions and air quality modeling using just the 36 km national RPO grid (Morris et al., 2006a).

Initial CMAQ 2002 simulations performed by VISTAS found that the model greatly underestimates organic mass carbon (OMC) concentrations, especially in the summer. A review of the CMAQ formulation found that it failed to treat Secondary Organic Aerosol (SOA) formation from sesquiterpenes and isoprene and also failed to account for the fact that SOA can become polymerized so that it is no longer volatile and stays in the particle form. Thus, VISTAS updated the CMAQ SOA module to include these missing processes and found much improved OMC model performance (Morris et al., 2006c). CENRAP tested the CMAQ Version 4.5 with SOAmods enhancement and found it performed much better for OMC than the standard versions of CMAQ Version 4.5. Therefore, CMAQ Version 4.5, with the enhanced SOAmods (Morris et al., 2006c), was adopted for the CENRAP modeling. CMAQ Version 4.5 is available from the CMAS center (www.cmascenter.org).

1.3.3.4 CAMx Air Quality Model Configuration for CENRAP Annual Modeling

CAMx Version 4.40 was applied using similar options as used by CMAQ. CAMx was used initially in side-by-side comparisons with CMAQ. Comparative model performance results and other factors for CAMx V4 and CMAQ V4.4 with SOAmods were presented at the February 7, 2006 CENRAP modeling workgroup meetings that found (Morris et al., 2006b):

- No one model was consistently performing better than the other over all species and averaging times.
- Both models performed well for sulfate.
- CMAQ's winter nitrate over-prediction tendency not as large as CAMx's.
- CAMx performed slightly better than CMAQ for elemental carbon (EC).
- CMAQ performed much better than CAMx for organic mass carbon (OMC).
- Both models over-predicted Soil and under-predicted coarse mass (CM).
- CMAQ ran faster than CAMx due to MPI multi-processing capability.
- CAMx required much less disk space than CMAQ.

Based on these factors, CMAQ was selected as the lead air quality model for the CENRAP regional haze modeling with CAMx the secondary corroborative model. However, CAMx also contained a PM Source Apportionment Technology (PSAT) capability that was used widely in the CENRAP modeling. Table 1-4 lists the main CAMx configuration used for the CENRAP annual modeling that was selected, in part, to be consistent with the CMAQ model configuration (Table 1-4). One exception to this was that the CAMx PSAT simulations used the Bott advection solver rather than the PPM advection solver. The PPM advection solver is typically used in the standard CAMx and CMAQ runs. Bott, however, is more computationally efficient and the high computational requirements of the CAMx PSAT runs dictated this choice.

Table 1-2. MM5 Meteorological Model Configuration for CENRAP 2002 Annual Modeling (Johnson, 2007).

Science Options	Configuration	Details/Comments
Model Code	MM5 version 3.63	Grell et al., 1994
Horizontal Grid Mesh	36 km	
36 km grid	165 x 129 dot points	RPO MM5 Grid
Vertical Grid Mesh	34 layers	Vertically varying; sigma pressure coordinate system
Grid Interaction	No Feedback	IFEED=0
Initialization	Eta first guess fields/LittleR	
Boundary Conditions	Eta first guess fields/LittleR	
Microphysics	Reisner I Mixed Ice	Look up table
Cumulus Scheme	Kain-Fritsch 2	On 36 and 12 km Grids
Planetary Boundary Layer	ACM PBL

1.3.4 Modeling Domains

The CENRAP emissions and air quality modeling was conducted on the 36 km national RPO domain as depicted in Figure 1-2. This domain consists of a 148 by 112 array of 36 km by 36 km grid cells and covers the continental United States. Sensitivity simulations were also performed for episodes on a 12 km modeling domain covering the central states, however the results were very similar to the 36 km results so CENRAP elected to proceed with the 2002 annual modeling using the 36 km domain for computational efficiency (Morris et al., 2006a).

Figure 1-2. National Inter-RPO 36 km modeling domain used for the CENRAP 2002 annual SMOKE, CMAQ and CAMx modeling.

1.3.5 Vertical Structure of Modeling Domain

The MM5 meteorological model was exercised using 34 vertical layers from the surface to a pressure level of 100 mb (approximately 15 km above ground level). Both the CMAQ and CAMx air quality models can employ layer collapsing in which vertical layers in the MM5 are combined in the air quality model, which improves computational efficiency. The sensitivity of the CMAQ model estimates to the number of vertical layers was evaluated by the Western Regional Air Partnership (WRAP) and Visibility Improvements State and Tribal Association of the Southeast (VISTAS) (Tonnesen et al., 2005; 2006; Morris et al., 2004a). CMAQ model simulations were performed with no layer collapsing (i.e., the same 34 layers as used by MM5) and with various levels of layer collapsing. These studies found that using 19 vertical layers up

to 100 mb (i.e., same model top as MM5) and matching the eight lowest MM5 vertical layers near the surface produced nearly identical results as with no layer collapsing. They also found that very aggressive layer collapsing (e.g., 34 to 12 layers) produced results with substantial differences compared to no layer collapsing. Therefore, based on the WRAP/VISTAS sensitivity analysis, CENRAP adopted the 19 vertical layer configuration up to the 100 mb model top. Figure 1-3 displays the definition of the 34 MM5 vertical layers and how they were collapsed to 19 vertical layers in the air quality modeling performed by CENRAP.

MM5					CMAQ 19L				
Layer	Sigma	Pres(mb)	Height(m)	Depth(m)	Layer	Sigma	Pres(mb)	Height(m)	Depth(m)

Figure 1-3. MM5 34 vertical layer definitions and scheme for collapsing the 34 layers down to 19 layers for the CENRAP CMAQ and CAMx 2002 annual modeling.

1.3.6 2002 Calendar Year Selection

The calendar year 2002 was selected for CENRAP regional haze annual modeling as described in the CENRAP Modeling Protocol (Morris et al., 2004a). EPA's applicable guidance on PM_{2.5}/Regional Haze modeling at that time (EPA, 2001) identified specific goals to consider when selecting modeling periods for use in demonstrating reasonable progress in attaining the regional haze goals. However, since there is much in common with the goals for selecting episodes for annual and episodic PM_{2.5} attainment demonstrations as well as regional haze, EPA's current guidance addresses all three in a common document. (EPA, 2007) At the time of the modeling period selection EPA had also published an updated summary of PM_{2.5} and Regional Haze Modeling Guidance (Timin, 2002) that served, in some respects, as an interim placeholder until the final guidance was issued as part of the PM_{2.5}/regional haze NAAQS implementation process that was ultimately published in April 2007 (EPA, 2007). The interim EPA modeling guidance for episode selection (EPA, 2001; Timin, 2002) was consistent with the final EPA regional haze modeling guidance (EPA, 2007).

EPA recommends that the selection of a modeling period derive from three principal criteria:

- A variety of meteorological conditions should be covered that includes the types of meteorological conditions that produce the worst 20 percent and best 20 percent visibility days at Class I areas in the CENRAP States during the 2000-2004 baseline period;
- To the extent possible, the modeling data base should include days for which enhanced data bases (i.e. beyond routine aerometric and emissions monitoring) are available; and
- Sufficient days should be available such that relative response factors (RRFs) can be based on several (i.e., ≥ 15) days.

For regional haze modeling, the guidance goes further by suggesting that the preferred approach is to model a full, *representative* year (EPA, 2001, pg. 188). Moreover, the required RRF values should be based on model results averaged over the 20 percent worst and 20 percent best visibility days determined for each Class I area based on monitoring data from the 2000 – 2004 baseline period. More recent EPA guidance (Timin, 2002) suggests that states should model at least 10 worst and 10 best visibility days at each Class 1 area. EPA also lists several 'other considerations' to bear in mind when choosing potential PM/regional haze episodes including: (a) choose periods which have already been modeled, (b) choose periods which are drawn from the years upon which the current design values are based, (c) include weekend days among those chosen, and (d) choose modeling periods that meet as many episode selection criteria as possible in the maximum number of nonattainment or Class I areas as possible.

Due to limited available resources CENRAP was restricted to modeling a single calendar year. The RHR uses the five-year baseline of 2000-2004 period as the starting point for projecting future-year visibility. Thus, the modeling year should be selected from this five-year baseline period. The 2002 calendar year, which lies in the middle of the 2000-2004 Baseline, was selected for the following reasons:

- Based on available information, 2002 appears to be a fairly typical year in terms of meteorology for the 5-year Baseline period of 2000-2004;

- 2003 and 2004 appeared to be colder and wetter than typical in the eastern US;
- The enhanced IMPROVE and IMPROVE Protocol and Supersites PM monitoring data were fully operational by 2002. Much less IMPROVE monitoring data was available during 2000-2001, especially in the CENRAP region;
- IMPROVE data for 2003 and 2004 were not yet available at the time that the CENRAP modeling was initiated; and
- 2002 was being used by the other RPOs.

1.3.7 Initial Concentrations and Boundary Conditions

The CMAQ and CAMx models were operated separately for each of four quarters of the 2002 year using a ~15 day spin up period (i.e., the models were started approximately 15 days before the first day of interest in each quarter in order to limit the influence of the assumed initial concentrations, e.g., start June 15 for quarter 3 whose first day of interest is July 1). Sensitivity simulations demonstrated that with ~15 initialization days, the influence of initial concentrations (ICs) was minimal using the 36 km Inter-RPO continental U.S. modeling domain. Consequently, clean ICs were specified in the CMAQ and CAMx modeling using a ~15 day spin up period.

Boundary Conditions (BCs) (i.e., the assumed concentrations along the later edges of the 36 km modeling domain, see Figure 1-2) were based on a 2002 simulation by the GEOS-CHEM global circulation/chemistry model. GEOS-CHEM is a three-dimensional global chemistry model driven by assimilated meteorological observations from the Goddard Earth Observing System (GEOS) of the [NASA Global Modeling and Assimilation Office](#). It is applied by [research groups around the world](#) to a wide range of atmospheric composition problems, including future climates and planetary atmospheres using general circulation model meteorology to drive the model. Central [management and support](#) of the model is provided by the [Atmospheric Chemistry Modeling Group](#) at Harvard University.

A joint RPO study was performed, coordinated by VISTAS, in which Harvard University applied the GEOS-CHEM global model for the 2002 calendar year (Jacob, Park and Logan, 2005). The University of Houston (UH) was retained to process the 2002 GEOS-CHEM output into BCs for the CMAQ model (Byun, 2004). The GEOS-CHEM simulations for the RPOs used GEOS meteorological observations for the year 2002. These were obtained from the Global Modeling and Assimilation Office (GMAO) as a 6-hourly archive (3-hour for surface quantities such as mixing depths). The data through August 2002 were from the GEOS-3 assimilation, with horizontal resolution of $1^{\circ} \times 1^{\circ}$ and 55 vertical layers. The data after August 2002 were from the updated GEOS-4 assimilation, with horizontal resolution of $1^{\circ} \times 1.25^{\circ}$ and 48 vertical layers (note 1° latitude is equal to approximately 110 km). The GEOS-CHEM output was processed by mapping the GEOS-CHEM chemical compounds to the species in the CBM-IV chemical mechanism used by CMAQ/CAMx and mapping the GEOS-CHEM vertical layers to the 19 layer vertical layer structure used by CMAQ/CAMx in the CENRAP modeling (Byun, 2004). The results were day-specific three-hourly BC inputs for the CMAQ model. The CMAQ2CAMx processor was then used to transform the CMAQ day-specific 3-hourly BCs to the format used by CAMx.

There were several quality assurance (QA) checks of the BCs generated from the 2002 GEOS-CHEM output. The first QA/QC check was a range check to assure reasonable values. The BCs were compared against the GEOS-CHEM outputs to assure the mapping and interpolation was performed correctly. The code used to map the GEOS-CHEM output to the CMAQ BC format was obtained from UH, reviewed and the BC generation duplicated for several time periods during 2002.

1.3.8 Emissions Input Preparation

The CENRAP SMOKE emissions modeling was based on an updated 2002 emissions data for the U.S. (Pechan, 2005c,e; Reid et al., 2004a,b), 1999 emissions data for Mexico (ERG, 2006), and 2000 emissions data for Canada. These data were used to generate a final base 2002 Base G Typical (Typ02G) annual emissions database. Numerous iterations of the emissions modeling were conducted using interim databases before arriving at the final Base G emission inventories (e.g., Morris et al., 2005). The 2018 Base G base case emissions (Base18G) for most source categories in the U.S. were based on projections of the 2002 inventory assuming growth and control (Pechan, 2005d). 2018 EGU emissions were based on the run 2.1.9 of the Integrated Planning Model (IPM) updated by the CENRAP states. Canadian emissions for the Base18G scenario were based on a 2020 inventory, whereas the Mexican 1999 inventory was held constant for 2018.

The Typ02G and Base18G emission inventories represent significant improvements to the preliminary emissions modeling performed by CENRAP (Morris et al., 2005). While the preliminary 2002 modeling served its purpose to develop the infrastructure for modeling large emissions data sets and producing annual emissions simulations, much of the input data (both as inventories and ancillary data) were placeholders for actual 2002 data that were being prepared through calendar year 2005. As these actual 2002 data sets became available, they were integrated into the SMOKE modeling and QA system that was developed during the preliminary modeling, to produce a high-quality emissions data set for use in the final CMAQ and CAMx modeling. The addition of entirely new inventory categories, like marine shipping, added complexity to the modeling. By the end of the emissions data collection phase, there were 23 separate emissions processing streams covering a variety of sources categories necessary to general model-ready emission inputs for the 2002 calendar year.

Details on the emissions modeling are provided in Chapter 2 with additional information contained in Appendix B.

1.3.9 Meteorological Input Preparation

The 2002 36 km MM5 meteorological modeling was conducted by the Iowa Department of Natural Resources (IDNR) who also performed a preliminary model performance evaluation (Johnson, 2007). CENRAP performed an additional MM5 evaluation of the CENRAP 2002 36 km MM5 simulation that included a comparative evaluation against the final VISTAS 2002 36 km MM5 and an interim WRAP 2002 36 km simulation (Kemball-Cook et al., 2004). Kemball-Cook and co-workers (2004) found the following in the comparative evaluation of the CENRAP, WRAP and VISTAS 2002 36 km MM5 simulations, (details are provided in Appendix A):

Surface Meteorological Performance within the CENRAP Region

- The three MM5 simulations (CENRAP, VISTAS and WRAP) obtained comparable model performance for winds and humidity that were within model performance benchmarks.
- The WRAP MM5 simulation obtained better temperature model performance than the other two simulations due to the use of surface temperature data assimilation.
 - In the final WRAP MM5 simulation the use of surface temperature assimilation was dropped because it introduced instability in the vertical structure of the atmosphere.
- For all three runs, the Northern CENRAP domain had a cold bias in winter and a warm bias in summer.

Surface Meteorological Performance outside the CENRAP Region

- All three runs had similar surface wind model performance in the western U.S. that was outside the model performance benchmarks
- For temperature, the WRAP MM5 simulation had the best performance overall due to the surface temperature data assimilation that was dropped in the final WRAP run.
- The three runs had comparable humidity performance, although WRAP exhibited a larger wet bias in the summer and the southwestern U.S.

Upper-Air Meteorological Performance

- The VISTAS and CENRAP MM5 simulations were better able to reproduce the deep convective summer boundary layers compared to the WRAP MM5 simulations, which exhibited a smoother decrease in temperature with increase in altitude.
- CENRAP and VISTAS MM5 simulations better simulated the surface temperature inversions than WRAP.
- WRAP was better able to simulate the surface temperature.
- All three models exhibited similar vertical wind profiles.

Precipitation Performance

- In winter, all three MM5 simulations exhibited similar, fairly good, performance in reproducing the spatial distribution and magnitudes of the monthly average observed precipitation.
- In summer, all runs had a wet bias, particularly in the desert southwest where the interim WRAP run had the largest wet bias.

In conclusion, the VISTAS simulation appeared to perform best, the CENRAP MM5 model performance was generally between the VISTAS and WRAP performance, with performance more similar to VISTAS than WRAP. Although the interim WRAP MM5 simulation performed best for surface temperature due to the surface temperature data assimilation, the surface temperature assimilation degraded the MM5 upper-air performance including the ability to assimilate surface inversions and was ultimately dropped from the final WRAP MM5 simulations (Kemball-Cook et al., 2005).

The IDNR 12 km² MM5 simulations were also evaluated and compared with the performance of the 36 km MM5 simulation (Johnson et al., 2007). The IDNR 36 km and 12 km MM5 model performance was similar (Johnson, 2007), which supported the findings of the CMAQ and CAMx 36 and 12 km sensitivity simulations that there was little benefit of using a 12 km grid for simulating regional haze at rural Class I areas (Morris et al., 2006a). However, as noted by Tonnesen and co-workers (2005; 2006) and EPA modeling guidance (1991; 1999; 2001; 2007) this finding does not necessarily hold for 8-hour ozone and PM_{2.5} modeling that is characterized by sharper concentration gradients and frequently occurs in the urban environment as compared to the more rural nature of regional haze.

1.3.10 Photolysis Rates Model Inputs

Several chemical reactions in the atmosphere are initiated by the photodissociation of various trace gases. To accurately represent the complex chemical transformations in the atmosphere, accurate estimates of these photodissociation rates must be made. The Models-3/CMAQ system includes the JPROC processor, which calculates a table of clear-sky photolysis rates (or J-values) for a specific date. JPROC uses default values for total aerosol loading and provides the option to use default ozone column data or to use measured total ozone column data. These data come from the Total Ozone Mapping Spectrometer (TOMS) satellite data. TOMS data that is available at 24-hour averages was obtained from <http://toms.gsfc.nasa.gov/eptoms/ep.html>. Day-specific TOMS data was used in the CMAQ radiation model (JPROC) to calculate photolysis rates. The TOMS data were missing or erroneous for several periods in 2002: August 2-12; June 10; and November 18-19. Thus, the TOMS data for August 1, 2002 was used for August 2-7 and TOMS data for August 13 was used for August 8-12. Similarly, TOMS data for June 9 was used for June 10 and data for August 17 was used for August 18-19. Note that the total column of ozone in the atmosphere is dominated by stratospheric ozone which has very little day-to-day variability so the use of TOMS data within a week or two of an actual day introduces minimal uncertainties in the modeling analysis.

JPROC produces a "look-up" table that provides photolysis rates as a function of latitude, altitude, and time (in terms of the number of hours of deviation from local noon, or hour angle). In the current CMAQ implementation, the J-values are calculated for six latitudinal bands (10°, 20°, 30°, 40°, 50°, and 60° N), seven altitudes (0 km, 1 km, 2 km, 3 km, 4 km, 5 km, and 10 km), and hourly values up to √8 hours of deviation from local noon. During model calculations, photolysis rates for each model grid cell are estimated by first interpolating the clear-sky photolysis rates from the look-up table using the grid cell latitude, altitude, and hour angle, followed by applying a cloud correction (attenuation) factor based on the cloud inputs from MM5.

The photolysis rates input file was prepared as separate look-up tables for each simulation day. Photolysis files are ASCII files that were visually checked for selected days to verify that photolysis are within the expected ranges.

² The IDNR twelve 12 km annual simulation domain was not sufficient for CENRAP's needs, thus Bret Anderson with EPA Region 7 in cooperation with Texas completed an episodic 12km simulation on a larger domain.

The Tropospheric Ultraviolet and Visible (TUV) Radiation Model (<http://cprm.acd.ucar.edu/Models/TUV/>) is used to generate the photolysis rates input file for CAMx. TOMS ozone data and land use data were used to develop the CAMx Albedo/Haze/Ozone input file for 2002. As for CMAQ, the missing TOMS data period in the fall of 2002 was filled-in using observed TOMS data on either side of the missing period using the same procedures as described above for CMAQ. Default land use specific albedo values were used and a constant haze value used, corresponding to rural conditions over North America.

1.3.11 Air Quality Input Preparation

Air quality data used with the CMAQ and CAMx modeling systems include: (1) Initial Concentrations (ICs) that are the assumed initial three-dimensional concentrations throughout the modeling domain.; (2) the Boundary Conditions (BCs) that are the concentrations assumed along the lateral edges of the RPO national 36 km modeling domain; and (3) air quality observations that are used in the model performance evaluation (MPE). The MPE is discussed in Section 3 and Appendix C of this TSD.

As noted in Section 1.3.7, CMAQ default clean Initial Concentrations (ICs) were used along with an approximately 15 day spin up (initialization) period to eliminate any significant influence of the ICs on the modeled concentrations for the days of interest. The same ICs were used with CAMx as well. Both CMAQ and CAMx were run for each quarter of the year. Each quarter’s model run was initialized 15 days prior to the first day of interest (e.g., for quarter 3, Jul-Aug-Sep, the model was initialized on June 15, 2002 with the first modeling day of interest July 1, 2002). The CMAQ Boundary Conditions (BCs) for the Inter-RPO 36 km continental U.S. grid (Figure 1-2) were based on day-specific 3-hour averages from the output of the GEOS-CHEM global simulation model of 2002 (Jacob, Park and Logan, 2005). The 2002 GEOS-CHEM output was mapped to the species and vertical layer structure of CMAQ and interpolated to the lateral boundaries of the 36 km grid shown in Figure 1-2 (Byun, 2004).

Table 1-6 summarizes the surface air quality monitoring networks and the number of sites available in the CENRAP region that were used in the model performance evaluation. Data from these monitoring networks were also used to evaluate the CMAQ and CAMx models outside of the CENRAP region.

Table 1-6. Ground-level ambient data monitoring networks and stations available in the CENRAP states for calendar year 2002 used in the model performance evaluation.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration	Approximate Number of Monitors
IMPROVE	Speciated PM _{2.5} and PM ₁₀	1 in 3 days; 24 hr	11
CASTNET	Speciated PM _{2.5} , Ozone	Hourly, Weekly; 1 hr, 1 Week	3
NADP	WSO ₄ , WNO ₃ , WNH ₄	Weekly	23
EPA-STN	Speciated PM _{2.5}	Varies; Varies	12
AIRS/AQS	CO, NO, NO ₂ , NO _x , O ₃	Hourly; Hourly	25

1.3.12 2002 Base Case Modeling and Model Performance Evaluation

The CMAQ and CAMx models were evaluated against ambient measurements of PM species, gas-phase species and wet deposition. Table 1-6 summarizes the networks used in the model evaluation, the species measured and the averaging times and frequency of the measurements. Numerous iterations of CMAQ and CAMx 2002 base case simulations and model performance evaluations were conducted during the course of the CENRAP modeling study, most of which have been posted on the CENRAP modeling website (<http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml>) and presented in previous reports and presentations for CENRAP (e.g., Morris et al., 2005; 2006a,b). Details on the final 2002 Base F 36 km CMAQ base case modeling performance evaluation are provided in Chapter 3 and Appendix C (because of the similarity between 2002 Base F and 2002 Base G and resource constraints the model evaluation was not re-conducted for Base G). In general, the model performance of the CMAQ and CAMx models for sulfate (SO₄) and elemental carbon (EC) was good. Model performance for nitrate (NO₃) was variable, with a summer underestimation and winter overestimation bias. Performance for organic mass carbon (OMC) was also variable, with the inclusion of the SOAmods enhancement in CMAQ Version 4.5 greatly improving the CMAQ summer OMC model performance (Morris et al., 2006c). Model performance for Soil and coarse mass (CM) was generally poor. Part of the poor performance for Soil and CM is believed to be due to measurement-model incommensurability. The IMPROVE measured values are due, in part, to local fugitive dust sources that are not captured in the model's emission inputs and the 36 km grid resolution is not conducive to modeling localized events.

1.3.13 2018 Modeling and Visibility Projections

Emissions for the 2018 base case were generated following the procedures discussed in Section 1.3.8 and Chapter 2. 2018 emissions for Electrical Generating Units (EGUs) were based on simulations of the Integrated Planning Model (IPM) that took into the account the effects of the Clean Air Interstate Rule (CAIR) on emissions from EGUs in CAIR states using an IPM realization of a CAIR cap-and-trade program. Emissions for on-road and non-road mobile sources were based on activity growth and emissions factors from the EPA MOBILE6 and NONROAD models, respectively. Area sources and non-EGU point sources were grown to 2018 levels (Pechan, 2005d). The Canadian year 2000 emissions inventory was replaced by a Canadian 2020 emissions inventory for the 2018 CMAQ/CAMx simulations. The following sources were assumed to remain constant between the 2002 and 2018 base case simulations:

- Biogenic VOC and NO_x emissions from the BEIS3 biogenic emissions model;
- Wind blown dust associated with non-agricultural sources (i.e., natural wind blown fugitive dust);
- Off-shore emissions associated with off-shore marine and oil and gas production activities;
- Emissions from wildfires;
- Emissions from Mexico; and
- Global transport (i.e., emissions due to BCs from the 2002 GEOS-CHEM global chemistry model.

The results from the 2002 and 2018 CMAQ and CAMx simulations were used to project 2018 PM levels from which 2018 visibility estimates were obtained. The 2002 and 2018 modeling results were used in a relative sense to scale the observed PM concentrations from the 2000-2004 Baseline and the IMPROVE monitoring network to obtain the 2018 PM projections. The 2018/2002 modeled scaling factors are called Relative Response Factors (RRFs) and are constructed as the ratio of modeling results for the 2018 model simulation to the 2002 model simulation. Two important regional haze metrics are the average visibility for the worst 20 percent and best 20 percent days from the 2000-2004 five-year Baseline. For the 2018 visibility projections, EPA guidance recommends developing Class I area and PM species specific RRFs using the average modeling results for the worst 20 percent days during the 2002 modeling period and the 2002 and 2018 emission scenarios. The results of the CENRAP 2018 visibility projections following EPA guidance procedures (EPA, 2007a) are provided in Chapter 4 and Appendix D. CENRAP has also developed alternative procedures for visibility projections that are discussed in Chapter 5 and Appendix D. For example, much of the coarse mass (CM) impacts at Class I area IMPROVE monitors is believed to be natural and primarily from local sources that are subgrid-scale to the modeled 36 km grid so are not represented in the modeling. So, one alternative visibility projection approach is to set the RRF for CM to 1.0. That is, the CM impacts in 2018 are assumed to be the same as in the observed 2000-2004 Baseline. Similarly, the Soil impacts at IMPROVE monitors are likely mainly due to local dust sources so another alternative approach is to set the RRFs for both CM and Soil to 1.0.

The 2018 visibility projections for the worst 20 percent days are compared against a 2018 point on the Uniform Rate of Progress (URP) glidepath or the “2018 URP point”. The 2018 URP point is obtained by constructing a linear visibility glidepath in deciviews from the observed 2000-2004 Baseline (EPA, 2003a) for the worst 20 percent days to the 2064 Natural Conditions (EPA, 2003b; Pitchford, 2006). Where the linear glidepath crosses the year 2018 is the 2018 URP point. States may use the modeled 2018 visibility to help define their 2018 RPG in their RHR SIPs. The 2018 URP point is used as a benchmark to help judge the 2018 modeled visibility projections and the state’s RPG. However, as noted in EPA’s RPG guidance “The glidepath is not a presumptive target, and States may establish a RPG that provides for greater, lesser, or equivalent visibility improvement as that described by the glidepath” (EPA, 2007b). Chapter 4 and Appendix D present the 2018 visibility projections for the CENRAP Class I areas and their comparisons with the 2018 URP point using EPA default visibility projection procedures (EPA, 2007a) and EPA default URP glidepaths (EPA, 2003a,b; 2007b).

Various techniques have been developed to display the 2018 visibility modeling results including “DotPlots” that display the 2018 visibility projections as a percentage of meeting the 2018 point on the URP glidepath. A value of 100% on the DotPlot indicates that the Class I area is predicted to meet the 2018 point on the URP glidepath. Over 100% means the 2018 visibility projection obtains more visibility improvements (reductions) than required to meet the 2018 point on the URP glidepath (i.e., projected value is below the glidepath). And less than 100% indicates that fewer visibility improvements are projected than are needed to meet the 2018 point URP on the glidepath (i.e., above the glidepath). Figure 1-4 displays a DotPlot that compares the 2018 visibility projections from the CENRAP 2018 Base G CMAQ simulation with the 2018 URP point using the EPA default RRFs and alternative RRFs that set the CM and Soil RRFs to unity (i.e., assume CM and Soil are natural so remain unchanged from the 2000-2004 Baseline). For these results, the 2018 visibility projections at the Hercules Glade (HEGL1) Class I area meets the 2018 point on the URP glidepath (100%), whereas the 2018 visibility projections at Caney

Creek (CACR), Mingo (MING) and Upper Buffalo (UPBU) achieve more visibility improvements than needed to meet the 2018 URP point so are below the 2018 URP glidepath. However, the 2018 visibility projections at Breton Island comes up slightly short (~5%) of meeting the 2018 point on the URP glidepath and Wichita Mountains (WIMO) comes up approximately 40% short of meeting the 2018 point on the URP glidepath. Class I areas at the northern (e.g., VOYA, BOWA and ISLE) and southern (e.g., BIBE and GUMO) boundaries of the U.S. also fall short of achieving the 2018 URP point. High contributions of international transport and/or natural sources (e.g., wind blown dust) affect the ability of these Class I areas to be on the URP glidepath. These issues are discussed in more detail in Chapters 4 and 5.

Figure 1-4. 2018 visibility projections expressed as a percent of meeting the 2018 URP point for the 2018 BaseG CMAQ base case simulation using the EPA default (EPA, 2007) Regular RRF and alternative projections procedures that set the RRFs for CM=1.0 and CM&SOIL=1.0.

1.3.14 Additional Supporting Analysis

CENRAP performed numerous supporting analyses of its modeling results including analyzing alternative glidepaths and 2018 projection Approaches and performing confirmatory analysis of the 2018 visibility projections. Details on the additional supporting analysis are contained discussed in Chapter 5, which include:

- The CENRAP 2018 visibility projections were compared with those generated by VISTAS and MRPO. There was close agreement between the CENRAP and VISTAS 2018 visibility projections at almost all common Class I areas. With the only exception being Breton Island where the CENRAP's projections were slightly more optimistic than VISTAS'. The MRPO 2018 visibility projections were less optimistic than CENRAP's at the four Arkansas-Missouri Class I area that may have been due to CENRAP's BART emission controls in CENRAP states not included in the 2018 MRPO inventory.
- Extinction based glidepaths were developed and the CENRAP 2018 visibility projections were shown to produce nearly identical estimates of achieving the 2018 URP point when using total extinction glidepaths as when the linear deciview glidepaths were used. With the extinction based glidepaths the analysis of 2018 URP could be made on a PM species-by-species basis where it was shown that 2018 extinctions due to SO₄ and, to a lesser extent, NO₃ and EC, achieve the URP, but the other species do not and in fact extinction due to Soil and CM is projected to get worse.
- 2018 visibility projections were made using EPA's new Modeled Attainment Test Software (MATS) program and the CENRAP Typ02G and Base18G modeling results. The CENRAP 2018 visibility projections exactly agreed with those generated by MATS with three exceptions: Breton Island, Boundary Waters and Mingo Class I areas, At these three Class I areas MATS did not produce any 2018 visibility projections due to insufficient data in the raw IMPROVE database to produce a valid observed 2000-2004 Baseline. CENRAP used filled data for these three Class I areas.
- PM Source Apportionment Technology (PSAT) modeling was conducted to estimate the contributions to visibility impairment at Class I areas by source region (e.g., states) and major source category. Source contributions were obtained for a 2002 and 2018 base case and the PSAT modeling results were implemented in a PSAT Visualization Tool that was provided to CENRAP states and others. Major findings from the PSAT source apportionment modeling include the following:
 - Sulfate from elevated point sources was the highest source category contribution to visibility impairment at CENRAP Class I areas for the worst 20 percent days.
 - International transport contributed significantly to visibility impairment at CENRAP Class I areas on the southern (BIBE and GUMO) and northern (BOWA and VOYA) borders of the U.S. and to a lesser extent at WIMO as well.
- Alternative visibility projections were made assuming that coarse mass (CM) alone and CM and Soil were natural in origin that confirmed the original 2018 visibility projections.
- Visibility projections were made using an alternative model (CAMx) that verified the projections made by CMAQ.
- The effects of International Transport were examined several ways and found that the inability of the 2018 visibility projections to achieve the 2018 URP point at the northern and southern border Class I areas was due to high contributions due to International Transport.

- Visibility trends for the worst 20 percent days, best 20 percent days and all monitored days were analyzed at CENRAP Class I areas using the period of record IMPROVE observations. At most Class I areas there was insufficient years of data to produce a discernable trend. In addition, there was significant year-to-year variability in visibility impairment with episodic events (e.g., wildfires and wind blown dust) confounding the analysis.

1.4 Organization of the Report

Chapter 1 of this TSD presents background, an overview of the approach and summary of the results of the CENRAP meteorological, emissions and air quality modeling. Appendix A contains more details on the meteorological model evaluation discussed in Chapter 1. Details on the emissions modeling are provided in Chapter 2 and Appendix B. The model performance evaluation is given in Chapter 3 and Appendix C. The 2018 visibility projections and comparisons with the 2018 URP point are provided in Chapter 4 with more details given in Appendix D. Chapter 5 contains additional supporting analysis with details on the PM source apportionment modeling and alternative projections provided in Appendices E and F, respectively. Chapter 6 lists the references cited in the report.

2.0 EMISSIONS MODELING

2.1 Emissions Modeling Overview

For the emissions modeling work conducted in support of CENRAP air quality modeling, we used updated 2002 emissions data for the U.S., 1999 emissions data for Mexico, and 2000 emissions data for Canada to generate a final base 2002 Base G Typical (Typ02G) annual emissions database. Numerous iterations of the emissions modeling were conducted using interim databases before arriving at the final Base G emission inventories. The 2002 and 2018 emissions inventories and ancillary modeling data were provided by CENRAP emissions inventory contractors (Pechan and CEP, 2005c,e; Reid et al., 2004a,b; Coe and Reid, 2003), other Regional Planning Organizations (RPOs) and EPA. Building from the CENRAP preliminary 2002 database (Pechan and CEP, 2005e) and 2018 projections (Pechan, 2005d), we integrated several updates to the inventories and ancillary data to create final emissions input files; the final simulations are referred to as 2002 Typical and 2018 Base G, or Typ02G and Base18G. We used the Sparse Matrix Operator Kernel Emissions (SMOKE) version 2.1 processing system (CEP, 2004) to prepare the inventories for input to the air quality modeling systems. The SMOKE simulations documented in this report include emissions generated for annual CMAQ and CAMx simulations at a 36-km model grid resolution, and a short-term CMAQ test simulation at a 12-km model grid resolution. We performed the modeling and quality assurance (QA) work based on the CENRAP modeling Quality Assurance Project Plan (QAPP; Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a).

The Typ02G and Base18G emission inventories represent significant improvements to the preliminary emissions modeling performed by CENRAP (Morris et al., 2005). While the preliminary 2002 modeling served its purpose to develop the infrastructure for modeling large emissions data sets and producing annual emissions simulations, much of the input data (both as inventories and ancillary data) were placeholders for actual 2002 data that were being prepared through calendar year 2005. As these actual 2002 data sets became available, they were integrated into the SMOKE modeling and QA system that was developed during the preliminary modeling, to produce a high-quality emissions data set for use in the final CMAQ and CAMx modeling. The addition of entirely new inventory categories, like marine shipping, added complexity to the modeling. By the end of the emissions data collection phase, there were 23 separate emissions processing streams covering a variety of sources categories necessary to general model-ready emission inputs for the 2002 calendar year.

2.1.1 SMOKE Emissions Modeling System Background

The purpose of SMOKE (or any emissions processor) is to process the raw emissions reported by states and EPA into gridded hourly speciated emissions required by the air quality model. Emission inventories are typically available as an annual total emissions value for each emissions source, or perhaps with an average-day emissions value. The air quality models, however, typically require emissions data on an hourly basis, for each model grid cell (and perhaps model layer), and for each model species. Consequently, emissions processing involves (at a minimum) transformation of emission inventory data by temporal allocation, chemical speciation, spatial allocation, and perhaps layer assignment, to achieve the input requirements of the air quality model. For the CENRAP modeling effort, all of these steps were needed. In

addition, CENRAP processing requires special MOBILE6 processing and growth and control of emissions for the future-year inventories. Finally, the biogenic emission processing using BEIS2 includes additional processing steps. SMOKE formulates emissions modeling in terms of sparse matrix operations. Figure 2-1 shows an example of how the matrix approach organizes the emissions processing steps for anthropogenic emissions, with the final step that creates the model-ready emissions being the merging of all the different processing streams of emissions into a total emissions input file for the air quality model. Figure 2-1 does not include all the potential processing steps, which can be different for each source category in SMOKE, but does include the major processing steps listed in the previous paragraph, except the layer assignment. Specifically, the inventory emissions are arranged as a vector of emissions, with associated vectors that include characteristics about the sources such as its state and county or source classification code (SCC). SMOKE also creates matrices that will apply the gridding, speciation, and temporal factors to the vector of emissions. In many cases, these matrices are independent from one another, and can therefore be generated in parallel. The processing approach ends with the merge step, which combines the inventory emissions vector (now an hourly inventory file) with the control, speciation, and gridding matrices to create model-ready emissions.

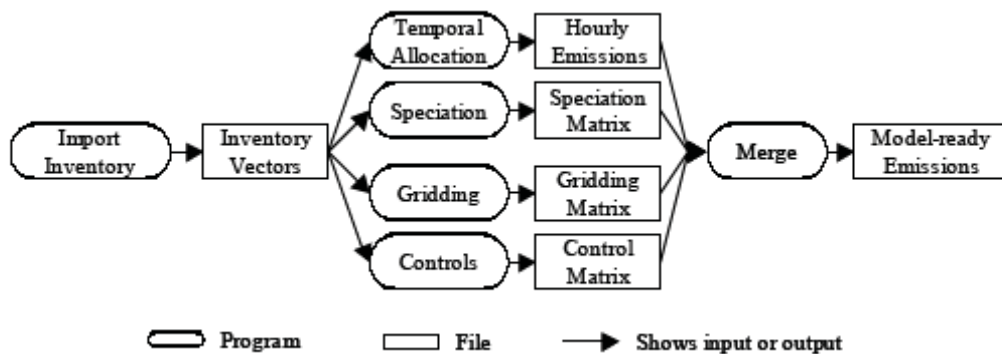

Figure 2-1. Flow diagram of major SMOKE processing steps needed by all source categories.

Temporal processing includes both seasonal or monthly adjustments and day-of-week adjustments. Emissions are known to be quite different for a typical weekday versus a typical Saturday or Sunday. For the day-of-week temporal processing step, emissions may be processed using representative Monday, weekday, Saturday, and Sunday for each month; we refer to this type of processing here as MWSS processing (note that because SMOKE operates in Greenwich Mean Time [GMT] then Monday would include some of local time Sunday so needs to be processed separately from the typical weekday). This approach significantly reduces the number of times the temporal processing step must be run. In the sections below, we have identified the cases in which we have used the MWSS processing approach. Figure 2-2 provides a schematic diagram of SMOKE/BEIS2 processing steps used in this project to generate biogenic emissions rates for Volatile Organic Compounds (VOCs) and oxides of nitrogen (NO_x). Because biogenic emissions are temperature sensitive, they are generated for each day of 2002 using day-specific meteorological conditions from the MM5 meteorological model.

Figure 2-2. Flow diagram of SMOKE/BEIS2 processing steps.

2.1.2 SMOKE Scripts

The scripts are the interface that emissions modelers use to run SMOKE and define the set up and databases used in the emissions modeling so are important for anyone wishing to reproduce the CENRAP SMOKE emissions modeling. Many iterations of the CENRAP SMOKE emissions modeling were performed using updated and corrected emissions data and assumptions resulting in the creation of numerous SMOKE modeling scripts during the course of the study. For the CENRAP annual 2002 SMOKE emissions modeling, the default SMOKE script set up, which is based on source categories, was used to configure the scripts. We made several modifications to the default SMOKE scripts to modularize them, add error checking loops, and break up the report and logs directories by source category. The result is one script for each major source category being modeled that calls all of the SMOKE programs required for simulating that source category. 16 major source categories were modeled by SMOKE for CENRAP. An addition seven SMOKE scripts were also run to set up the emissions modeling. Table 2-1 lists all of the SMOKE scripts used for the 2002 base year modeling and the SMOKE programs called by each script. In addition to the source-specific scripts listed in Table 2-1, we also listed the SMOKE utility scripts that actually call executables, manage the log files, and manage the configuration of the SMOKE simulations.

Table 2-1. Summary of SMOKE scripts.

Source Category	Script Name	SMOKE Programs/Functions
Area	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_ar_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Area fire	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_arf_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Offshore Area	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_ofsar_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Non-road Mobile	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_nr_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Fugitive dust	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_fd_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Road dust	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_rd_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Ammonia*	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_nh3_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
On-road Mobile (non-VMT-based)	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_mb_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
On-road non-US Mobile (non-VMT-based)	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_nusm_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
On-road Mobile (VMT-based)	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_mbv_base02f.csh	smkinev, mbsetup, grdmat, spcmat, premobl, emisfac, temporal, smkmerge, smkreport
WRAP Oil and Gas	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_wog_base02f.csh	smkinev, grdmat, spcmat, temporal, smkmerge, smkreport
Point	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_pt_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Offshore point	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_ofs_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Canadian Point fires	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_bsf_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
All point fires	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_alf_base02f.csh	smkinev, grdmat, spcmat, laypoint, temporal, smkmerge, smkreport
Biogenec	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/sm_k_bg_base02f.csh	Normbies3, tmpbies3, smkmerge
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/make_invidir.csh	builds output file names and directories
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/sm_k_run.csh	Calls SMOKE executables for everything but projection, controls, and QA
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/qa_run.csh	Calls the SMOKE executables for running QA program & names the input/output directories for reports
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/scripts/run/36km/smoke_calls.csh	Calls smk_run.csh, qa_run.csh, configuration and management
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/Assignes/ASSIGNES.cenrap_base02f.cmaq.cb4p25	Sets up the environment variables for use of SMOKE
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/Assignes/sm_k_mkdir	Creates the input/output directories
n/a	/home/aqm2/edss2/cenrap02f/subsys/smoke/Assignes/setmerge_files.scr	Sets up the output environment variables for the smkmerge program

*The nr and nh3 where farther divided to nrm and nry and nh3m and nh3y for the monthly/seasonal and yearly inventories

2.1.3 SMOKE Directory Structures

The SMOKE directories can be divided into three broad categories:

1. Program Directories: These directories contain the model source code, assigns files, scripts and executables needed to run SMOKE.
2. Input Directories: These directories contain the raw emissions inventories, the meteorological data and the ancillary input files.
3. Output Directories: These directories contain all of the output from the model. Also, the output directories contain the MOBILE6 input files.

The directories are described in the Table 2-2. The final pre-merged emission file names and sources of the data re provided in Appendix B.

Table 2-2. Summary of SMOKE directories.

Category	Directory Location	Directory Contents
Program	/home/aqm2/edss2/ cenrap02f/subsys/smoke/src	SMOKE source code
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/assigns	SMOKE assigns files
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/scripts	SMOKE make and run scripts
	/home/aqm2/edss2/ cenrap02f/subsys/smoke/Linux2_x86pg	SMOKE executables
Input	/home/aqm2/edss2/ cenrap02f/data/met	MCIP out metrology files
	/home/aqm2/edss2/ cenrap02f/data/ge_dat	SMOKE ancillary input files
	/home/aqm2/edss2/ cenrap02f/data/inventory/cenrap2002	Raw emissions inventory files
Output	/home/aqm2/edss2/ cenrap02f/data/run_base02f/static	Non-time dependent SMOKE intermediate outputs and MOBILE6 inputs
	/home/aqm2/edss2/ cenrap02f/data/run_base02f/scenario	Time dependent SMOKE intermediate outputs
	/home/aqm2/edss2/ cenrap02f/data/run_base02f/outputs	Model-ready SMOKE outputs
	/home/aqm2/edss2/ cenrap02f/data/reports	SMOKE QA reports

2.1.4 SMOKE Configuration

SMOKE was configured to generate emissions for all months of 2002 on the 36-km unified RPO modeling domain (Figure 1-2). For the anthropogenic emissions sources that use hourly meteorology and daily or hourly data (i.e., on-road mobile sources, point sources with CEM data, point source fires and biogenic sources) we configured SMOKE to represent the daily emissions explicitly. For the non-meteorology dependent emissions, we used a representative Saturday, Sunday, Monday, and weekday for each month as surrogate days for the entire month’s emissions (we refer to this as the MWSS processing approach). For these non-meteorology dependent emissions sources we explicitly represented the holidays as Sundays. Table 2-3 lists the days that we modeled as representative days in the months that we simulated for the 2002 base year modeling. Table 2-4 lists the holidays in 2002 that were modeled as Sundays.

Table 2-3: Representative model days for 2002 base year simulation.

Saturday	Sunday	Monday	Weekday
January 5	January 6	January 7	January 4
February 2	February 3	February 4	February 5
March 2	March 3	March 4	March 5
April 6	April 7	April 8	April 2
May 4	May 5	May 6	May 7
June 8	June 9	June 3	June 4
July 6	July 7	July 8	July 3
August 3	August 4	August 5	August 6
September 7	September 8	September 9	September 10
October 5	October 6	October 7	October 8
November 2	November 3	November 4	November 5
December 7	December 8	December 9	December 10

Table 2-4: 2002 modeled holidays.

Holiday	Date
New Years	January 1, 2002 January 2, 2002
Good Friday	March 29, 2002 March 30, 2002
Memorial Day	May 27, 2002 May 28, 2002
Independence Day	July 4, 2002 July 5, 2002
Labor Day	September 2, 2002 September 3, 2002
Thanksgiving Holiday	November 28-30, 2002
Christmas Holiday	December 24-26, 2002

We used the designations in Table 2-5 to determine which months fell into each season when temporally allocating the seasonal emissions inventories. Some of the inventories for the Electrical Generating Units (EGUs) were received for Winter and Summer. Table 2-6 determines which months fell into each season

Table 2-5. Assignments of months to four seasons for use of seasonal inventory files in SMOKE.

Month	Season

May	Summer
June	Summer
July	Summer
August	Summer
September	Summer
October	Winter
November	Winter
December	Winter

2.1.5 SMOKE Processing Categories

Emissions inventories are typically divided into area, on-road mobile, non-road mobile, point, and biogenic source categories. These divisions arise from differing methods for preparing the inventories, different characteristics and attributes of the categories, and how the emissions are processed through models. Generally, emissions inventories are divided into the following source categories, which we refer to later as “SMOKE processing categories.”

- **Stationary Area Sources:** Sources that are treated as being spread over a spatial extent (usually a county or air district) and that are not movable (as compared to non-road mobile and on-road mobile sources). Because it is not possible to collect the emissions at each point of emission, they are estimated over larger regions. Examples of stationary

area sources are residential heating and architectural coatings. Numerous sources, such as dry cleaning facilities, may be treated either as stationary area sources or as point sources.

- **On-Road Mobile Sources:** Vehicular sources that travel on roadways. These sources can be computed either as being spread over a spatial extent or as being assigned to a line location (called a link). Data in on-road inventories can be either emissions or activity data. Activity data consist of vehicle miles traveled (VMT) and, optionally, vehicle speed. Activity data are used when SMOKE will be computing emission factors via another model, such as MOBILE6 (U.S. EPA, 2005). Examples of on-road mobile sources include light-duty gasoline vehicles and heavy-duty diesel vehicles.
- **Non-Road Mobile Sources:** These sources are engines that do not always travel on roadways. They encompass a wide variety of source types from lawn and garden equipment to locomotives and airplanes. Emission estimates for most non-road sources come from EPA's NONROAD model (OFFROAD in California). The exceptions are emissions for locomotives, airplanes, pleasure craft and commercial marine vessels.
- **Point Sources:** These are sources that are identified by point locations, typically because they are regulated and their locations are available in regulatory reports. In addition, elevated point sources will have their emissions allocated vertically through the model layers, as opposed to being emitted into only the first model layer. Point sources are often further subdivided into electric generating unit (EGU) sources and non-EGU sources, particularly in criteria inventories in which EGUs are a primary source of NO_x and SO₂. Examples of non-EGU point sources include chemical manufacturers and furniture refinishers. Point sources are included in both criteria and toxics inventories.
- **Biogenic Land Use Data:** Biogenic land use data characterize the types of vegetation that exist in either county-total or grid cell values. The biogenic land use data in North America are available using two different sets of land use categories: the Biogenic Emissions Landcover Database (BELD) version 2 (BELD2), and the BELD version 3 (BELD3) (CEP, 2004b).

In addition to these standard SMOKE processing categories, we have added other categories either to represent specific emissions processes more accurately or to integrate emissions data that are not compatible with SMOKE. Examples of emissions sectors that fall outside of the SMOKE processing categories include emissions generated from process-based models for representing windblown dust and agricultural ammonia (NH₃) sources. An emissions category with data that are not compatible with SMOKE is one with gridded emissions data sets, such as commercial marine sources. Another nonstandard emissions category that we modeled was emissions from fires. All of the emissions categories that we used to build CENRAP simulations are described in detail in the following sections.

Continuing the enhancement of the emissions source categories that we initiated during the preliminary 2002 modeling, we further refined the categories from the standard definitions listed above to include more explicit emissions sectors. The advantage of using more detailed definitions of the source categories is that it leads to more flexibility in designing control strategies, substituting new inventory or profile data into the modeling, managing the input and output data from SMOKE and conducting QA of the SMOKE outputs. The major drawback to defining more emissions source categories is the increased level of complexity and computational requirements (run times and disk space) that results from having a larger number of input data sets. Another motivation behind separating the various emissions categories is related to the size and flexibility of the input data. Some data sets, like the CENRAP on-road

mobile inventory, were so large that we had to process them separately from the rest of the sources in the on-road sector due to computational constraints. We also separated the non-road mobile and ammonia sectors into yearly and monthly inventories to facilitate the application of uniform monthly temporal profiles to the monthly data. Additional details about how we prepared the emissions inventories and ancillary data for modeling are described in Sections 2.2 through 2.16. Table 2-7 summarizes the entire group of source sectors that composed simulation Typ02G. Each emissions sector listed in the table represents an explicit SMOKE simulation. As discussed in Section 2.1.2 below, after finishing all of the source-specific simulations, we used SMOKE to combine all of the data into a single file for each day for input to the air quality modeling systems. Each subsection on the emissions sectors describes each sector in terms of the SMOKE processing category, the year covered by the inventory, and the source(s) of the data.

Additional details about the inventories are also provided, including any modifications that we made to prepare them for input into SMOKE.

Table 2-7. CENRAP Typ02G emissions categories.

Emissions Sector	Abbreviation*
Fires as Point Sources (WRAP, CENRAP, VISTAS)	Alf
Area Sources (All domain)	ar
CENRAP area fires	arf
Area fires, Anthropogenic (All domain, excluding WRAP and CENRAP)	arfa
Area fires, Wild (All domain, excluding WRAP)	arfw
Biogenic	b3
Ontario, Canada, point-source fires	bsf
Fugitive dust	fd
WRAP on-road mobile	mb
CENRAP on-road mobile	mbv_CENRAP
Other US on-road mobile	mbv
Monthly CENRAP/MRPO anthropogenic NH ₃	nh3m
Ammonia from annual inventory (CENRAP)	nh3y
WRAP anthropogenic NH ₃	nh3
Seasonal/Monthly non-road mobile (WRAP, CENRAP, MW)	nrm
Annual non-road mobile	nry
On-road Mobile (Non-US)	nusm
Offshore shipping (Gulf, Atlantic)	ofs
Offshore area (Gulf)	ofsar
Stationary point (All domain, including offshore)	pt
Road dust	rd
Windblown dust (All domain)	wb_dust
WRAP oil and gas	wog

*These abbreviations are used in the file naming of the SMOKE output files for each sector.

Emissions models such as SMOKE are computer programs that convert annual or daily estimates of emissions at the state or county level to hourly emissions fluxes on a uniform spatial grid that are formatted for input to an air quality model. For the Typ02G and Base18G emission inventories we prepared emissions for CMAQ version 4.5 using SMOKE version 2.1 on the UCR Linux computing cluster. SMOKE integrates annual county-level emissions inventories with source-based temporal, spatial, and chemical allocation profiles to create hourly emissions fluxes on a predefined model grid. For elevated sources that require allocation of the emissions to the vertical model layers, SMOKE integrates meteorology data to derive dynamic vertical profiles. In addition to its capacity to represent the standard emissions processing categories, SMOKE is also instrumented with the Biogenic Emissions Inventory System, version 3 (BEIS3) model for estimating biogenic emissions fluxes (U.S. EPA, 2004) and the MOBILE6 model for estimating on-road mobile emissions fluxes from county-level vehicle activity data (U.S. EPA, 2005a).

SMOKE uses C-Shell scripts as user interfaces to set configuration options and call executables. SMOKE is designed with flexible QA capabilities to generate standard and custom reports for checking the emissions modeling process. After modeling all of the source categories individually, including those categories generated outside of SMOKE, we used SMOKE to merge all of the categories together to create a single CMAQ input file per simulation day. Also, for use in the CAMx modeling, we converted the CMAQ-ready emissions estimates to CAMx-ready files using the CMAQ2CAMx converter. Additional technical details about the version of SMOKE used for final simulations are available from CEP (2004b). All scripts, data, and executables used to generate the Typ02G and Base18G emissions for CMAQ and CAMx are archived on the CENRAP computing cluster.

2.1.6 2002 and 2018 Data Sources

This section describes the procedures that the CENRAP followed to collect and prepare all emissions data for Typ02G and Base18G simulations. We discuss the sources of all inventory and ancillary data used for simulations. CENRAP worked with emissions inventory contractors, other RPOs, and EPA to collect all of the data that constitute the simulation. Table 2-8 lists all of the contacts for the various U.S. anthropogenic emission inventories we used. For the CENRAP inventories, this table lists the contacts for the contractors who prepared the inventories; for the non-CENRAP inventories it lists the contacts at the RPOs who provided us inventory data. We obtained the emissions inventories for Canada and Mexico from the U.S. EPA Emissions Factors and Inventory Group (EFIG) via the Clearinghouse for Inventories and Emissions Factors (CHIEF) website (<http://www.epa.gov/ttn/chief/index.html>).

As mentioned above, the refinement of these inventories involved splitting some of the inventory files into more specific source sectors. As the stationary-area-source emissions sector has traditionally been a catch-all for many types of sources, this is the inventory sector that required the greatest amount of preparation. Upon receiving all stationary-area-source inventories we extracted fugitive dust, road dust, anthropogenic NH₃, and for the non-WRAP U.S. inventories, stage II refueling sources. We retained the dust sources as separate categories that we would further refine with the application of transport factors (see Section 2.8).

We collected the ancillary data used for SMOKE modeling from several sources. SMOKE ancillary modeling data include:

- Temporal and chemical allocation factors by state, county, and source classification code (SCC);
- Spatial surrogates and cross-reference files for allocating county-level emissions to the model grid;
- Hourly gridded meteorology data;
- Stack defaults for elevated point sources;
- MOBILE6 configuration files;
- A Federal Implementation Standards (FIPS) codes (i.e., country/state/county codes) definition file;

September 2007

- A Source Category Classification (SCC) codes definition file;
- A pollutant definition file; and
- Biogenic emission factors.

Except for the meteorology data and the MOBILE6 configuration files, we used default data sets provided by EPA as the basis for all of the ancillary data except for temporal profiles used for Electric Generating Units (EGUs). These profiles were developed based on CEM data from 2000 through 2003 (Pechan and CEP, 2005c). CENRAP provided the meteorology data for the simulations at 36-km and 12-km grid resolutions (Johnson, 2007). The inventory contractor who prepared the MOBILE6 inventories provided the MOBILE6 configuration files either directly or via an RPO representative; details about the sources of the MOBILE6 inputs are provided in Section 2.4. We made minor modifications to the chemical allocation, pollutant definition, and country/state/county codes files for new sources, pollutants, or counties contained in the inventories that we had not previously modeled. We made major modifications to the temporal and spatial allocation inputs, as described below.

2.1.7 Temporal Allocation

Temporally allocating annual, daily, or hourly emissions inventories in SMOKE involves combining a temporal cross-reference file and a temporal profiles file.

- Temporal cross-reference files associate monthly, weekly, and diurnal temporal profile codes with specific inventory sources, through a combination of a FIPS (country/state/county) code, an SCC, and sometimes for point sources, facility and unit identification codes.
- Temporal profiles files contain coded monthly, weekly, and diurnal profiles in terms of a percentage of emissions allocated to each temporal unit (e.g., percentage of emissions per month, weekday, or hour).

As a starting point for the temporal allocation data for simulations, we used the files generated by emission inventory contractors (Pechan and CEP, 2005c). Based on guidance from the developers of some of the inventory files, we enhanced the temporal profiles and assignments for some source categories (Pechan, 2005b).

We modified the temporal allocation data for the simulations to improve the representation of temporal emissions patterns for certain source categories. We implemented the adjusted profiles in SMOKE by modifying the temporal cross-reference file for the applicable FIPS and SCC combinations.

Updated temporal profiles for EGUs were made available for MRPO in the MRPO Base K inventory. Since the non-road emissions for IA and MN were monthly emissions developed by MRPO, new temporal profiles were created for all the SCCs in these emissions files for these two states only. The monthly profile was uniform and the weekly and diurnal profiles were kept the same as were modeled for the rest of the country.

An updated temporal profile, profile 485, based on NOAA 1971-2000 population weighted average heating degree days for home heating area source emissions was obtained from

September 2007

VISTAS. This profile provided state specific updates for home heating emissions and was applied to the full inventory in place of profile 17XX.

Other additions to the Base02G temporal allocation data included updates that made by other RPOs that are applicable to their inventories. These other updates to the temporal allocation files included

- VISTAS continuous emissions monitoring (CEM)-specific profiles for EGUs in the VISTAS states;
- VISTAS agricultural burning profiles;
- Wildfire and prescribed fire profiles developed by VISTAS for the entire U.S.;
- MANE-VU on-road mobile profiles;
- WRAP weekly and diurnal road dust profiles;
- WRAP diurnal wildfire, agricultural fire, and prescribed fire profiles; and
- WRAP on-road mobile weekly and diurnal profiles.

Finally, for all of the monthly and seasonal emissions inventories, we modified the temporal cross-reference files to apply uniform monthly profiles to the sources contained in these inventories. The monthly variability is inherent in monthly and seasonal inventories and does not need to be reapplied through the temporal allocation process in SMOKE. The inventories to which we applied uniform monthly temporal profiles included:

- WRAP, CENRAP, and MRPO non-road mobile sources;
- WRAP on-road mobile sources;
- WRAP road dust; and
- CENRAP anthropogenic ammonia.

2.1.8 Spatial Allocation

SMOKE uses spatial surrogates and SCC cross-reference files to allocate county-level emissions inventories to model grid cells. Geographic information system (GIS)-calculated fractional land use values define the percentage of a grid cell that is covered by standard sets of land use categories. For example, spatial surrogates can define a grid cell as being 50% urban, 10% forest, and 40% agricultural. In addition to land use categories, spatial surrogates can also be defined by demographic or industrial units, such as population or commercial area. Similar to the temporal allocation data, an accompanying spatial cross-reference file associates the spatial surrogates (indexed with a numeric code) to SCCs. Spatial allocation with surrogates is applicable only to area and mobile sources that are provided on a county level basis. Point sources are located in the model grid cells by SMOKE based on the latitude-longitude coordinates of each source. Biogenic emissions are estimated based on 1-km² gridded land use information that is mapped to the model grid using a processing program such as the Multimedia Integrated Modeling System (MIMS) Spatial Allocator (CEP, 2004).

We used various sources of spatial surrogate information for the U.S., Canada, and Mexico inventories in the simulations. For the U.S. and Canadian sources, we used the EPA unified

surrogates available through the EFIG web site (EPA, 2005c). For the 36-km grid, EPA provides these data already formatted for SMOKE on the RPO Unified 36-km domain that we used for the simulations. We modified the spatial surrogates for Canada on the RPO Unified 36-km domain by adopting several surrogate categories that were enhanced by the WRAP. Table 2-9 provides details about the new Canadian spatial surrogates that were developed by the WRAP and used for CENRAP simulations. For modeling Mexico, we used Shapefiles developed for the Big Bend Regional Aerosol and Visibility Observations Study (BRAVO) modeling to create surrogates for Mexico on the RPO Unified 36-km domain (EPA, 2005c).

Table 2-9. New Canadian spatial surrogates.

Attribute	Base02a Code	Shapefile	Reference
Land area	950	can_land93_land	Natural Resources Canada (1993) AVHRR land cover data
Water area	951	can_land93_water	Natural Resources Canada (1993) AVHRR land cover data
Forest land area	952	can_land93_forest	Natural Resources Canada (1993) AVHRR land cover data
Agricultural land area	953	can_land93_agri	Natural Resources Canada (1993) AVHRR land cover data
Urban land area	954	can_land93_urban	Natural Resources Canada (1993) AVHRR land cover data
Rural land area	955	can_land93_rural	Natural Resources Canada (1993) AVHRR land cover data
Airports	956	can_airport	U.S. DOT Bureau of Transportation Statistics (2005) NORTAD 1:1,000,000 scale data
Ports	957	can_port	U.S. DOT Bureau of Transportation Statistics (2005) NORTAD 1:1,000,000 scale data
Roads	958	can_road1m	Natural Resources Canada (2001) National Scale Frameworks data
Rail	959	can_rail1m	Natural Resources Canada (1999) National Scale Frameworks data

2.2 Stationary Point Source Emissions

Stationary-point-source emissions data for SMOKE consist of (1) Inventory Data Analyzer (IDA)-formatted inventory files; (2) ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx; and (3) meteorology data for calculating plume rise from the elevated point sources. This section describes where CENRAP obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.2.1 Data Sources

For the stationary-point-source inventories in Typ02G and Base18G, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the BRAVO 1999 Mexican inventory. The BRAVO inventory was updated with entirely new inventories for the six northern states of Mexico for stationary area, as well as stationary point, on-road mobile, and off-road mobile sources. Emissions for the southern states of Mexico were included for the first time in CENRAP simulations Typ02G and Base18G. These data were provided by ERG, Inc., who completed an updated 1999 emissions inventory for northern Mexico (ERG, 2006b) and delivered these data to the WRAP. The CENRAP stationary-point inventory consisted of annual county-level and tribal data provided in August of 2005 (Pechan and CEP, 2005e). The WRAP (ERG, 2006a) and VISTAS Base G (MACTEC, 2006) stationary-point inventories consisted of an annual data set and monthly CEM data for selected EGUs. The WRAP and VISTAS provided these data directly to CENRAP. We downloaded the MANE-VU stationary-point inventories from the MANE-VU web sites. MRPO base K data was downloaded and processed for SMOKE modeling by Alpine Geophysics under contract from MARAMA. UCR entered into a nondisclosure agreement with Environment Canada to obtain version 2 of the 2000 Canadian point-source inventory. This inventory represented a major improvement over the version of the data that we had used in the preliminary 2002 modeling.

Reductions anticipated from BART controls for electric generating units (EGU) in Oklahoma, Arkansas, Kansas, and Nebraska were included in projections of 2018 emissions. These anticipated reductions were based on actual operating conditions and estimated control efficiencies from utilities.

Newly permitted coal-fired utilities were included in 2018 projections. Conservatively, no IPM projected new units were removed from the simulation with the addition of the permitted facilities.

Due to missing or clearly erroneous stack parameters, several facilities in CENRAP states were relegated to default stack profiles based on SCC in the NEI QA process. Prioritizing for the largest emissions sources, these default parameters were corrected by CENRAP States and updated files were provided to modeling contractors. Final IDA input files Typ02G and Base18G for point sources reflect State corrections.

For coal-fired point and area sources, The EPA Office of Air Quality and Planning Standards (OAQPS) determined that the organic carbon fraction in the speciation profile code "NCOAL" was not representative of most coal combustion occurring in the U.S. This profile has an organic carbon fraction of 20%, which includes an adjustment factor of 1.2 to account for other atoms (like oxygen) attached to the carbon. OAQPS has reverted back to the profile code "22001" for coal combustion, which has an organic carbon fraction of 1.07% (again including the 1.2 factor adjustment). This is the same profile that EPA used for previous rulemaking efforts including the Heavy Duty Diesel Rule and Non-Road Rule, which were proposed (and publicly reviewed) prior to the introduction of the NCOAL profile.

The consensus in OAQPS is that the NCOAL profile has a high organic carbon percentage because it is based on measurements of combustion of lignite coal. With the exception of Texas, lignite is not widely used in the U.S.. Thus, OAQPS staff stopped relying on this profile as a national default profile. A new coal speciation profile developed based on Eastern bituminous

coal combustion (since much of the coal burned in the U.S. is of this type) is being developed by EPA's Office of Research and Development but was not completed for this study.

The profile recently developed for MRPO by Carnegie Mellon was provided to CENRAP and is representative of combustion of eastern bituminous coal. This profile is a more appropriate profile for most facilities in the U.S. than the default NCOAL profile.

Additionally, the "22001" profile has been flagged as problematic because of the apparent inadvertent switching of the organic carbon and elemental carbon fractions, which are 1.07% and 1.83% respectively. The report discovering the discrepancy in the profile did not offer a clear alternative to correct the problem (MACTEC, 2003).

CENRAP has continued to use the NCOAL factor for facilities burning lignite in North Dakota and Texas. For the remainder of the U.S., the MRPO profile, CMU, was used. The NCOAL factor was modified reducing the organic carbon by half and assigning the remainder to PM_{2.5}. The modification was at the request of Texas and was reflective of the original study for the NCOAL factor conducted in Texas (Chow, 2005). Table 2-10 summarizes the PM_{2.5} speciation profiles for the NCOAL, 2201 and CMU speciation profiles for coal burning sources.

Table 2-10. PM 2.5 speciation profiles for coal-burning sources.

Profile	POC	PEC	PNO3	PSO4	PM2.5
NCOAL	0.1000	0.0100	0.0050	0.1600	0.7250
22001	0.0107	0.0183	0.0000	0.1190	0.8520
CMU	0.0263	0.0315	0.0036	0.0447	0.8938

Final simulations used improved temporal allocation and speciation information relative to the preliminary 2002 modeling; the rest of the ancillary data for modeling stationary point sources stayed the same (Mansell et al., 2005).

2.2.2 Emissions Processing

For Typ02G and Base18G simulations we configured SMOKE to process the annual inventories for the U.S., Canada, and Mexico and process hourly CEM data for the VISTAS. We configured SMOKE to allocate these emissions up to model layer 15 (approximately 2,500 m AGL), which roughly corresponds to the maximum planetary boundary layer (PBL) heights across the entire domain throughout the year. As coarse particulate matter (PMC) is not an inventory pollutant but is required by the air quality models as input species, we used SMOKE to calculate PMC during the processing as (PM₁₀ - PM_{2.5}). With the SMOKE option WKDAY_NORMALIZE set to "No," we treated the annual inventories based on the assumption that they represent average-day data based on a seven-day week, rather than average weekday data. We also assumed that all of the volatile organic compound (VOC) emissions in the inventories are reactive organic gas (ROG), and thus used SMOKE to convert the VOC to total organic gas (TOG) before converting the emissions into CB-IV speciation for the air quality models. To capture the differences in diurnal patterns that are contained in the CEM temporal profiles for VISTAS and CENRAP states (Base02F), we configured SMOKE to generate daily temporal matrices, as opposed to using a Monday-weekday-Saturday-Sunday (MWSS) temporal allocation approach.

September 2007

To QA the stationary-point emissions, we used the procedures in the CENRAP emissions modeling QA protocol (Morris and Tonnesen, 2004) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for all simulations. These QA graphics are available on the web site at: <http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml>

2.2.3 Uncertainties and Recommendations

There were issues with the stationary-point emissions that we left unresolved at the completion of the Typ02G and Base18G emissions modeling either because we did not feel they would have a major impact on the modeling results in CENRAP states or because we did not have alternative approaches and they represented the best available information. Canadian emissions for 2000 were found to have a significant number of missing stack parameters. These stacks when modeled with default parameters frequently resulted in lower plume heights. Stack parameters for 2000 were corrected based on cross referencing sources with the 2005 Canadian inventory for the largest emitting points. Stack parameters for many of the sources with lower emissions remain incorrect, but are assumed to have a less significant impact on CENRAP Class I areas. The 2020 projected emissions for Canada were obtained as air quality model-ready files from EPA. EPA has not confirmed that missing stack parameters were corrected for the projected inventory. It is assumed that they were not corrected and default parameters were used instead. Given confidentiality issues that surround Canadian inventories, EPA processed emissions represent the best available data.

2.3 Stationary Area Sources

Stationary-area-source emissions data for SMOKE consist of IDA-formatted inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.3.1 Data Sources

For the stationary area source inventories in the Typ02G and Base18G simulations, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the updated Mexican inventory, <http://www.epa.gov/ttn/chief/net/mexico.html>. The BRAVO inventory was updated with entirely new inventories for the six northern states of Mexico for stationary area, as well as stationary point, on-road mobile, and off-road mobile sources. Emissions for the southern states of Mexico were included for the first time in CENRAP simulations Typ02G and Base18G. The CENRAP stationary-area inventory consisted of annual county-level and tribal data provided by in August of 2005 (Pechan and CEP, 2005e). The WRAP (ERG, 2006a) and VISTAS Base G (MACTEC, 2006) stationary-area inventories consisted of an annual data set. We downloaded the MANE-VU stationary-area inventories from the MANE-VU web sites. MRPO base K data was downloaded and processed for SMOKE modeling by Alpine Geophysics under contract from MARAMA.

To prepare the stationary-area inventories for modeling, we made several modifications to the files by removing selected sources either to model them as separate source categories or to omit them from simulations completely. Using guidance provided by EPA (EPA, 2004b), we extracted fugitive and road dust sources from all stationary-area inventories for adjustment by transport factors and modeling as separate source categories (see Section 2.8). We also extracted and discarded the stage II refueling sources (Table 2-11) from the U.S. inventories; we modeled these sources with MOBILE6 as part of the on-road mobile-source emissions. We left the stage II refueling emissions in the WRAP stationary-area inventory because the on-road mobile inventory that we received for this region did not contain these emissions.

Table 2-11. Refueling SCCs removed from the non-WRAP U.S. stationary-area inventory.

SCC	Description
2501060100	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Total
2501060101	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Displacement Loss/Uncontrolled
2501060102	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Displacement Loss/Controlled
2501060103	Storage and Transport Petroleum and Petroleum Product Storage Gasoline Service Stations Stage 2: Spillage
2501070100	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Total
2501070101	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Displacement Loss/Uncontrolled
2501070102	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Displacement Loss/Controlled
2501070103	Storage and Transport Petroleum and Petroleum Product Storage Diesel Service Stations Stage 2: Spillage

Other steps that we took to prepare the stationary-area inventories included confirming that there is no overlap between the anthropogenic NH₃ inventory (Section 2.9) and stationary area sources, and moving area-source fires in each regional inventory to separate files. In addition to these inventory modifications we made a few changes to the ancillary data files for simulation Typ02G, as described next.

Simulation Typ02G used improved temporal and spatial allocation information relative to the preliminary 2002 modeling; the rest of the ancillary data for modeling stationary area sources stayed the same as in the preliminary 2002 modeling (Mansell et al., 2005). We adopted enhanced spatial allocation data with additional area-based surrogates for Canada (Table 2-9), and added surrogates for a missing county in Colorado (Broomfield) from WRAP modeling and QA work. The WRAP had noticed when looking at the Canadian data for the preliminary 2002 modeling that forest fire emissions from the Canadian area-source inventory, which are relatively large sources of CO, NO_x, and PM_{2.5}, were being allocated to a surrogate for logging activities. They found similar discrepancies for other area and non-road SCCs in Canada. To improve the representation of the Canadian emissions, we adopted several land-area-based surrogates developed by the WRAP, such as forested land area, urban land area, and rural land area, and made the accompanying additions to the spatial cross-reference file to associate inventory SCCs with these surrogates. We also added spatial surrogates for Broomfield County, CO; this county was included in the inventory but was not included in the base EPA surrogates (this county was recently created from portions of other counties).

Improvements to the temporal allocation data for simulation Typ02G included the addition of several FIPS-specific profiles provided by VISTAS and CENRAP contractors (Pechan 2005b). These temporal profiles listed in Table 2-12 targeted mainly fire and agricultural NH₃ sources, such as open burning and livestock operations, respectively.

Table 2-12. New Temporal Profile Assignments for CENRAP Area Source SCCs.

2.3.2 Emissions Processing

For simulations Typ02G and Base18G we configured SMOKE to process the annual stationary-area-source inventories for the U.S., Canada, and Mexico. As PMC is not an inventory pollutant but is required by the air quality models as input species, we used SMOKE to calculate PMC during the processing as (PM₁₀ - PM_{2.5}). With the SMOKE option WKDAY_NORMALIZE set to “Yes,” we treated the annual stationary-area inventories based on the assumption that they represent average weekday data, causing SMOKE to renormalize the data to a seven-day estimate before applying any temporal adjustments. We also assumed that all of the VOC emissions in the inventories are ROG and thus used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to use a MWSS temporal allocation approach, as opposed to a daily temporal approach.

To QA the stationary-area emissions, we used the procedures in the CENRAP modeling QAPP and Modeling Protocol (Morris and Tonnesen, 2004; Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for all simulations. The graphical QA summaries include, for all emissions output species, daily spatial plots summed across all model layers, daily time-series plots, and annual time-series plots. These QA graphics are available on the UCR/CENRAP web site at <http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml>.

2.3.3 Uncertainties and Recommendations

Most of the issues that we encountered with the stationary area sources related to the removal of certain SCCs from the base inventories for inclusion as other source categories or complete omission from simulations. We spent considerable effort on ensuring that we did not have overlap between the area inventory and the other sectors that explicitly represent sources traditionally contained in the area inventory, such as NH₃ and dust.

Both the Canadian and Mexican inventories presented minor problems that we resolved for simulation Typ02G but that can be addressed more thoroughly in future simulations. The Canadian inventory we used contained data only at the province level, essentially equivalent to a statewide rather than county-level inventory. A higher resolution inventory would have allowed us to use higher-resolution and more accurate spatial allocation data. Future modeling that uses Canadian data should move to the newly released municipality-level year 2000 inventories for Canada.

There was a discrepancy between the state and county coding in the Mexican inventory and the SMOKE file that defines acceptable FIPS codes. Differences in the ordering of the Mexican state names between these two data sets led to some of the Mexican inventory sources being mislabeled in the SMOKE QA reports. The state codes in the inventory and spatial surrogate files for two Mexican states were changed to be consistent with the SMOKE country/state/county codes file.

2.4 On-Road Mobile Sources

On-road mobile-source emissions data for SMOKE consist of IDA-formatted emissions and vehicle activity inventory files, and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.4.1 Data Sources

The SMOKE processing for CENRAP included two approaches for processing on-road mobile sources depending on the source of the data provided. The first approach was to compute mobile emissions values prior to providing them to SMOKE; we call this the pre-computed emissions approach. The second approach was to provide SMOKE with VMT data, meteorology data, and MOBILE6 inputs, and let the SMOKE/MOBILE6 module compute the mobile emissions based on these data; we call this the VMT approach. These approaches are not mutually exclusive for a single SMOKE run; therefore, we performed single SMOKE runs in which both approaches were used as follows:

- Annual VMT for computing CO, NO_x, VOC, SO₂, NH₃ and PM using MOBILE6 for all CENRAP States.
- Pre-computed, seasonal MOBILE6-based emissions of all pollutants for the 13 WRAP states that included pre-specified PM_{2.5} data.
- Annual VMT for computing CO, NO_x, VOC, SO₂, NH₃ and PM using MOBILE6 for the rest of the United States (VISTAS, MRPO and MANE-VU).
- Pre-computed, annual 1999 emissions of all pollutants for Mexico.
- Pre-computed, annual 2000 emissions of all pollutants for Canada.

For the CENRAP states, STI provided VMT data and MOBILE6 input files for all counties in the CENRAP region (Reid et al., 2004a). MOBILE6 input files were provided only for the months of January and July for 2002. MOBILE6 input files for the remaining months of 2002 had to be generated. These data were then processed within SMOKE. Using one set of MOBILE6 input files for each county in the CENRAP states resulted in compute memory requirements that were too large to process all CENRAP states together. Therefore the on-road mobile processing for the CENRAP states was split into two groups for SMOKE processing. The resulting gridded emissions data files were then merged together to obtain an on-road mobile source emissions file for the entire CENRAP region.

For the WRAP states we used actual 2002 data split into California and non-California seasonal inventories that were provided by the WRAP (Pollack et al., 2006). In addition to the standard criteria pollutants, these files contained pre-specified PM_{2.5} emissions. For the rest of the U.S. we used annual county-level activity and speed inventories with monthly, county-level MOBILE6 inputs, and hourly meteorology to estimate the hourly emissions with the SMOKE/MOBILE6 module. For the non-U.S. inventories, we used version 2 of the year 2000 Canadian inventory and the updated 1999 Mexican inventory pre-computed mobile source emissions.

2.4.2 Emissions Processing

For the Typ02G emissions modeling we configured SMOKE to process the annual on-road mobile emissions inventory data for the WRAP, Canada, and Mexico as pre-computed inventories. For the non-WRAP states, we used the SMOKE/MOBILE6 integration to process the annual activity inventories and monthly, county-based roadway information. The WRAP inventories contained pre-computed speciated PM emissions (Pollack et al, 2006) so the SMOKE PM speciation module was not used. The WRAP on-road mobile inventories were developed to represent seven-day (weekly) average emissions (as compared to the area source inventory, which represented average weekday emissions). As actual weekly average emissions, we configured SMOKE to process the WRAP on-road mobile source emissions by setting WKDAY_NORMALIZE to “No” in which case the emissions are adjusted to represent weekday and Saturday and Sunday emissions (as in contrast to the area sources where the emissions are just adjusted for Saturday and Sunday). We also assumed that all of the VOC emissions in the inventories are ROG and used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to create day-of-week specific rather than MWSS, temporal profiles because the WRAP on-road mobile temporal profiles contain weekly profiles that vary across the weekdays.

As noted previously, the large number of county roadway inputs for MOBILE6 processed for the non-WRAP portion of the U.S. required us to split the states mobile-source processing into three subsets because of computer memory limitations. Separate MOBILE6 input files were used for each separate county for CENRAP states, where as one MOBILE6 input file was used for several counties outside of the CENRAP region. The three subsets consisted of two sets of SMOKE/MOBILE6 simulations for the CENRAP and a simulation that computed on-road mobile emissions for the MRPO, VISTAS, and MANE-VU states. We configured MOBILE6 to use weekly temperature averaging for computing these emissions within SMOKE.

To QA the on-road mobile emissions, we used the CENRAP emissions modeling QA protocol (Morris and Tonnesen, 2004; Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations Typ02G and Base18G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#mb

2.4.3 Uncertainties and Recommendations

We approached the on-road mobile emissions preparation for simulation Typ02G from three different directions, which were based on the form of the input inventories and ancillary emissions data for different regions of the modeling domain:

- The WRAP region used emissions estimates pre-computed with EMFAC for California and MOBILE6 for the rest of WRAP states and processed like area sources with SMOKE adjusted from weekly to day-of-week emissions.
- The CENRAP, VISTAS, MRPO, and MANE-VU states used county-level activity data to compute emissions with the SMOKE/MOBILE6 module.

- The non-U.S. parts of the domain also had pre-computer on-road mobile source emissions so used an area-source approach for processing with SMOKE.

Different approaches for modeling a single emissions sector adds complexity and additional sources of error and inconsistencies to the modeling because of the different assumptions that went into the preparation of the input data. For example, refueling emissions from the on-road mobile sector are represented in the WRAP area-source sector but are computed with MOBILE6 for the rest of the U.S. Not using MOBILE6-based emissions for the non-U.S. portion of the domain neglects the effects of the actual 2002 meteorology on these emissions. Applying MOBILE6 outside of the U.S. is currently not possible because MOBILE6 is instrumented only for calculating emissions for the U.S. automotive fleet. The result of using MOBILE6 to calculate U.S. emissions and not using it to calculate the non-U.S. on-road mobile emissions estimates is that the non-U.S. emissions are not specific to this modeling year and the 2002 meteorological conditions, whereas the U.S. emissions are 2002-specific.

While we used the best available information to compute the on-road mobile emissions for the various portions of the modeling domain, inconsistent approaches for representing these emissions may lead to unnatural emissions gradients along political boundaries. We recommend for future work a unified approach for at least the U.S. inventories, where either we use MOBILE6 in SMOKE for the entire domain (or alternative emissions model such as CONCEPT), or we calculate the emissions with MOBILE6 outside of SMOKE and then use the resulting county-based emissions inventories.

2.5 Non-Road Mobile Sources

Non-road mobile source emissions data for SMOKE consist of annual, seasonal, and monthly IDA-formatted emission inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA that we performed to ensure that SMOKE processed the data as expected.

2.5.1 Data Sources

The non-road mobile-source inventories in the Typ02G and Base18G emissions modeling used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory and the improved 1999 Mexican inventory. The U.S. inventories consisted of annual, seasonal, and monthly inventories; the non-U.S. inventories were annual data. Pechan provided the CENRAP inventories divided between annual data for aircraft, locomotive, and commercial marine and annual files for all other non-road sources (Pechan and CEP, 2005e). Minnesota substituted the monthly MRPO Base K non-road inventory for the CENRAP inventory in their state. Iowa substituted the monthly estimates for non-road agricultural sources from the MRPO base K inventory for the CENRAP inventory. Texas provided estimates for 2002 non-road emissions in lieu of the CENRAP prepared inventory. WRAP provided non-road inventories divided between California and non-California seasonal inventories, further subdivided into aircraft, locomotives, shipping, and all other non-road mobile sources (Pollack et al., 2006). Note that the California Air Resources Board uses their own OFFROAD model for California non-

road emissions, whereas the EPA NONROAD model is used for the rest of the states (with the exception of locomotives, aircraft and shipping). With these data WRAP also provided temporal adjustments to apply to the inventories to split them between weekday and weekend emissions. We used these weekday/weekend splits to derive new weekly temporal profiles for the WRAP sources. The MRPO base K monthly non-road inventories were obtained from MRPO in NIF format and were converted to SMOKE format by Wendy Vit of the Missouri DNR. The VISTAS Base G and MANE-VU non-road mobile inventories consisted of annual county-level data (Pechan and CEP, 2005c). We received these inventories directly from the respective RPO inventory representatives. We received the Canadian 2000 inventory version 2 from the U.S. EPA EFIG (EPA, 2005d). For Mexico we used the improved 1999 inventory available at <http://www.epa.gov/ttn/chief/net/mexico.html>.

Along with adding the WRAP weekday/weekend emissions splits to the temporal allocation files, we also created temporal input files that apply a flat, uniform monthly profile to the monthly and seasonal non-road inventories. With the monthly and seasonal variability inherent in these inventories, we avoided applying redundant monthly profiles by splitting the inventories into seasonal/monthly and annual data. We applied the uniform monthly temporal profiles to the seasonal/monthly inventories and non-uniform monthly temporal profiles to the annual inventories. How the non-road emissions inventory data were split into those with monthly/seasonal emission and those with annual emissions is provided in Table 2-13.

Table 2-13. Non-road mobile-source inventory temporal configuration.

Region	Source	Temporal Coverage
WRAP (non-CA)	Non-road mobile	Seasonal
WRAP (CA)	Non-road mobile	Seasonal
WRAP	Aircraft	Seasonal
WRAP	Locomotive	Annual
WRAP	In-port and near-shore shipping	Annual
CENRAP	All non-road	Annual
CENRAP, IA	Non road Ag.	Monthly
VISTAS	All non-road	Annual
MRPO and MN	All non-road	Monthly
MANE-VU	All non-road	Annual
Canada	All non-road	Annual
Mexico	All non-road	Annual

Iowa elected to use the CENRAP-sponsored inventory for all of the non-road categories except for the agricultural equipment categories provided in Table 2-14. For these agricultural equipment categories, Iowa elected to use the Midwest RPO Base K inventory because this inventory provided improvements to the temporal allocation of emissions for the agricultural sector. The Base K inventory includes monthly emissions. The monthly emissions are used in the SMOKE IDA files for modeling.

Table 2-14. Non-road agricultural emissions categories where the MRPO Base K inventory was used instead of the CENRAP inventory in Iowa.

SCC	SCC Description
22600050xx	Off-highway Vehicle Gasoline, 2-Stroke: Agricultural Equipment (2 SCCs);
22650050xx	Off-highway Vehicle Gasoline, 4-Stroke: Agricultural Equipment (11 SCCs);
22670050xx	LPG : Agricultural Equipment (3 SCCs);
22680050xx	CNG : Agricultural Equipment (3 SCCs); and
22700050xx	Off-highway Vehicle Diesel : Agricultural Equipment (11 SCCs).

Texas provided annual and daily emissions for CO, CO₂, NO_x, VOC, SO₂, PM10-FIL, and PM25-FIL for several oil and gas field equipment non-road categories (Table 2-15). Texas provided authorization to change the pollutant codes from PM10-FIL to PM10-PRI and PM25-FIL to PM25-PRI.

Table 2-15. Non-road oil and gas development equipment categories that Texas provided emissions to be used instead of the CENRAP inventory.

SCC	SCC Description
2265010010	Off-highway Vehicle Gasoline, 4-Stroke : Industrial Equipment: Other Oil Field Equipment;
2268010010	CNG : Industrial Equipment : Other Oil Field Equipment; and
2270010010	Off-highway Vehicle Diesel : Industrial Equipment : Other Oil Field Equipment

Lancaster County Nebraska provided its own non-road inventory for SCC 2260000000 (Off-highway Vehicle Gasoline, 2-Stroke : 2-Stroke Gasoline except Rail and Marine: All). The CENRAP-sponsored inventories for SCCs starting with 226 in Lancaster County were removed to correct double-counting of emissions. This adjustment was made by Pechan for Base02b modeling.

2.5.2 Emissions Processing

We configured SMOKE to process all of the non-road mobile emissions inventory data as area-like inventories using spatial surrogates to grid the county-level emissions. As the WRAP inventories contained pre-computed PM emissions, we did not have to use SMOKE to compute coarse mass PM (PMC). The WRAP non-road mobile inventories represented seven-day average emissions (different from the area inventory, which represented weekday average emissions). As actual weekly average emissions, we configured SMOKE to process them by setting WKDAY_NORMALIZE to “No.” For the rest of the non-road mobile inventories we processed the data as weekday average data by setting WKDAY_NORMALIZE to “Yes.” We also assumed that all of the VOC emissions in the inventories are ROG and used SMOKE to convert the VOC to TOG before converting the emissions into CB-IV speciation for the air quality models. We configured SMOKE to create MWSS temporal intermediates rather than daily temporal files because the non-road mobile sources do not use weekly temporal profiles that vary across the weekdays, but do have very different emissions on weekdays versus weekend days.

We divided the non-road mobile emissions modeling based on whether the data were annual or seasonal/monthly inventories. This split facilitated the application of uniform monthly temporal profiles to the seasonal/monthly inventories. After processing the non-road emissions as two separate categories, non-road yearly and non-road monthly, we combined them with the rest of the emissions sectors to create model-ready emissions for CMAQ and CAMx.

To QA the non-road mobile emissions we used the procedures in the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#nr

2.5.3 Uncertainties and Recommendations

We prepared non-road mobile emissions using a combination of inventories having different temporal resolutions and various forms of ancillary data. These different combinations of information may lead to inconsistencies in how these emissions are represented across the modeling domain. In addition, the Canadian inventories contain only province-level information and thus have low-resolution spatial and temporal profiles applied to them. The Mexican non-road emissions are deficient in the number of different SCCs contained in the inventory and the availability of spatial surrogates that are applicable to non-road mobile sources. Improvements to the temporal profiles and spatial surrogates could provide a more consistent approach to representing the non-road emissions across the entire modeling domain.

2.6 Biogenic Sources

Biogenic emissions data for SMOKE consist of input files to the BEIS3 model (EPA, 2004a). BEIS3 is a system integrated into SMOKE for deriving emissions estimates of biogenic gas-phase pollutants from land use information, emissions factors for different plant species, and hourly, gridded meteorology data. The results of BEIS3 modeling are hourly, gridded emissions fluxes formatted for input to CMAQ or CAMx. This section describes the sources of the BEIS3 input data that we used for the Typ02G and Base18G emissions, how we modeled these data and the types of QA that were performed to ensure that SMOKE processed the data as expected.

2.6.1 Data Sources

The BELD3 land use data and biogenic emissions factors that were developed during the WRAP preliminary 2002 modeling were used for the CENRAP biogenic emissions modeling (Tonnesen et al., 2005). These data included BELD3 1-km resolution land use estimates and version 0.98 of the BELD emissions factors. Since the WRAP and CENRAP use the same 36 km Inter-RPO continental U.S. modeling domain, CENRAP was able to leverage of the WRAP work performed previously.

2.6.2 Emissions Processing

We used BEIS3.12 integrated in SMOKE to prepare emissions for the simulations. Most of the preparation for the biogenic emissions processing was completed during the preliminary 2002 modeling (Morris et al., 2005). As the modeling domains did not change from the preliminary 2002 to the final modeling, we re-used the gridded land use data and vegetation emissions factors that we prepared for the preliminary simulations.

To QA the biogenic emissions, we used the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Base02b. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#b3

2.6.3 Uncertainties and Recommendations

The use of newer versions of BEIS (BEIS3.13) and the new MEGAN biogenic emissions models should be considered in future modeling.

2.7 Fire Emissions

Fire emissions data for SMOKE have traditionally been represented as county-level area-source inventories that were placed in only the first vertical model layer. We advanced the representation of fire emissions for air quality modeling by preparing portions of the inventory data as point sources with specific latitude-longitude coordinates for each fire centroid and pre-computed plume rise parameters that were derived from individual fire characteristics. These new inventories were based on the fire data products prepared by a CENRAP emission contractor (Reid et al., 2004b) and modified by the project team to be properly modeled as point sources. These data consist of annual, daily, and hourly IDA-formatted emissions inventory files and ancillary data for allocating the inventories in space, time, and to the Carbon Bond-IV chemistry mechanism used in CMAQ and CAMx. This section describes where we obtained these data, how we modeled them, and the types of QA performed to ensure that SMOKE processed the fire emissions data as expected.

2.7.1 Data Sources

The fire inventories in the Typ02G emissions inventory were held constant through Base18G. We used actual 2002 fire data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory fire data, and actual 2002 fire data for Ontario, Canada. The inventories used consisted of both area and point source data for the U.S., Canada, and Mexico. Sonoma Technology, Inc. provided the fire emissions for the CENRAP states (Reid et al., 2004b). Air Sciences provided us with the WRAP inventories divided among six different fire categories: wildfires, agricultural fires, wildland fire use, natural prescribed, anthropogenic prescribed, and non-Federal rangeland fires (Air Sciences, 2007a). These inventories consisted of annual, daily, and hourly IDA-formatted files with information on daily emissions totals and hourly plume characteristics for each fire. We received similar fire emission inventories for the other RPOS (Air Sciences, 2007b). We modeled these sources with the rest of the stationary-area-source sector.

CENRAP received data for 54 fires that occurred in Ontario during the year 2002. Information on the data code abbreviations, data definitions, and data units used in the raw data files was obtained from Mr. Rob Luik (Data Management Specialist) at the Ontario Ministry of Natural Resources (Rob.Luik@MNR.gov.on.ca). Emissions for each fire were estimated using the Emission Production Model (EPM)/CONSUME within the BlueSky framework. A fire identification code is needed to track individual fires throughout the processing. The unique fire identification code was created for each fire by concatenating the FIRE_NUMBER and CUR_DIST fields of the original data. The fire identification code also contains the FIPS code of the fire; this information is not used by BlueSky but is needed by BlueSky2Inv, the utility program that converts the BlueSky output to the SMOKE inventory format. The FIPS code 135000 was used for all fires with longitudes east of -90° , and FIPS code 135059 was used for

September 2007

fires west of -90° . These FIPS codes were used to ensure that the fires would be assigned the correct time zones in later SMOKE processing. Some of the dates provided in the original data included hourly information. In all cases, the hourly information was not used leaving all data at a daily resolution.

2.7.2 Emissions Processing

SMOKE is instrumented to distribute point-source-formatted fire inventories to the vertical model layers either by using a pre-computed plume rise approach or by computing the plume rise dynamically using actual 2002 meteorology. We applied both approaches for modeling point-source fire emissions in simulation Typ02G. For the pre-computed plume rise approach, SMOKE reads an annual inventory file with information on fire locations, a daily inventory file with daily emission totals for each fire, and an hourly inventory file with hourly plume bottom, plume top, and layer 1 fractions for each fire. SMOKE uses this information to locate the fires on the horizontal model grid and to distribute the plume of each fire vertically to the model layers. Because some of these fires have plumes that reach the model top, we set the number of emissions layers for processing these inventories to the full 19 layers of the meteorology. We applied this approach to the point-source fires for the WRAP, CENRAP and VISTAS regions. The alternative plume rise approach uses information on fuel loading and the heat flux of the fires to distribute the fires vertically to the model layers. The data are provided to SMOKE in the form of an annual inventory with information on fire locations and a daily inventory with daily emission totals for each fire, daily heat flux, and daily fuel loading. We applied this approach to the point-source fires for Ontario, Canada.

All of the point-source fires used diurnal temporal profiles and speciation profiles for VOC and $PM_{2.5}$ developed by Air Sciences (2007a) during the preliminary 2002 modeling (Morris et al., 2005).

We modeled the area-source fires for U.S. and Canada as standard stationary area sources. We applied monthly temporal profiles provided by RPOs, flat weekly temporal profiles, and the diurnal profiles developed by Air Sciences for WRAP fires (Air Sciences, 2007a), and for the rest of the RPOs we used diurnal profiles that were provided by them (Air Sciences, 2007b). We used the forestland area surrogate to distribute these emissions from the county or province level in the inventories to the model grid cells.

To QA the fire emissions, we used the procedure in the CENRAP emissions modeling QA protocol (Environ, 2004) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Typ02G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, annual time-series plots, and vertical profiles. These QA graphics are available at: http://pah.cert.ucr.edu/aqm/cenrap/qa_typ02g36.shtml.

2.7.3 Uncertainties and Recommendations

We used forestland spatial surrogates to distribute these county level (province level for Canada) data to the model grid. Using spatial surrogates to locate fires is a crude approach that results in the artificial smearing of the emissions over too large an area. This issue can be remedied by

moving to a point-source approach for representing these fires, similar to the approach used by Air Sciences for preparing the WRAP fire inventories.

2.8 Dust Emissions

Dust emissions data for SMOKE have traditionally taken the form of county-level stationary-area-source inventories. As these emissions are correlated to meteorology, land use, and vegetative cover, we made several changes to how dust emissions are simulated by SMOKE to take these parameters into consideration. This section describes where we obtained data for windblown, fugitive, and road dust sources, how we modeled them, and the types of QA performed to ensure that SMOKE processed the data as expected.

2.8.1 Data Sources

For the fugitive dust and road dust inventories in the Typ02G emission scenario, we used actual 2002 data developed by the RPOs for the U.S., version 2 of the year 2000 Canadian inventory, and the BRAVO 1999 Mexican inventory. We extracted the fugitive dust inventories from the stationary-area inventories for each of the RPOs, Mexico, and Canada. Before modeling these data we further divided them into construction/mining sources and agricultural sources. We defined the fugitive dust sources in the Base02f modeling based on guidance provided by EPA (2004b). WRAP provide road dust emission inventories (Pollack et al., 2006). For the rest of the RPOs and Canada, we extracted the road dust SCCs from the stationary-area-source inventories. The BRAVO 1999 Mexico inventory did not contain any road dust SCCs. Table 2-16 lists the SCCs for the various fugitive and road dust sources that we modeled in the Base02f and Typ02G inventories. We applied near-source capture transport factors that are based on county-level vegetative cover to the fugitive and road dust inventories to prepare them for input to the air quality models.

For windblown dust, we used gridded emissions prepared outside of SMOKE using a land use and meteorology-based model developed under funding from the WRAP by ENVIRON and UC-Riverside (Mansell, 2005; Mansell et al., 2005).

Table 2-16. Fugitive and road dust SCCs.

Dust Category	SCCs
Fugitive dust (construction and mining)	2275085000, 2311000000, 2311010000, 2311010070, 2311020000, 2311030000, 2325000000, 2305070000, 2530000020, 2530000100, 2530000120
Fugitive dust (agricultural)	2801000003, 2801000005, 2801000008, 2805001000
Road dust	2294000000, 2296000000

2.8.2 Emissions Processing

We modeled the fugitive and road dust inventories through SMOKE using an area-source approach. We modeled these data on the assumption that they represented weekday, rather than seven-day week, emissions and thus used the SMOKE setting WKDAY_NORMALIZE to convert the data to a seven-day average. We configured SMOKE to compute PMC during the

September 2007

processing as (PM₁₀ - PM_{2.5}). Usually the records with dust do not include any other pollutants such as VOC, and NO_x. For the few records that did include pollutants other than the PM we

split the records where the PMs processed with dust and the non PMs processed with the area. We configured SMOKE to create MWSS temporal intermediates rather than daily temporal files because the dust sources do not use weekly temporal profiles that vary across the weekdays.

As noted above, we used SMOKE to apply near-source transport factors to the raw fugitive and road dust inventories to prepare them for input to the air quality models. We used U.S. transport factors from work done by Pace (2005) and a 2001 land use/land cover database to develop a SMOKE input file of county and SCC-based transport factors for the U.S., Canada, and Mexico. We applied these factors to create a new set of inventories adjusted for these transport factors for all regions except VISTAS; the VISTAS dust sources that we received already had the transport factors applied to them.

We calculated the windblown dust emissions outside of SMOKE using an internally developed, process-based model. By “process-based” we refer to an emissions model that integrates information about the processes that lead to the emissions of interest, in this case windblown dust. The process-based windblown dust model developed by the WRAP considers wind speeds, precipitation history, and soil types to derive gridded dust fluxes resulting from wind disturbances for the modeling domain. More information on this model, its modes of operation, and the configuration used for simulation Base02a are available in Mansell et al. (2005).

To QA the fire emissions, we used the procedures in the CENRAP emissions modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for Base02f emissions. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#fd for fugitive dust, http://pah.cert.ucr.edu/aqm/cenrap/qa_base02f36.shtml#rd for road dust, and http://pah.cert.ucr.edu/aqm/cenrap/qa_base02b36.shtml#wbd for windblown dust.

2.8.3 Uncertainties and Recommendations

There are several improvements that should be made to the dust emissions modeling in future simulations. We will expand the list of fugitive dust SCCs that we extract from the stationary-area-source inventories for application of transport factors. This expanded list is based on recent work by EPA (2004b). We will also explore improvements to the assumptions that we used for generating emissions with the WRAP windblown dust model. Areas of improvement in the windblown dust model include refinements to the land use data and soil characteristics, additional information about agricultural activities in the WRAP and CENRAP regions, detailed model evaluation on targeted windblown dust case studies, and the application of snow-cover and vegetative transport factors to these emissions (Mansell et al., 2005).

2.9 Ammonia Emissions

Ammonia (NH₃) emissions from agricultural activities are a major source of ammonia and are dependent on many different environmental parameters, such as meteorology, crop and soil

September 2007

types, and land use. CENRAP developed NH₃ emissions for the CENRAP states (Pechan and CEP, 2005e). Ammonia emissions were estimated for 13 source categories using the Carnegie Mellon University (CMU) model and supplemental technical work; 80% of technical work was dedicated to improving emissions estimates for two source categories—livestock production and fertilizer use. For these two categories, as well as biogenic sources, improvements were made to the activity data and/or emission factors used by the CMU model. For four other source categories (industrial point sources, landfills, ammonia refrigeration, and non-road mobile sources), emissions estimates were prepared independently of the CMU model, and for the remaining six source categories (publicly owned treatment works, wildfires, domestic animals, wild animals, human respiration, and on-road mobile sources), emissions estimates were derived by running the CMU model with no alterations.

CENRAP NH₃ model emissions estimates were combined with data provided by the other RPOs to represent agricultural NH₃ emissions in simulations Typ02G and Base18G.

2.9.1 Data Sources

The WRAP provided NH₃ emissions using the WRAP NH₃ model (Mansell et al, 2005) that generated emissions for the following sectors: domestic sources, wild animals, fertilizers, soils, and livestock. MWRPO provided monthly IDA-formatted inventories reflective of base K to CENRAP that they produced from process-based models of their own, along with temporal profiles and spatial cross-reference information for these sources. Iowa elected to use the MWRPO estimates of NH₃ emissions for fertilizer application, livestock, and wastewater treatment or SCC 28017XXXXX, 28050XXXXX, and 2630020000 respectively. Minnesota reviewed the MWRPO inventory and chose to move forward with the CENRAP developed data set. The rest of the U.S., Canada, and Mexico had agricultural NH₃ emissions contained within their annual stationary-area-source inventories.

2.9.2 Emissions Processing

The WRAP NH₃ emissions were processed outside of SMOKE using the WRAP NH₃ model and provided to CENRAP as gridded, hourly emissions in network common data form (NetCDF) files. CENRAP and MWRPO provided monthly IDA-formatted, county-level NH₃ inventories that were developed separately with process-based models. We modeled these emissions like area sources with SMOKE, applying the temporal profiles and the spatial cross-referencing developed for CENRAP that we received from the MWRPO. The agricultural NH₃ emissions for the rest of the RPOs, Canada, and Mexico are contained within their stationary-area inventories. We applied the SMOKE default temporal profiles and spatial surrogates to all non-process-based NH₃ emissions.

To QA the NH₃ emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulations Typ02G and Base18G. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>

2.9.3 Uncertainties and Recommendations

Like the other emissions categories that have traditionally been represented as stationary area sources, the agricultural NH₃ emissions sector is affected by interregional inconsistencies in the way these emissions are represented.

During the QA of the Base02a emissions, the WRAP discovered a problem with their soil NH₃ estimates. The emission factor for soil NH₃ that were used in developing these data produced too high an emission estimate from this sector. For simulations Base02B through Typ02G, we therefore removed the soil NH₃ sector completely from the WRAP domain. In future simulations we will include these emissions with a revised emission factor for NH₃ emissions from soils.

2.10 Oil and Gas Emissions

Emissions from oil and gas development activities have been poorly characterized in the past. Simulations These emissions have been sporadically reported by some states in their stationary-area-source inventories, but for the most part were missing from our preliminary modeling. In the Typ02G and Base18G simulations, significant effort was made to better represent oil and gas production emissions explicitly as both area and point sources.

2.10.1 Data Sources

Emissions from oil and gas production activities for the CENRAP states were included with the other CENRAP state emission source categories (Pechan and CEP, 2005e). We received oil and gas production emissions inventories for the WRAP states and for tribal lands in the WRAP region as stationary-area-source and stationary-point-source IDA-formatted inventories. ERG, Inc. provided the point-source inventories with the rest of the stationary-point data (ERG, 2006a). ENVIRON provided the area-source oil and gas inventories for non-CA WRAP states and for tribal lands in the WRAP region, along with spatial surrogates for allocating these data to the model grid (Russell and Pollack. 2005). Oil and gas production emissions data for outside of the WRAP region are contained in the stationary-area inventories.

2.10.2 Emissions Processing

We modeled the WRAP point-source oil and gas production emissions in combination with the rest of the stationary-point-source emissions. We modeled the WRAP area-source oil and gas production emissions explicitly as a separate category that included WRAP and tribal inventories. These data represent weekly average emissions and did not require any renormalization within SMOKE. We used spatial surrogates generated by ENVIRON to allocate these annual county-level emissions to the model grid. For all oil and gas emissions, we applied flat temporal profiles to create hourly inputs to CMAQ and CAMx.

2.10.3 Uncertainties and Recommendations

In future 2002 modeling California oil and gas production emissions should be replaced with revised data provided by the California Air Resources Board (CARB). In addition, WRAP has

September 2007

updated their oil and gas production inventory for the base and future years in a Phase II work effort that substantially improved the emissions inventory estimates (Bar-Ilan et al., 2007).

2.11 MMS Off-shore Gulf of Mexico Emissions

Offshore area point source emissions include emissions in the Gulf of Mexico and off the coast of California that are associated with oil and gas drilling platforms.

2.11.1 Data Sources

We obtained year 2000 IDA-formatted point-source inventories for oil and gas platforms in the Gulf of Mexico from the Minerals Management Service (MMS) web site:

http://www.gomr.mms.gov/homepg/regulate/environ/airquality/gulfwide_emission_inventory/2000GulfwideEmissionInventory.html

We combined these with point-source data for coastal California provided to us by CARB during the preliminary 2002 modeling. We also obtained gridded area source emissions for platforms in the Gulf of Mexico from the MMS that we converted to the CENRAP 36-km model grid.

The 2000 MMS Gulf wide Emission Inventory was updated as of June 2006 to account for a change in vessel emissions in the non-point source (non-platform) database file. The point source (platform) emission inventory database file has not changed from the original version. Area source emissions from offshore activities in the Gulf of Mexico were developed from the latest estimates provided by the Minerals Management Service (MMS). The MMS inventory includes both platform and non-platform sources. The non-platform area source emissions estimates are spatially allocated to lease blocks and protraction units throughout the Gulf of Mexico. Temporal and spatial allocation cross-reference data were developed from the MMS inventory data and formatted for input to the SMOKE emissions model by Carolina Environmental Programs. These data were provided to the CENRAP emissions modeling team for implementation within SMOKE. The spatial allocation surrogates were provided for 4-km grid cells. The UCR team used these surrogates and developed surrogates for 36-km grid cells. Because these data are references to lease blocks/protraction units, rather than counties, this source category was processed separately from all other emissions using a customized reference data and SMOKE run scripts.

We modeled the offshore point and area sources as separate categories in the simulations. We used SMOKE to locate the offshore point sources on the model grid and to vertically allocate them into 15 model layers.

To QA the offshore platform emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 20042) and a suite of graphical summaries. We used tabulated summaries of the input data and SMOKE script settings to document the data and configuration of SMOKE for simulation Base02a. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml> for the point and area sources.

2.11.2 Uncertainties and Recommendations

While the MMS data that we used were an improvement over previously modeled Gulf of Mexico platform inventories, the data were developed for a different modeling application that covered only the extreme northwestern portion of the Gulf, so they are missing large areas of the region of the Gulf that contain drilling platforms. The California offshore inventory represents an initial attempt at compiling an emission inventory for this area and contains very few sources. Future simulations will focus on improving these emissions by expanding the coverage of the offshore platform inventories for both the Gulf of Mexico and the Pacific Coast.

2.12 Off-shore Shipping Emissions

Emission inventory development for regional- and continental-scale air quality modeling has historically neglected offshore emissions sources beyond 25 miles offshore. Concern over the environmental effects of commercial shipping emissions in the Pacific on the coastal states in the WRAP region led to the development of a commercial marine shipping inventory for the Pacific. This inventory of off-shore marine vessels emissions made a substantial difference in some of the coastal western PM estimates (e.g., SO₄). VISTAS developed an off-shore marine vessels inventory for the entire modeling domain that included the Pacific and Atlantic Oceans and the Gulf Of Mexico. For Typ02G and Base18G emission inventories CENRAP adopted the offshore shipping inventories developed by VISTAS.

2.12.1 Data Sources

Initially we obtained gridded annual commercial marine shipping emissions for the Pacific on the 36-km model grid from WRAP for inclusion in CENRAP simulations in the Base F modeling (Pollack et al., 2006). The commercial marine inventory contains all of the criteria pollutants contained in the non-road mobile-source inventory: CO, NO_x, VOC, NH₃, SO₂, PM₁₀, and PM_{2.5}. This inventory was subsequently updated in the Typ02G and Base18G modeling with the VISTAS off-shore commercial marine emissions inventory that covered the Gulf of Mexico and the Atlantic and Pacific Oceans and was based on the EPA/ARB SO_x Emissions Control Area (SECA) program. Dr. James Corbett (University of Delaware) analyzed off-shore marine vessel data and worked with ENVIRON/ICF to convert to gridded emissions for the SECA grid. ENVIRON then provided SO₂, NO_x, PM and VOC emissions for the RPO 36-km grid.

2.12.2 Emissions Processing

The commercial marine shipping inventory was not processed through SMOKE. VISTAS provided the data to the as gridded text files on the 36-km model grid. These data were reformatted to the NetCDF CMAQ input format with a utility developed by UCR. The VOC inventory was converted to CB-IV speciation and the NO_x and PM_{2.5} inventory pollutants to CMAQ input species with SMOKE chemical profiles for commercial shipping sources. No temporal adjustments were applied to these emissions; they use uniform monthly, daily, and diurnal profiles. An SCC for commercial marine vessels within the MMS inventory (SCC CM80002200) was accounted for in the commercial marine inventory developed for VISTAS. The duplicate emissions were removed from the MMS inventory prior to processing emissions

September 2007

for Base G simulations. The duplicated emissions amounted to 19,000 TPY of NO_x and 3,184 TPY of SO₂. For simulation Typ02G and Base18G we received binary netCDF file from ENVIRON for one day and that day was used for every day of the year.

To QA the commercial marine shipping emissions, we used the procedures in the CENRAP modeling QAPP (Morris and Tonnesen, 2004) and Modeling Protocol (Morris et al., 2004a) and a suite of graphical summaries. The graphical QA summaries include, for all emissions output species, daily spatial plots, daily time-series plots, and annual time-series plots. These QA graphics are available at <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>.

2.12.3 Uncertainties and Recommendations

As a first attempt at representing shipping emissions in the Pacific in international waters, the WRAP and VISTAS 2002 commercial shipping inventory is a breakthrough in a historically neglected emissions category. As the RPOs evaluate the effects of these emissions on the air quality modeling, we anticipate that there will be refinements to the temporal profiles and to the vertical allocation of the emissions. Many of the stacks of large commercial ships contained in this inventory extend vertically above the first model layer. Future versions of this inventory should use higher-resolution temporal adjustments and should allocate the emissions to the appropriate model layers. Off-shore marine shipping activity is projected to increase. However, there are also the potential for emission controls on this source category (e.g., SECA program). Given these two off setting activities, the 2002 off-shore marine shipping emissions were assumed to be unchanged going from 2002 to 2018. Better estimates of 2018 marine emissions are being developed that should be considered in future modeling activities.

2.13 2018 Growth and Control

Base18G was based on grown inventories assuming on-the-books control strategies. CENRAP contracted with Pechan to deliver growth and control data for CENRAP and to consolidate growth and control information for other RPOs where available (Pechan, 2005d). The data are applicable to all source categories and pollutants included in the CENRAP 2002 emission inventory. This includes the following pollutants: sulfur oxides (SO_x), oxides of nitrogen (NO_x), volatile organic compounds (VOC), carbon monoxide (CO), ammonia (NH₃), and primary PM₁₀ and PM_{2.5}. Some source categories were held constant between 2002 and 2018 because either stagnant growth was deemed appropriate or insufficient data was available to adequately project future growth or controls. These source categories include the following:

- Wind Blown Dust from non-agricultural land use categories.
- Emissions from wildfires.
- Emissions from Mexico.
- Global transport sources (i.e., the 2002 GEOS-CHEM boundary conditions).

2.13.1 Data Sources

CENRAP contracted with Pechan to provide growth and control factors to be applied with SMOKE for the CENRAP region (Pechan, 2005d). These growth and control parameters were based on growth estimates derived from EGAS 5.0 and control estimates assumed for

September 2007

implementation of federal regulations and on-the-books state and local control programs. Emissions projections for electric generating units were developed for the RPOs with the Integrated Planning Model (IPM). The RPO 2.1.9 IPM results were subsequently modified by VISTAS, MRPO and CENRAP to reflect planned new construction and controls. The WRAP provided 2018 EGU estimates developed in coordination with State and Industry stakeholders. VISTAS, MWRPO and the WRAP provided emissions for 2018, having applied growth and control factors outside of SMOKE processing. EPA provided SMOKE processed emissions, applying both growth and controls, for Canada for the year 2020. These emissions were provided on the RPO 36-km grid. However, emissions were inexplicably processed for an alternative vertical structure. Alpine Geophysics, under contract to VISTAS reallocated the emissions through the vertical layers to more accurately reflect the vertical structure applied uniformly by the RPOs. The modified data was obtained directly from Alpine Geophysics. Emissions from Mexico were held constant between the inventory year 1999 and modeled 2002 and 2018. Improvements to the Mexican inventory have been continuously made between generation of the original BRAVO inventory and the present improved 1999 inventory. However, given the continued uncertainties in the improved inventory, no future year projections were attempted by CENRAP.

2.13.2 Emissions Processing

Growth and control factors developed by Pechan (2005d) for Arkansas did not match the final delivered inventory for Arkansas. Arkansas underwent major revisions to point and facility IDs in mid-2005. These updates were not available by the delivery date of the growth and control parameters. In coordination with Arkansas, a cross-walk was developed to correct the point and facility IDs.

The assumptions that went into the development of controls for engines covered under the RICE MACT were not consistent with the final rule. Rule penetration values for CENRAP states were adjusted to more accurately reflect the impact of the final rule.

The impact of the refinery global settlements was not incorporated into CENRAP modeling until the base G simulations. Control assumptions provided by EPA and referenced in EPA CAIR modeling were applied to the 2018 inventory. These reductions primarily impacted SO₂ emissions; however, NO_x reductions were applied in Oklahoma, Louisiana, and Minnesota.

2.13.3 Uncertainties and Recommendations

The impact of control programs is an area of uncertainty that will need continued review as the programs are implemented. Development of growth and control assumptions for Mexico will be necessary for continued refinement of the impact of international transport. CENRAP obtained estimates of increased prescribed burn activity for the Forest Service after processing of the base G simulations was underway. These estimates of increased activity should be reviewed for inclusion in future simulations. EPA developed 2020 estimates of Canadian emissions are assumed to include erroneous stack parameters previously addressed in the 2000 emissions processing. Further review of this data set is recommended.

2.14 2018 Base G C1 Control Sensitivity

CENRAP conducted a control sensitivity evaluating the impact of point source reductions given a maximum dollar per ton control level. The intent of the control sensitivity was to generate information on the impact of possible control strategies in support of the consultation process. The strategies were grouped together under a common set of criteria and not specifically identified by the states. The results of the modeling were not intended to be prescriptive; instead, they were intended to be a starting point for control discussions that would require much greater refinement.

2.14.1 Data Sources

CENRAP contracted with Alpine Geophysics to provide an evaluation of possible additional controls for the 2018 CENRAP point source inventory. These controls were in addition to on-the-books and BART controls assumed in the development of Base18F and Base18G emission scenarios. Base18F IDA files were enhanced with additional information on base level controls. The enhanced dataset was then linked with the control data contained in the 2006 release of EPA's AirControlNet software. Alpine developed cost curves for NO_x and SO₂ in 2005 dollars for the Base18F CENRAP point source inventory. Staff from Iowa DNR and Kansas DHE worked in conjunction to add area of influence data (Alpine Geophysics, 2006) and distance calculations to each Class I area in CENRAP. A variety of dollar per ton control levels were evaluated. CENRAP elected to base the sensitivity on a maximum control cost of \$5,000 per ton. This selection was made with the understanding that the cost data under-represented the true cost of retrofit controls and did not take in to consideration more recent market fluctuations impacting costs of controls and construction. CENRAP refined the selection by applying controls to only those sources that met the criteria that the ratio of their emissions in tons per year to their distance to any Class I area in kilometers be less than 5. This distance weighting criteria allowed the sensitivity to focus on those sources with the greatest impact. Additional controls for other RPOs were not considered in this evaluation.

2.14.2 Emissions Processing

Sources considered for control were removed from the IDA files. Growth and control assumptions were applied outside of SMOKE and delivered to UCR as 2018 emissions. Stack parameter changes as a result of additional controls were not considered in this analysis.

2.14.3 Uncertainties and Recommendations

Given uncertainties in control costs more refined analyses should include an evaluation of retrofit control costs under present values.

2.15 Emissions Summaries

Appendix B provides details on the source of the emission files used in the CENRAP Typ02G and Base18G modeling. Also in Appendix B are sample emission summary plots, additional plots are available on the CENREAP modeling website:

<http://pah.cert.ucr.edu/aqm/cenrap/emissions.shtml>.

CENRAP has contracted with E.H. Pechan and Associates to provide emissions summaries used in the final Typ02G and Base18G modeling in Excel spreadsheets and in an Access database that are available on the CENRAP website (<http://www.cenrap.org/projects.asp#>). Figures 2-3 through 2-9 display the, respectively, SO₂, NO_x, VOC, PM_{2.5}, PM₁₀, NH₃ and CO anthropogenic emissions for the CENRAP states and the Typ02G and Base18G emission scenarios. Emissions are broken down by major source sector. For the state of Texas the emissions are broken by three groups, northeast Texas, southeast Texas and remainder of Texas (west Texas).

For most states, EGUs are the largest contributor to SO₂ emissions (Figure 2-3). As EGU SO₂ emissions are generally projected to be reduced in the future, most states show a reduction in total SO₂ emissions from 2002 to 2018. One exception to this is Louisiana for which non-EGU point source SO₂ emissions are greater than for EGU and are projected to increase from 2002 to 2018. The reasons for these increases are unclear, but the growth factors for non-EGU points should be examined more carefully.

NO_x emissions are fairly evenly distributed across non-EGU point, EGU point, non-road mobile, on-road mobile and area sources for the 2002 Typ02G emissions scenario (Figure 2-4). In 2018, the contributions of on-road mobile source NO_x emissions is reduced dramatically, with some states also showing reductions in EGU NO_x emissions as well, resulting in all states exhibiting lower NO_x emissions in 2018 than 2002.

VOC emissions are dominated by area, non-road mobile, on-road mobile and non-EGU point sources in both 2002 and 2018 (Figure 2-5). VOC emissions from on-road and non-road mobile source are projected to go down in the future, whereas VOC emissions from non-EGU point and, especially, area sources are projected to increase. Thus, whether a state's total VOC emissions increase or decrease depends on the relative contributions of mobile versus area sources and the level of increase in area source VOC emissions. Note that the VOC emissions listed in Figure 2-5 do not include biogenic VOC emissions that would be greater than the anthropogenic VOC emissions shown in Figure 2-5. Note that because biogenic VOC emissions are processed using the SMOKE/BEIS module on the 36 km grid, state-wide biogenic VOC emissions summaries are not readily available.

Primary PM_{2.5} emissions are primarily from road dust and fugitive dust, and for some states fires (Figure 2-6). Kansas, Oklahoma, Louisiana and Texas all have large contributions from fires not seen in the other states. Road dust and fugitive dust are the most dominate source categories for coarse particulate as well (Figure 2-7).

CENRAP developed a separate ammonia emissions for 13 categories using the CMU model including livestock and fertilizer that dominates the ammonia emissions across the CENRAP

states (Figure 2-8). Several states also have significant ammonia contributions from non-EGU point sources, whereas others do not.

CO emissions are dominated by the on-road and non-road mobile source sectors (Figure 2-9). However, states with fires also see large CO contributions from them as well. On-road mobile source CO emissions are projected to go down substantially from 2002 to 2018, whereas the other source categories are flat.

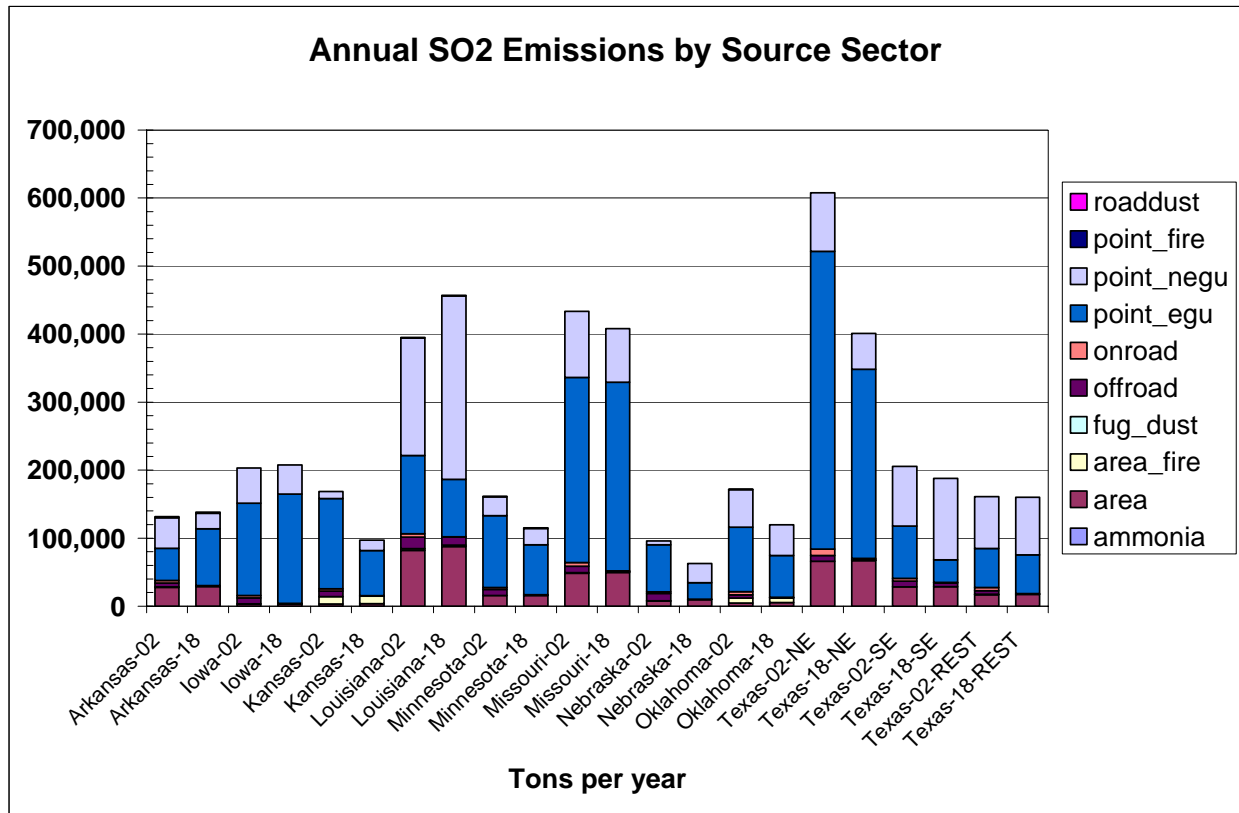

Figure 2-3. Summary of Typ02G and Base18G SO2 emissions by CENRAP state and major source sector (tons per year).

Figure 2-4. Summary of Typ02G and Base18G NOx emissions by CENRAP state and major source sector (tons per year).

Figure 2-6. Summary of Typ02G and Base18G PM2.5 emissions by CENRAP state and major source sector (tons per year).

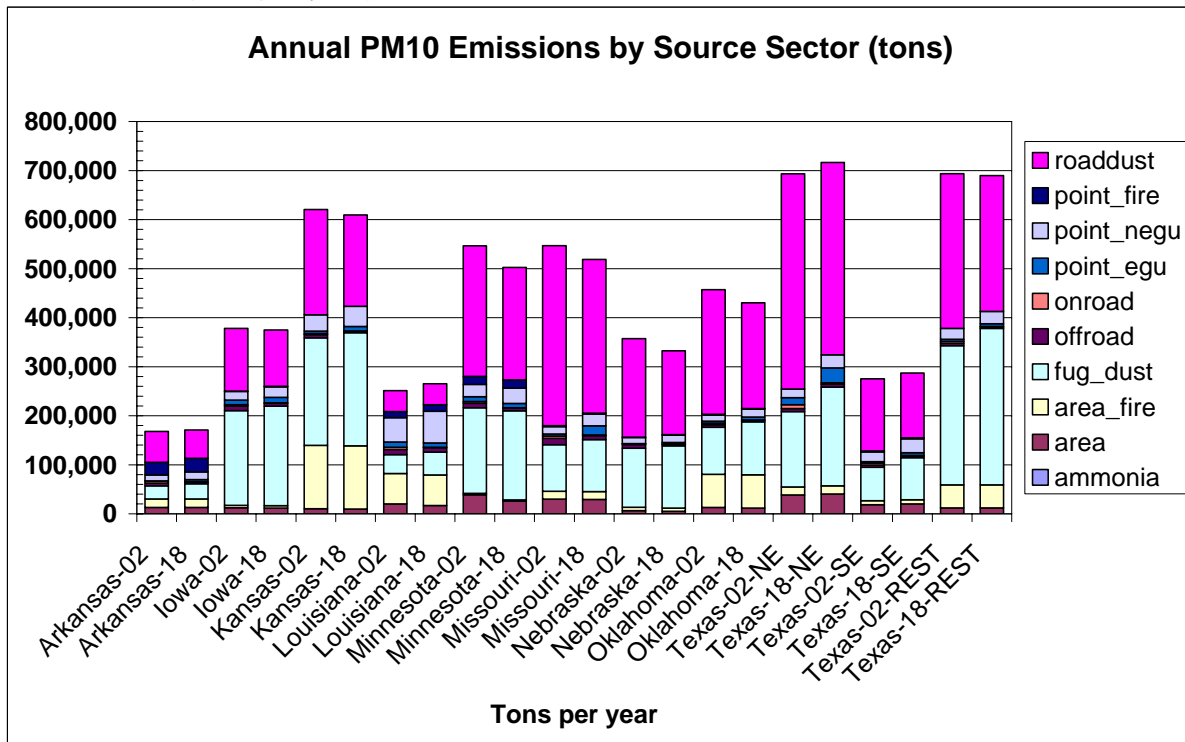

Figure 2-7. Summary of Typ02G and Base18G PM10 emissions by CENRAP state and major source sector (tons per year).

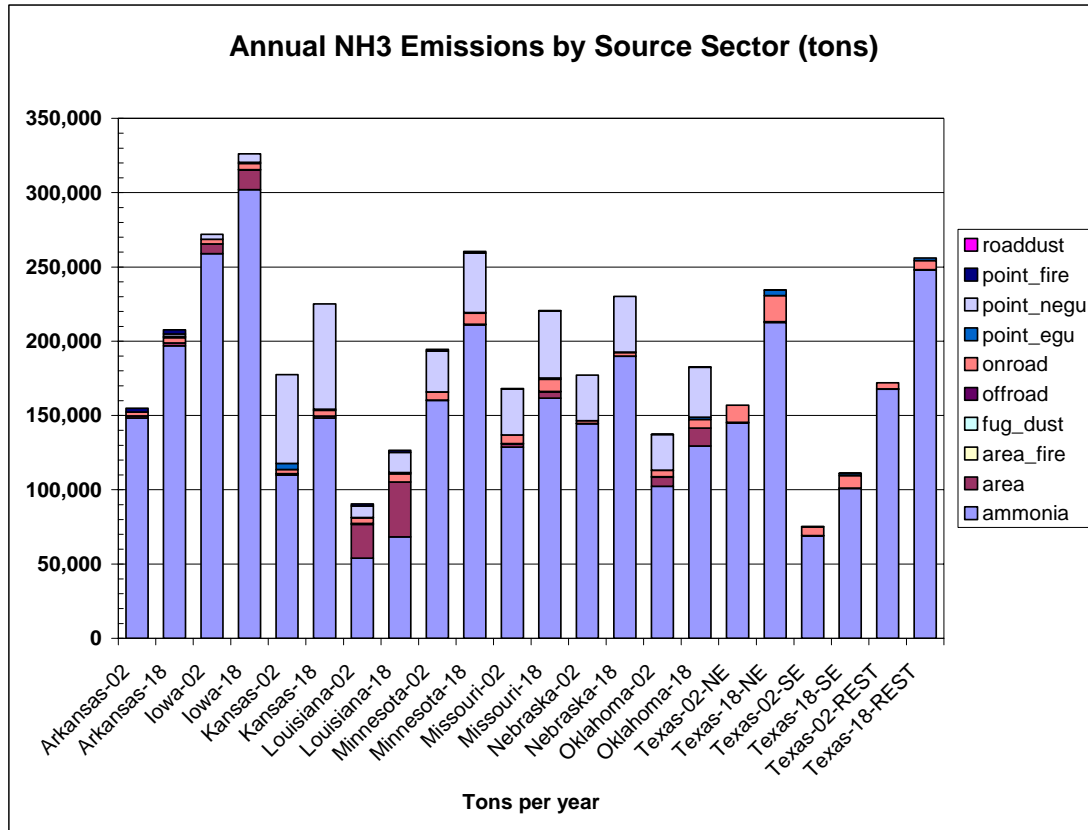

Figure 2-8. Summary of Typ02G and Base18G NH3 emissions by CENRAP state and major source sector (tons per year).

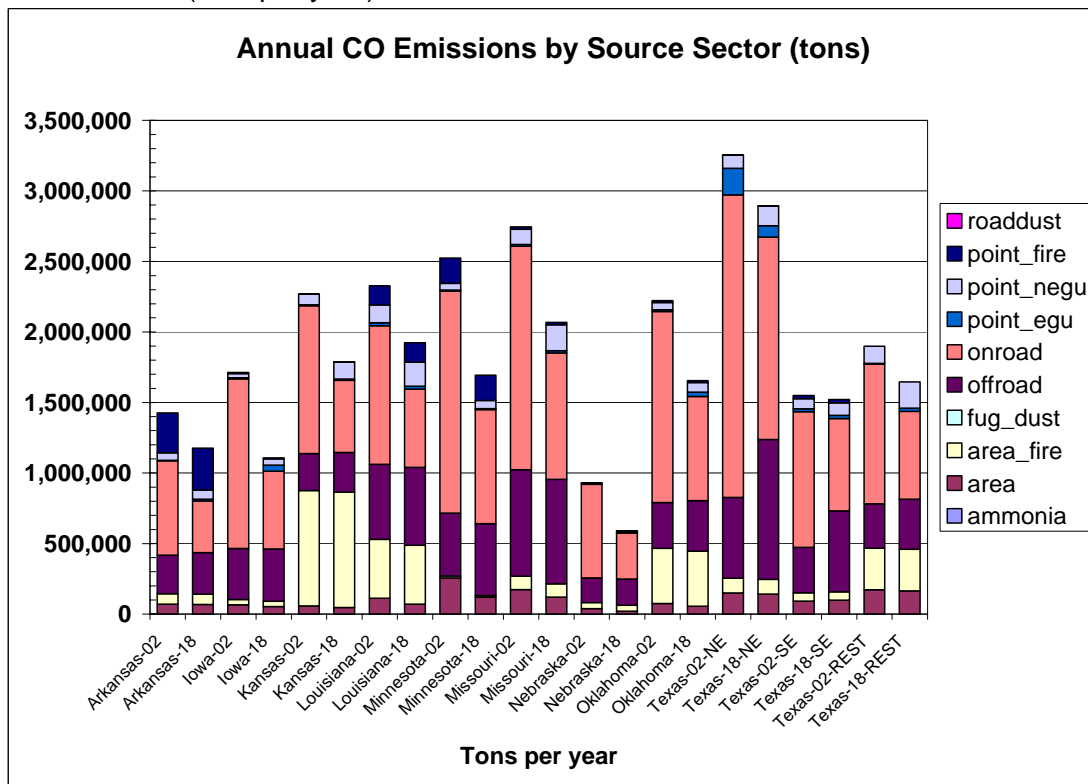

Figure 2-9. Summary of Typ02G and Base18G CO emissions by CENRAP state and major source sector (tons per year).

3.0 MODEL PERFORMANCE EVALUATION

In this Chapter we summarize the CMAQ model performance for the final 2002 36 km Base F base case simulation. Because the 2002 Base F CMAQ simulation produced nearly identical results in the U.S. as the final 2002 Base G simulation and limited resource availability, CENRAP elected not to redo the model evaluation for the 2002 Base G case. This model performance focuses on the ability of the model to predict PM species within the CENRAP region. Details on the model performance are provided in Appendix C. Previously we have documented model performance of interim versions of model base case simulations in reports (Morris et al., 2005) and presentations to the CENRAP Work Groups and POG (e.g., Morris et al., 2006a,b).

3.1 Evaluation Methodology

EPA's integrated ozone, PM_{2.5} and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007). The CMAQ model performance evaluation effort focused on the first two components, namely:

- **Operational Evaluation:** Tests the ability of the model to estimate PM concentrations (both fine and coarse) and the components at PM₁₀ and PM_{2.5} including the quantities used to characterize visibility (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon, other PM_{2.5}, and coarse matter (PM_{2.5-10})). This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting “the right answer for the right reason”; and
- **Diagnostic Evaluation:** Tests the ability of the model to predict visibility and extinction, PM chemical composition including PM precursors (e.g., SO_x, NO_x, and NH₃) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

In this final model performance evaluation for the 2002 Typical Base F CMAQ simulation, the operational evaluation has been given the greatest attention since this is the primary thrust of EPA's modeling guidance. However, we have also examined certain diagnostic features dealing with the model's ability to simulate sub-regional, monthly, diurnal, gas phase and aerosol concentration distributions. In the course of the CENRAP air quality modeling and other modeling processes, numerous diagnostic sensitivity tests were performed to investigate and improve model performance. Key diagnostic tests that were performed and the results are discussed on the CENRAP modeling website: <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>.

3.2 Ambient Air Quality Data used in the Evaluation

The ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The first is the routine gas-phase concentration measurements for ozone, SO₂, NO₂ and CO archived in EPA's Aerometric Information Retrieval System (AIRS) Air Quality System (AQS) database. Other sources of observed information come from the various PM monitoring networks in the U.S. These include the Interagency Monitoring of Protected Visual Environments (IMPROVE); Clean Air Status and Trends Network (CASTNET); EPA Speciation Trends Network (STN) of PM_{2.5} species; and National Acid Deposition Program (NADP). During the course of the CENRAP modeling, the numerous base case simulations were evaluated across the continental U.S. (e.g., Morris et al., 2005). In this section and in Appendix C we focus our evaluation on model performance within the CENRAP region.

3.2 Operational Model Evaluation Approach

The CENRAP modeling databases will be used to develop the visibility State Implementation Plan (SIP) as required by the Regional Haze Rule (RHR). Accordingly, the primary focus of the operational evaluation in this report is on the six components of fine particulate (PM_{2.5}) and coarse mass (PM_{2.5-10}) within the CENRAP region that are used to characterize visibility at Class I areas:

- Sulfate (SO₄);
- Particulate Nitrate (NO₃);
- Elemental Carbon (EC);
- Organic Mass Carbon (OMC);
- Other inorganic fine particulate (IP or Soil); and
- Coarse Mass (CM).

The model performance for ozone, precursors, and product species (e.g., SO₄, NO₃, NH₄ and HNO₃) is also evaluated to build confidence that the modeling system is sufficiently reliable to project future-year visibility.

3.3 Model Performance Goals and Criteria

The issue of model performance goals for PM species is an area of ongoing research and debate. For ozone modeling, EPA has established performance goals for 1-hour ozone: normalized mean bias and gross error of #±15% and #35%, respectively (EPA, 1991). EPA's draft fine particulate modeling guidance notes that performance goals for ozone should be viewed as upper bounds of model performance that PM models may not be able to always achieve and that we should demand better model performance for PM components that make up a larger fraction of the PM mass than those that are minor contributors (EPA, 2001). EPA's final modeling guidance does not list any specific model performance goals for PM and visibility modeling and instead provides a summary of PM model performance across several historical applications that can be used for comparisons, if desired. Measuring PM species is not as precise as ozone monitoring. In fact, the uncertainty in measurement techniques for some PM species is likely to

exceed the more stringent model performance goals, such as those for ozone. For example, recent comparisons of the PM species measurements using the IMPROVE and STN measurement technologies found uncertainties of approximately $\nabla 20\%$ (SO₄) to $\nabla 50\%$ (EC) (Solomon et al., 2004).

For the CENRAP modeling we have adopted three levels of model performance goals and criteria for bias and gross error as listed in Table 3-1. Note that we are not suggesting that these performance goals be adopted as guidance. Rather, we are just using them to frame and put the PM model performance into context and to facilitate model performance intercomparison across episodes, species, models and sensitivity tests.

Table 3-1. Model performance goals and criteria used to assist in interpreting modeling results.

Fractional Bias	Fractional Gross Error	Comment
# $\nabla 15\%$	# 35%	Ozone model performance goal for which PM model performance would be considered “good” – note that for many PM species measurement uncertainties may exceed this goal.
# $\nabla 30\%$	# 50%	Proposed PM model performance goal that we would hope each PM species could meet
# $\nabla 60\%$	# 75%	Proposed PM criteria above which indicates potential fundamental problems with the modeling system.

As noted in EPA’s PM modeling guidance, less abundant PM species should have less stringent performance goals (EPA, 2001; 2007). Accordingly, we are also using performance goals that are a continuous function of average concentrations, as proposed by Dr. James Boylan at the Georgia Department of Natural Resources (GA DNR), that have the following features (Boylan, 2004):

- Asymptotically approaching proposed performance goals or criteria (i.e., the $\nabla 30\%/50\%$ and $\nabla 60\%/75\%$ bias/error levels listed in Table 3-1) when the mean of the observed concentrations are greater than 2.5 ug/m³.
- Approaching 200% error and $\nabla 200\%$ bias when the mean of the observed concentrations are extremely small.

Bias and error are plotted as a function of average concentrations. As the mean concentration approaches zero, the bias performance goal and criteria flare out to $\nabla 200\%$ creating a horn shape, hence the name “Bugle Plots”. Dr. Boylan has defined three Zones of model performance: Zone 1 meets the $\nabla 30\%/50\%$ bias/error performance goal and is considered “good” model performance; Zone 2 lies between the $\nabla 30\%/50\%$ performance goal and $\nabla 60\%/75\%$ performance criteria and is an area where concern for model performance is raised; and Zone 3 lies above the $\nabla 60\%/75\%$ performance criteria and is an area of questionable model performance.

3.4 Key Measures of Model Performance

Although we have generated numerous statistical performance measures (see Table C-2 in Appendix C) that are available on the CENRAP modeling website, when comparing model performance across months, subdomains, networks, grid resolution, models, studies, etc. it is useful to have a few key measurement statistics to be used to facilitate the comparisons. It is also useful to have a subset of months within the 2002 year that can represent the entire year so that a more focused evaluation can be conducted. We have found that the Mean Fractional Bias and Mean Fractional Gross Error appear to be the most consistent descriptive measure of model performance (Morris et al., 2004b; 2005). The Fractional Bias and Error are normalized by the average of the observed and predicted value (see Table C-2) because it provides descriptive power across different magnitudes of the model and observed concentrations and is bounded by -200% to +200%. This is in contrast to the normalized bias and error (as recommended for ozone performance goals, EPA, 1991) that is normalized by just the observed value so can “blow up” to infinity as the observed value approaches zero. In Appendix C we perform a focused evaluation of model performance for PM and gaseous species and four months of the 2002 year that are used to represent the seasonal variation in performance:

- January
- April
- July
- October

Scatter plots of model predictions and observations for each PM species are presented for each of the four months along with performance statistics and predicted and observed time series plots at each CENRAP Class I area. Summary plots of monthly fractional bias and error are also presented.

3.5 Operational Model Performance Evaluation

A summary of the operational evaluation is presented below. Just the monthly fractional bias performance metrics for each PM species using bar charts and Bugle Plots are presented in this section. The reader is referred to Appendix C for the complete model performance evaluation.

3.5.1 Sulfate (SO₄) Model Performance

Figure 3-1 compares the monthly SO₄ fractional bias across the CENRAP region for the IMPROVE, STN and CASTNet monitoring networks. An underprediction bias is clearly evident the first 8-10 months of the year. This underestimation bias is greatest across the CASTNet network which persists throughout the year. The SO₄ underprediction is not as severe for the STN network and it is minimal by August becoming a slight overprediction in September. For the IMPROVE network, the SO₄ fractional bias is $< \pm 20\%$ for the first 2 and last 3 months of the year and ranges from -30% to -50% for the late Spring and Summer months.

Figure 3-1 also includes a Bugle Plot of monthly SO₄ fractional bias statistics (for Bugle Plot of fractional gross error see Appendix C) and compares them against the proposed PM model

performance goal and criteria (see Table 3-1). For the STN network, SO₄ model performance meets the proposed performance goal for all months. For the IMPROVE network, approximately half of the months achieve the proposed PM performance goal with the other half outside of the goal, but within the performance criteria. Across the CASTNet network, most months are outside of the proposed goal but are within the criteria. The CASTNet fractional bias for some months is right at the performance criteria ($\leq \pm 60\%$). With the exception of two IMPROVE months, the monthly SO₄ fractional bias performance statistics achieve the proposed PM model performance goal.

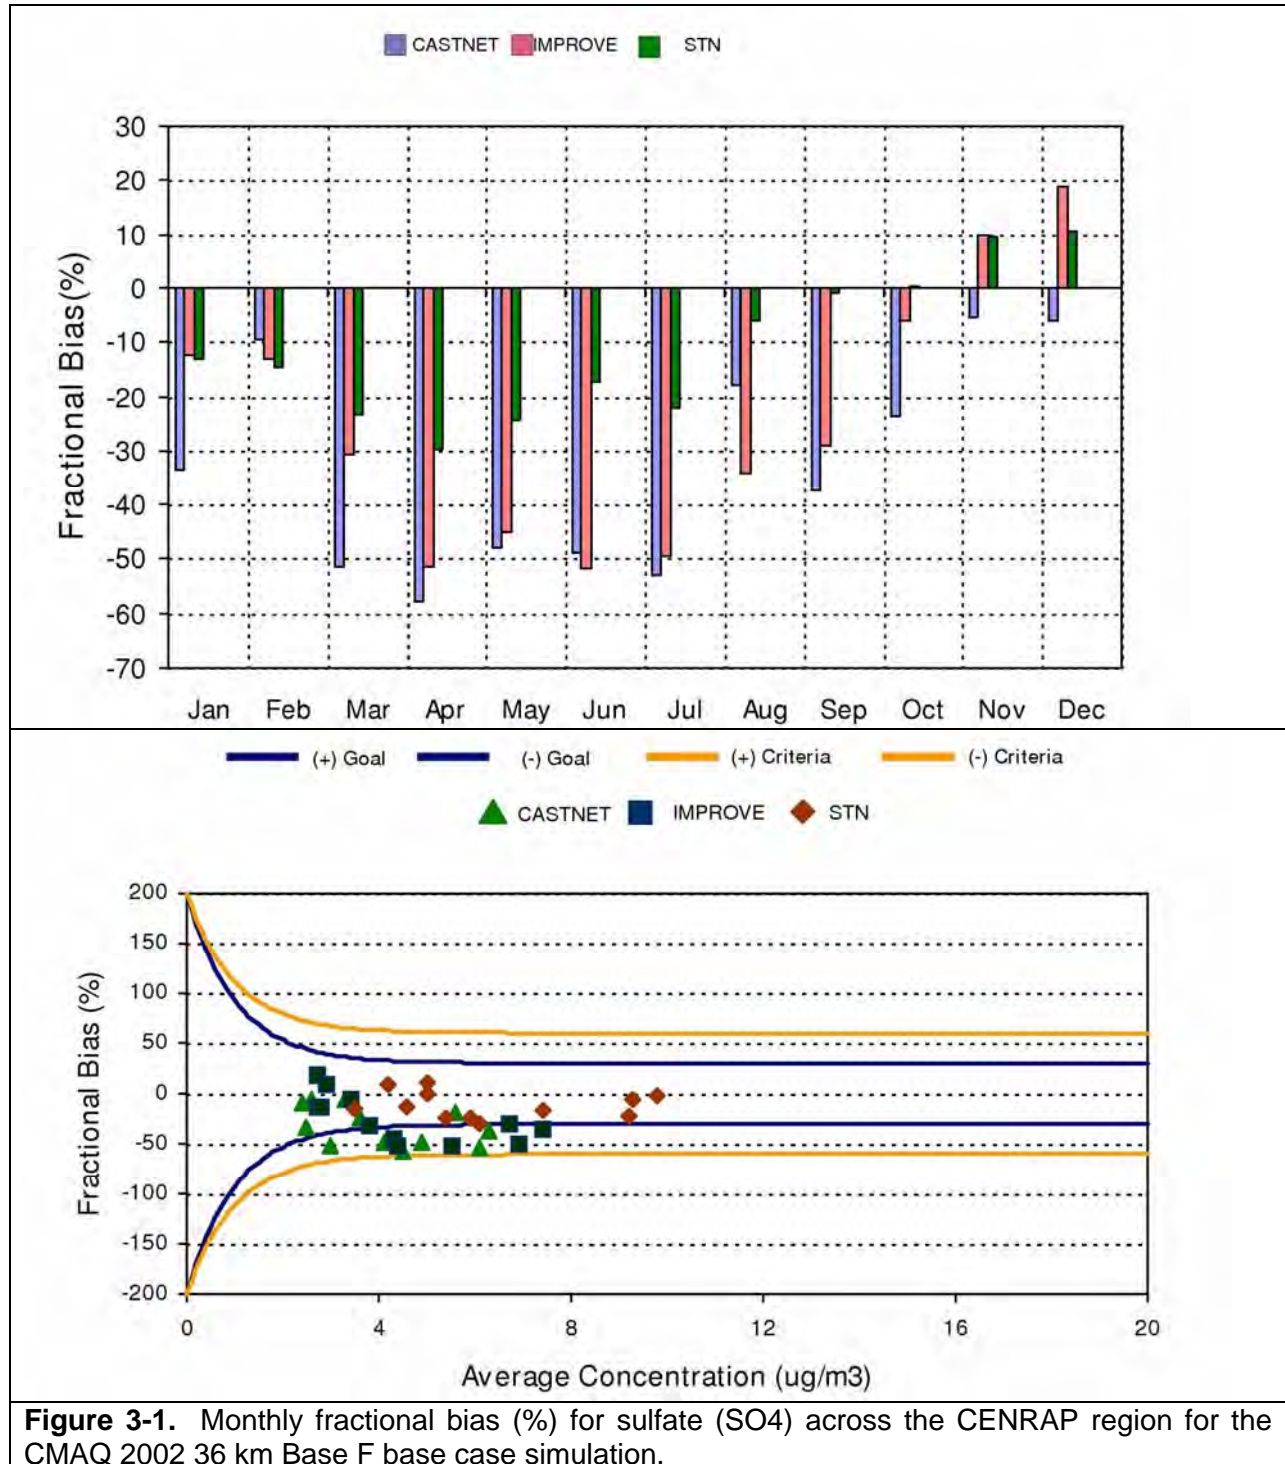

3.5.2 Nitrate (NO₃) Model Performance

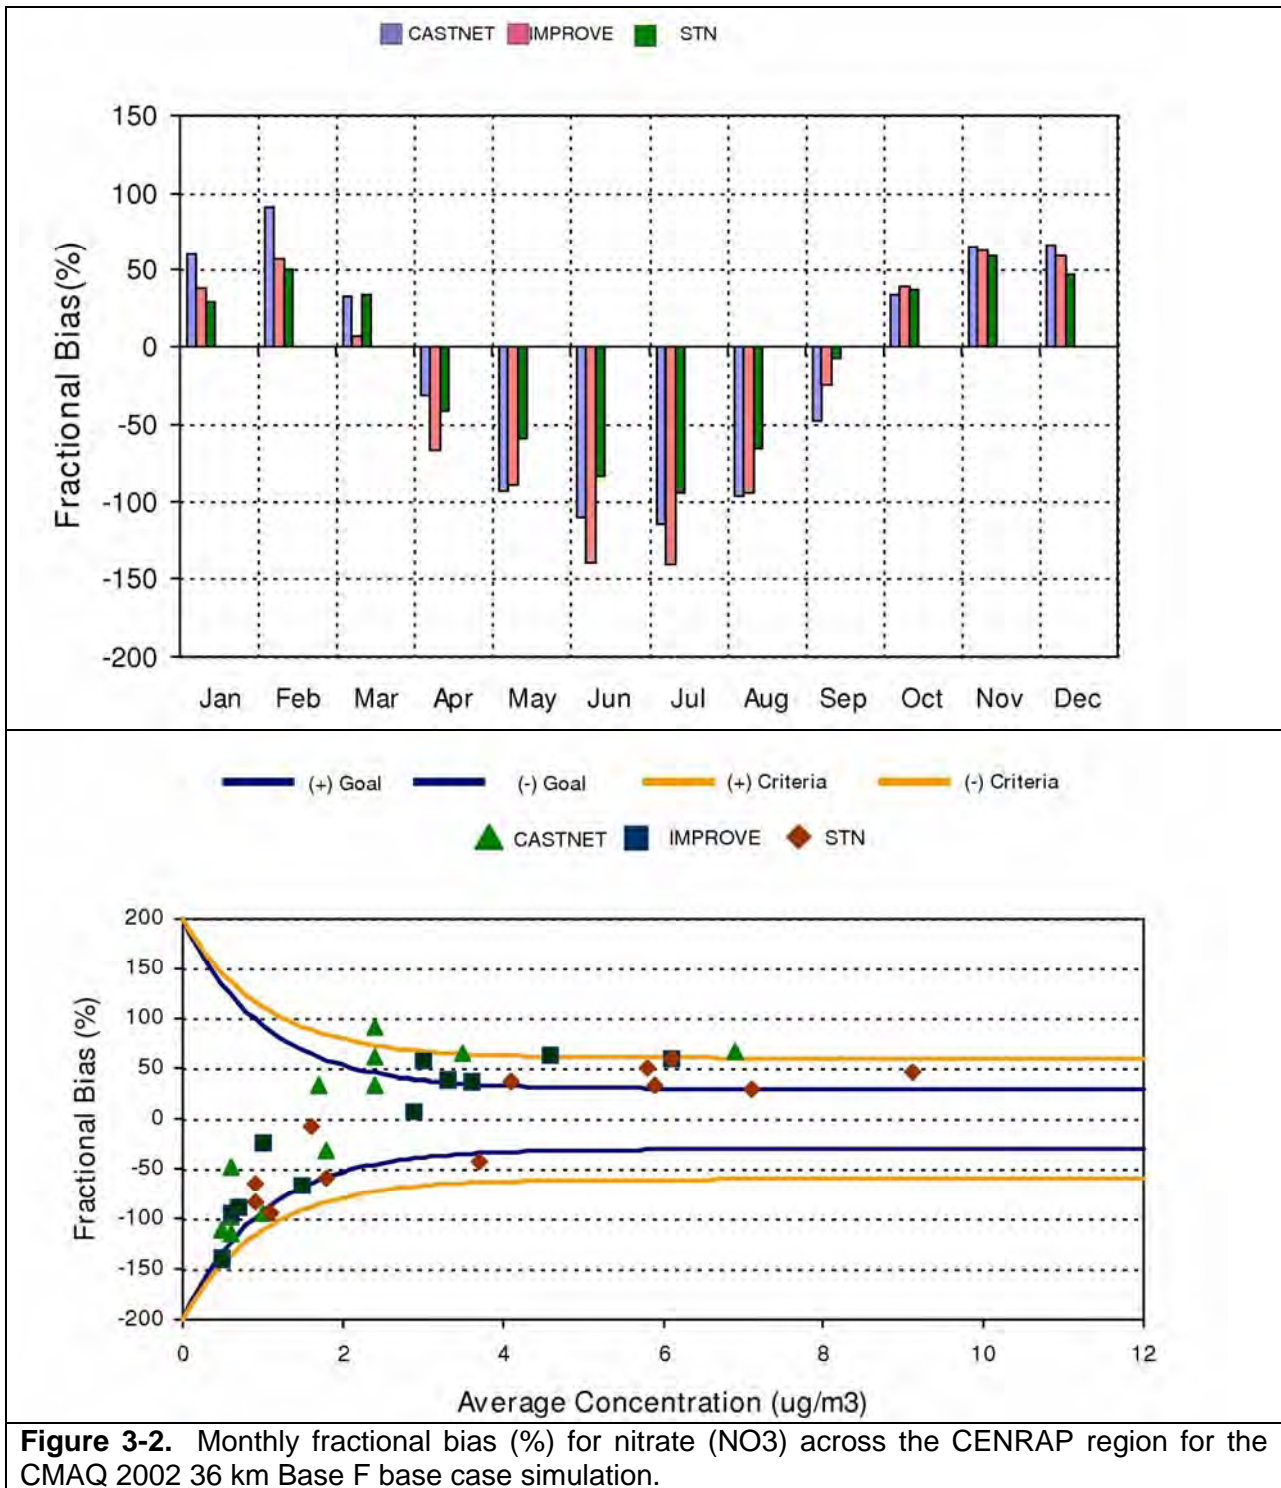

Monthly NO₃ model performance across the CENRAP region is characterized by a summer underestimation and winter overestimation bias (Figure 3-2). The summer underestimation bias is more severe, exceeding -100%. Whereas, the winter overestimation bias is approximately 50%. So based on statistics alone, it appears the summer underestimation bias is a bigger concern than the winter overestimation bias. However, the Bugle Plots in the bottom part of Figure 3-2 show that the summer underestimation bias occurs when NO₃ is very low and is not an important component of PM and visibility impairment. These summer values occur in the flared horn part of the Bugle Plot and the summer NO₃ performance, in most cases, achieves the model performance goal and always achieves the performance criteria. Whereas, the winter overstated NO₃ performance for the most part doesn't meet the performance goal and there are some months/networks that also don't meet the performance criteria.

3.5.3 Organic Matter Carbon (OMC) Model Performance

The OMC monthly fractional bias across IMPROVE and STN sites in the CENRAP region are shown in Figure 3-3. The fractional bias for OMC at the IMPROVE sites is quite good throughout the year with values generally within $\pm 20\%$, albeit with a slight winter overestimation and summer underestimation bias. At the urban STN sites, the model exhibits an underestimation bias throughout the year that ranges from -20% to -50%. The urban underestimation of OMC is a fairly common occurrence and suggests there may be missing sources of organic aerosol emissions in the modeling inventory.

The good performance of the model for OMC at the IMPROVE sites is also reflected in the Bugle Plot (Figure 3-3, bottom) with the bias achieving the proposed PM model performance goal for all months of the year. At the STN sites, however, the OMC bias falls between the proposed PM model performance goal and criteria, with error right at the goal for most months.

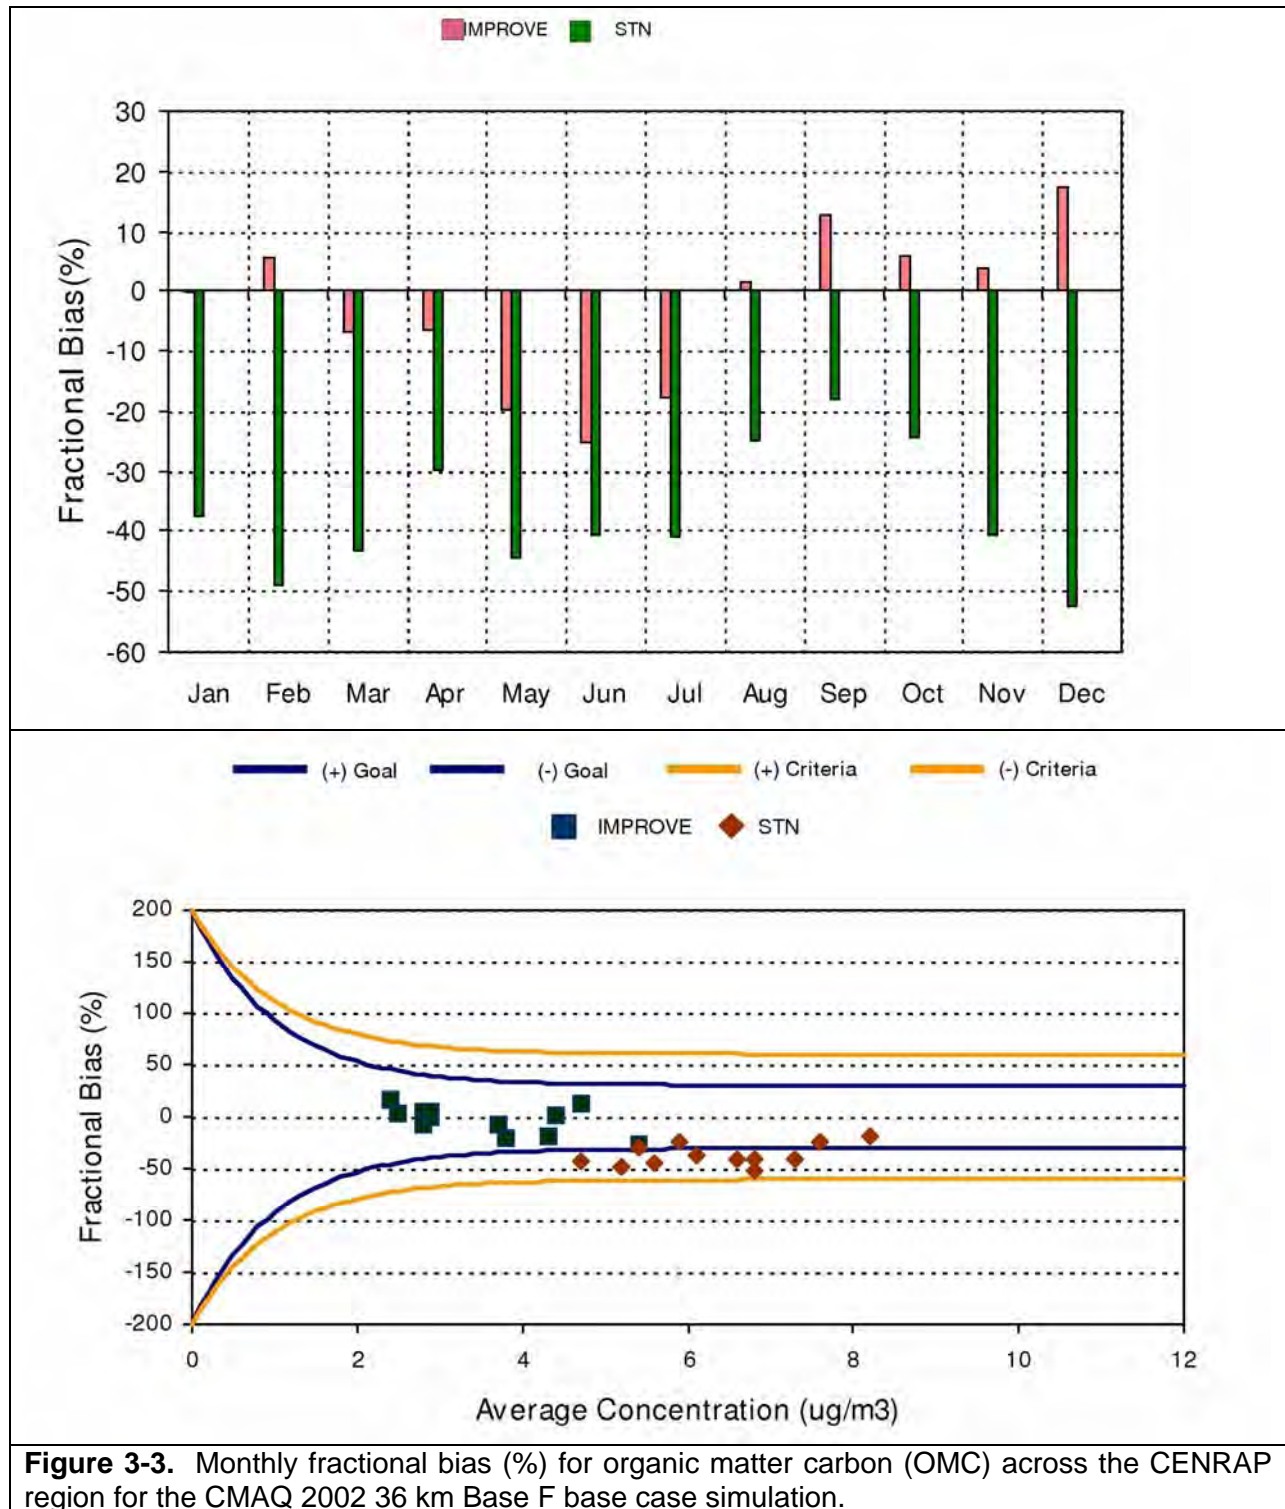

Figure 3-3. Monthly fractional bias (%) for organic matter carbon (OMC) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

3.5.4 Elemental Carbon (EC) Model Performance

The monthly average bias for EC across the IMPROVE and STN monitors in the CENRAP region are shown in Figure 3-4. The STN network exhibits small fractional bias year round, whereas the IMPROVE monitoring network exhibits a large underprediction bias in the summer months (-40% to -70%) and much smaller bias in the winter. The Bugle Plot puts the EC performance in context. The low EC concentrations at the IMPROVE sites results in bias values in the horn of the Bugle Plot. Thus, EC bias achieves the proposed PM performance goal for all months of the year.

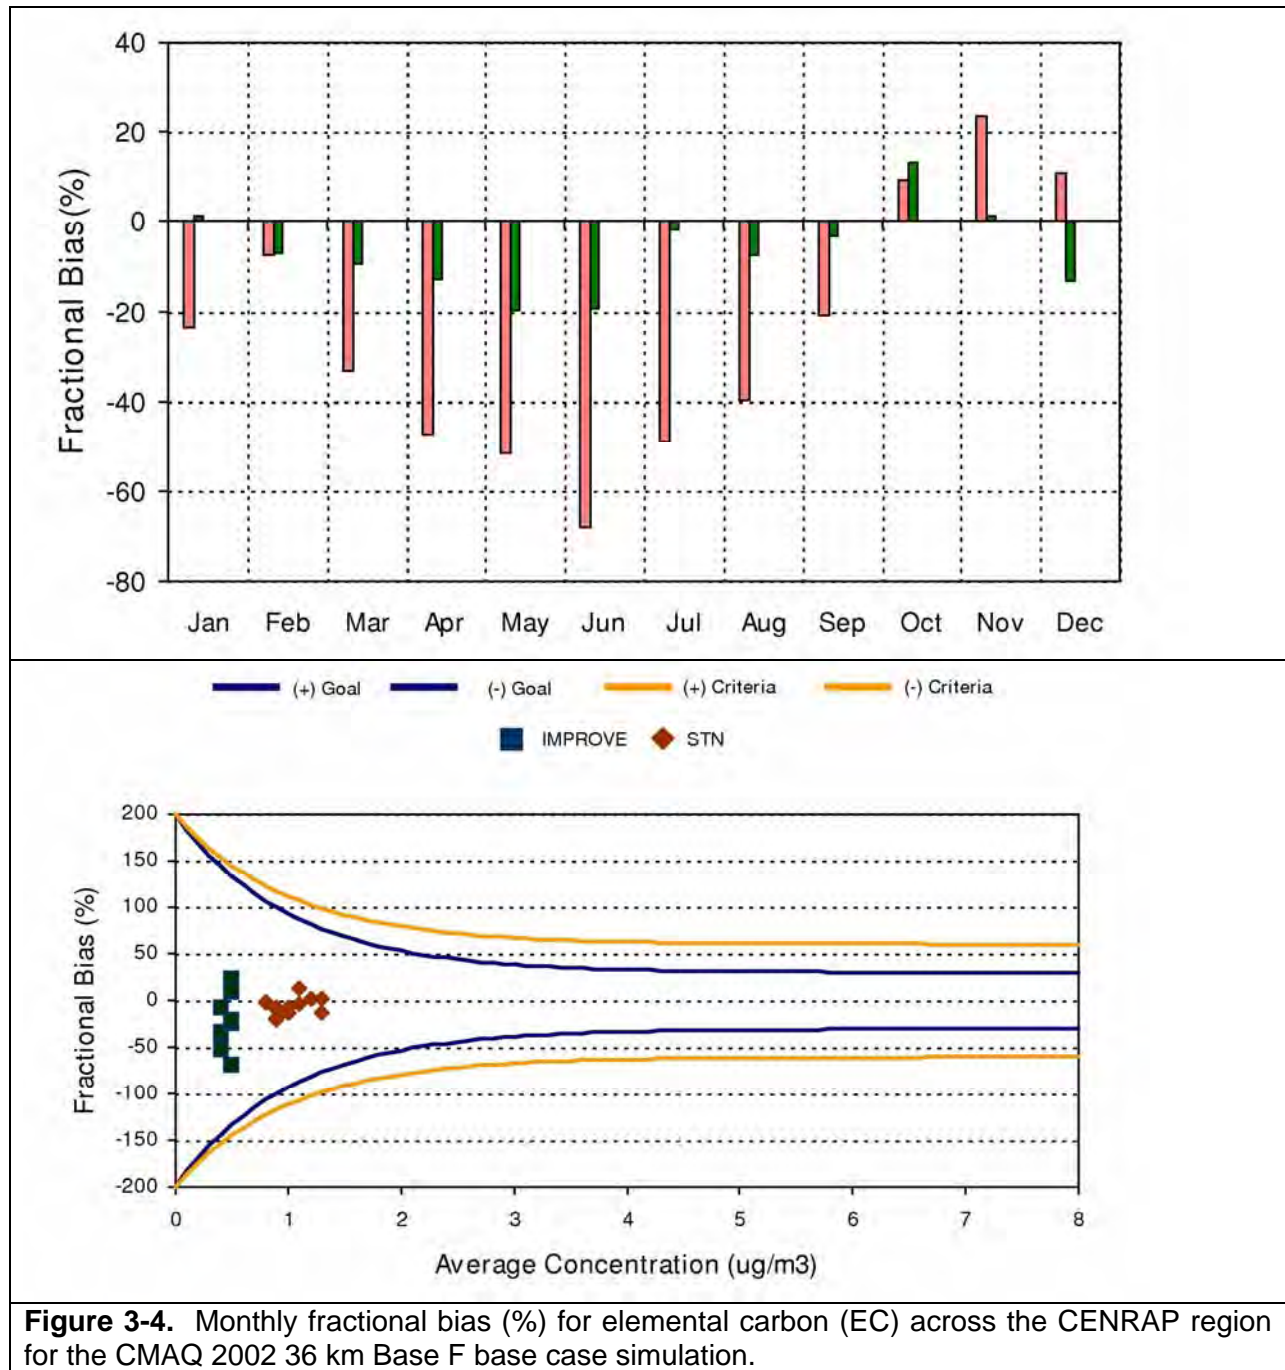

3.5.5 Other PM_{2.5} (Soil) Model Performance

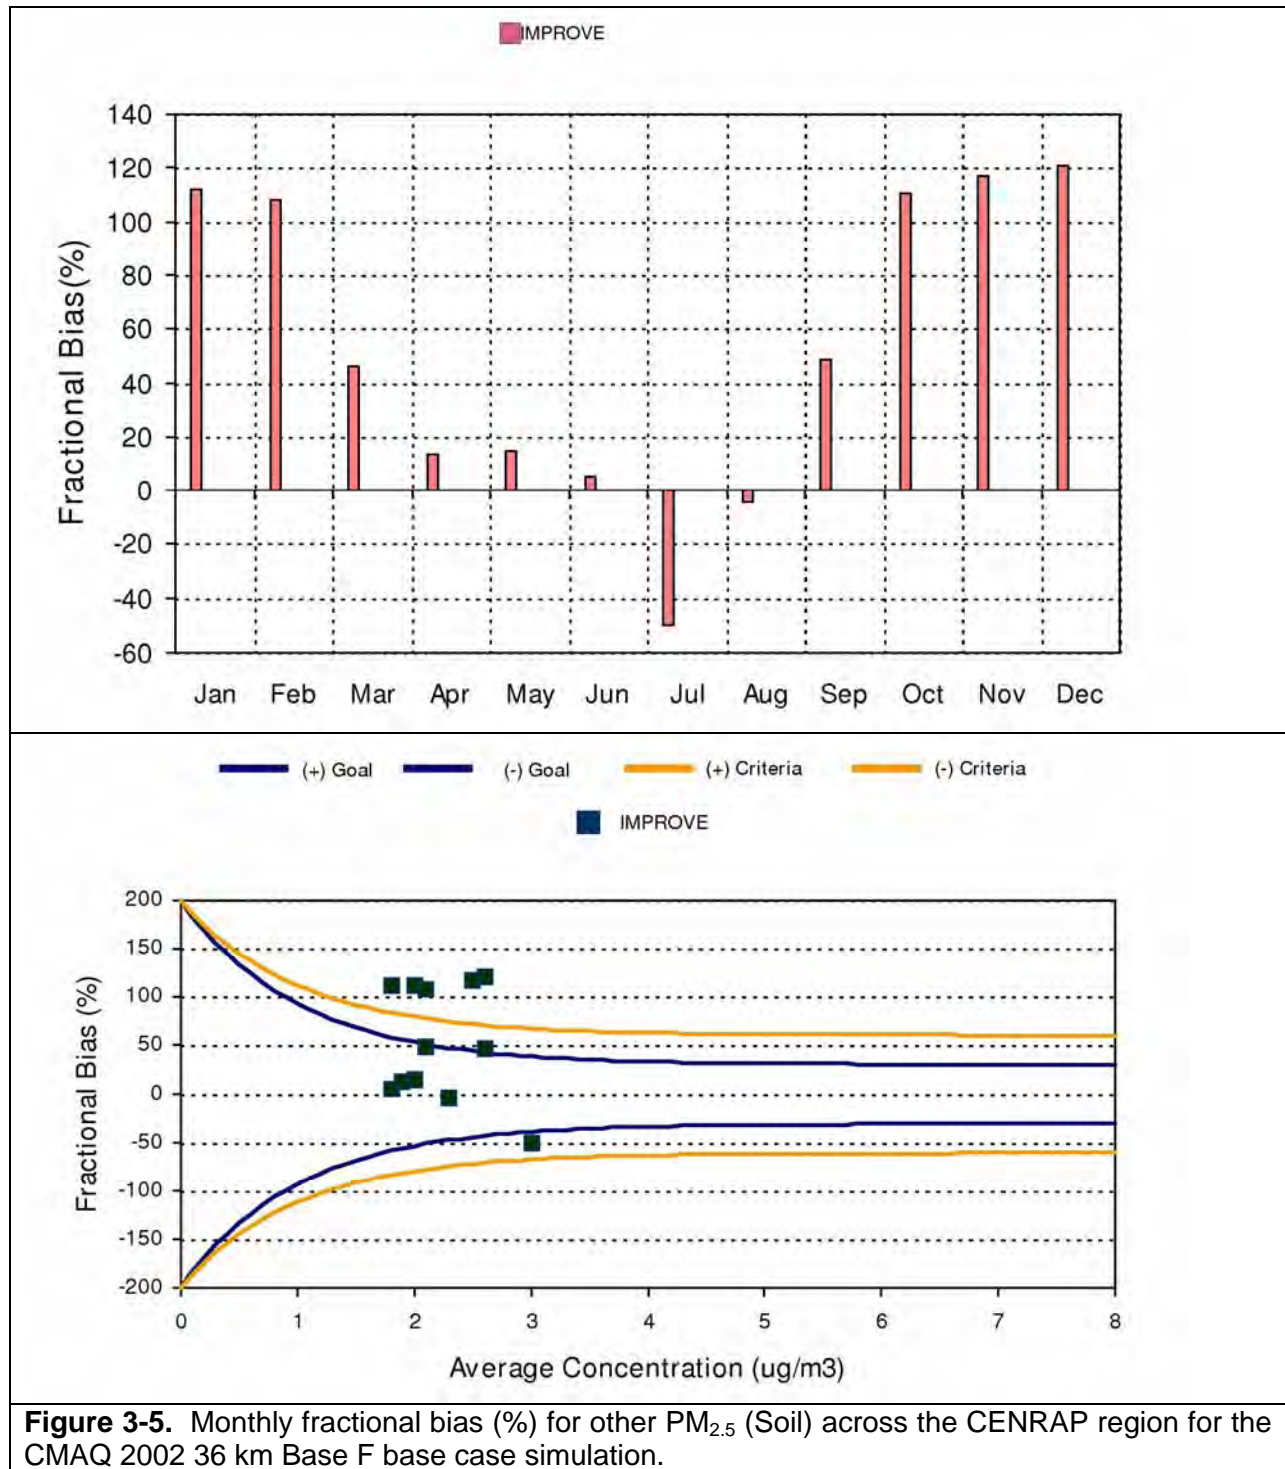

Figure 3-5 displays the monthly variation in the Soil fractional bias using IMPROVE measurements in the CENRAP region. During the winter months, the model exhibits a very large (> 100%) overestimation bias. With the exception of July, the summer monthly bias is toward a slight overprediction but generally less than 20%. The July underestimation bias appears to be driven by impacts of high Soil values from wind blown dust events (e.g., see July 2002 discussion in Appendix C). The Bugle Plot indicates that the summer Soil performance achieves the PM performance goal, a few months in the Spring/Fall period fall between the performance goal and criteria and the winter Soil performance exceeds the model performance criteria. Thus, the Soil performance is a cause for concern.

3.5.6 Coarse Mass (CM) Model Performance

The monthly average fractional bias values for CM are shown in Figure 3-6. In the winter the underprediction bias is typically in the -60% to -80% range. In the late Spring and Summer the underprediction bias ranges from -120% to -160%. As this underprediction bias is nearly systematic (i.e., an underprediction almost always occurs), then the fractional errors are the same magnitude as the bias.

The Bugle Plots clearly show that the CM model performance is a problem. The monthly bias exceeds both the performance goal and criteria for almost every month of the year.

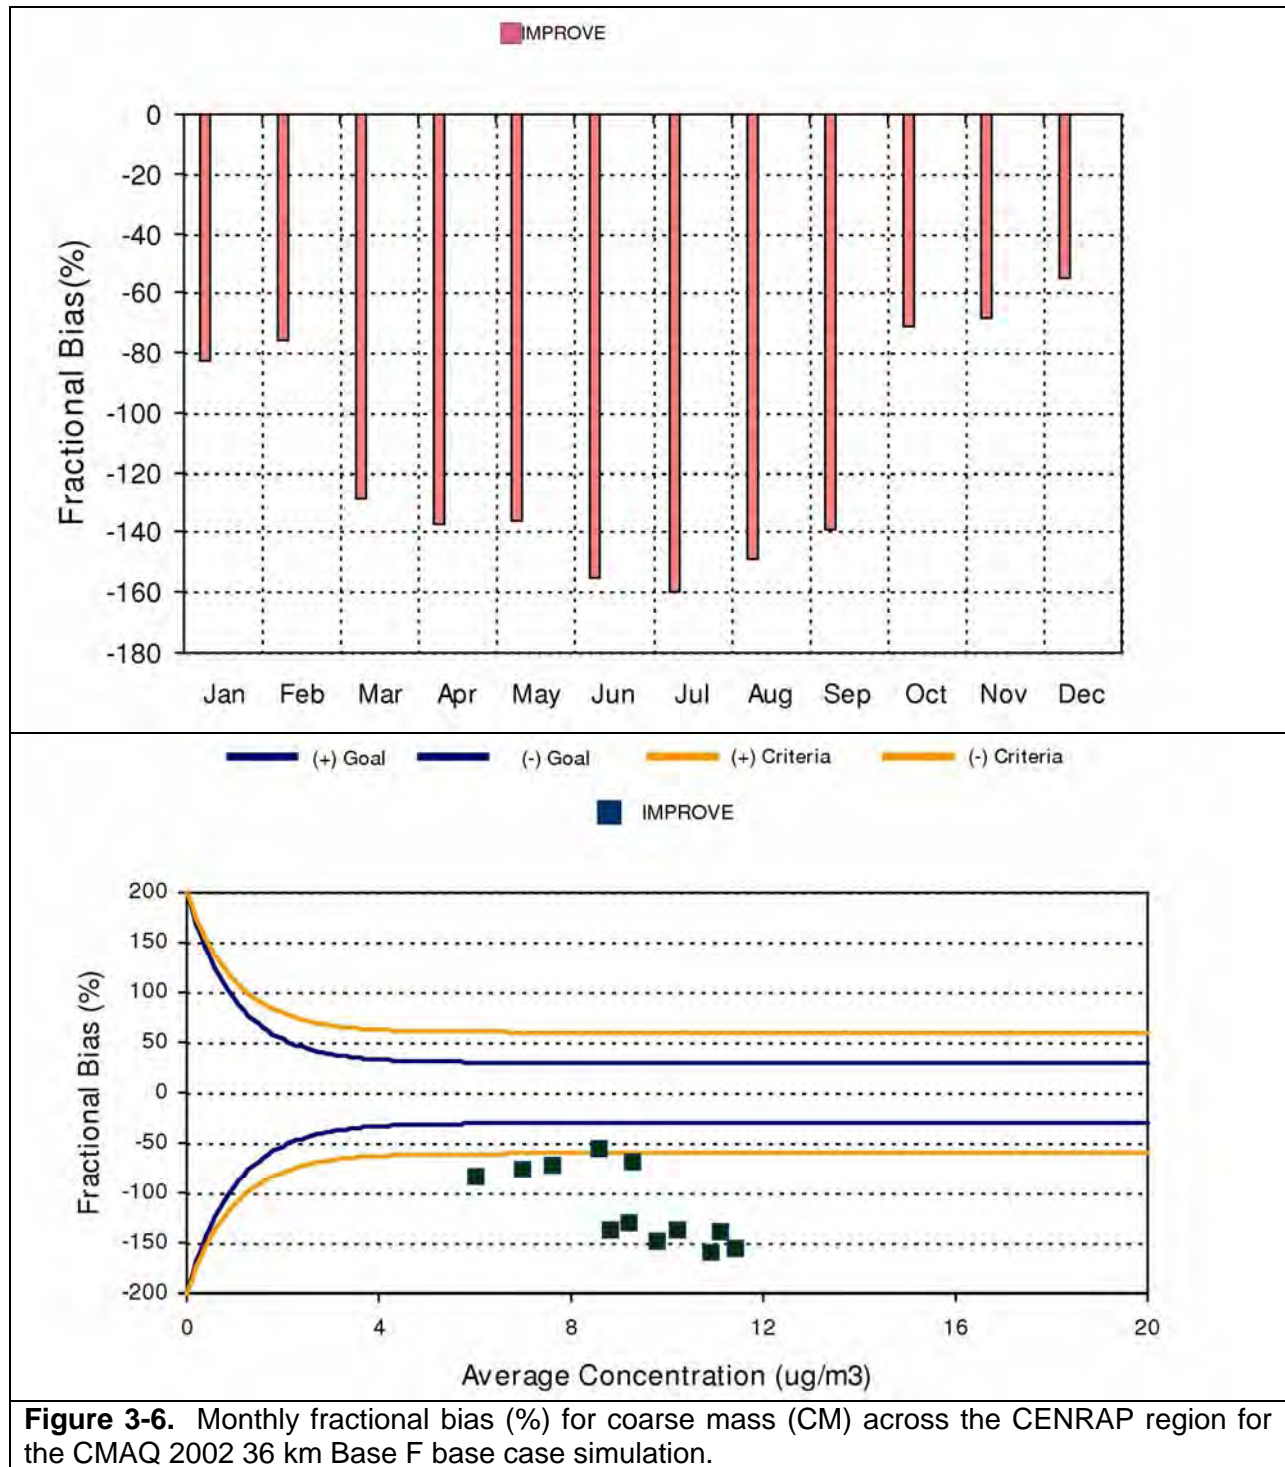

Figure 3-6. Monthly fractional bias (%) for coarse mass (CM) across the CENRAP region for the CMAQ 2002 36 km Base F base case simulation.

3.6 Diagnostic Model Performance Evaluation

The CASTNet and AQS networks also measure gas-phase species that are PM precursor or related species. The diagnostic evaluation of the 2002 36 km Base F CMAQ base case simulation for these compounds and the four seasonal months are presented in Appendix C. The displays for January are provided below as an example; the reader is referred to Appendix C for the rest of the monthly displays.

The CASTNet network measures weekly average samples of SO₂, SO₄, NO₂, HNO₃, NO₃ and NH₄. The AQS network collects hourly measurements of SO₂, NO₂, O₃ and CO. A comparison of the SO₂ and SO₄ performance provides insight into whether the SO₄ formation rate may be too slow or fast. For example, if SO₄ is underestimated and SO₂ is overestimated that may indicate chemical conversion rates that are too slow. Analyzing the performance for SO₄, HNO₃, NO₃, Total NO₃ and NH₄ provides insight into the equilibrium of these species. For example, if Total NO₃ performs well but HNO₃ and NO₃ do not, then there may be issues associated with the partitioning between the gaseous and particulate phases of nitrate. Causes for incorrect HNO₃/NO₃ partitioning could include inadequate ammonia emissions and/or poorly characterized meteorological conditions (e.g., temperature).

3.6.1 Diagnostic Model Performance in January 2002

In January, SO₂ is overstated across both the CASTNet and AQS sites with fractional bias values of 38% (Figure 3-7) and 31% (Figure 3-8), respectively. SO₄ is understated by -34% across the CASTNet monitors (Figure 3-7) and -12% and -13% for the IMPROVE and STN networks (Figure C-4a). Wet SO₄ deposition is also overstated in January (+40%, Figure C-4a). Given that SO₂ emissions are well characterized, these results suggest that the January SO₄ underestimation may be partly due to understated transformation rates of SO₂ to SO₄ and overstated wet SO₄ deposition.

Total NO₃ is overestimated by 35% on average across the CASTNet sites in the CENRAP region in January (Figure 3-7). HNO₃ is underestimated (-34%) and particle NO₃ is overestimated (+61%) suggesting there are gas/particle equilibrium issues. An analysis of the time series of the four CASTNet stations reveals that NO₃, HNO₃ and NH₄ performance is actually very reasonable at the west Texas site and the HNO₃ underestimation and NO₃ overestimation bias is coming from the east Kansas, central Arkansas and northern Minnesota CASTNet sites (see Figure C-3 for site locations). One potential contributor for this performance problem could be overstated NH₃ emissions. However, the Total NO₃ overestimation bias suggests that the model estimated NO_x oxidation rate may be too high in January.

The SO₂, NO₂, O₃ and CO performance across the AQS sites in January is shown in Figure 3-8. The AQS monitoring network is primarily an urban-oriented network. So, it is not surprising that the model is underestimating concentrations of primary emissions when a 36 km grid is used. NO₂ is underestimated by approximately 5%, and CO by approximately 67%. Ozone is also underestimated on average, especially the maximum values above 60 ppb.

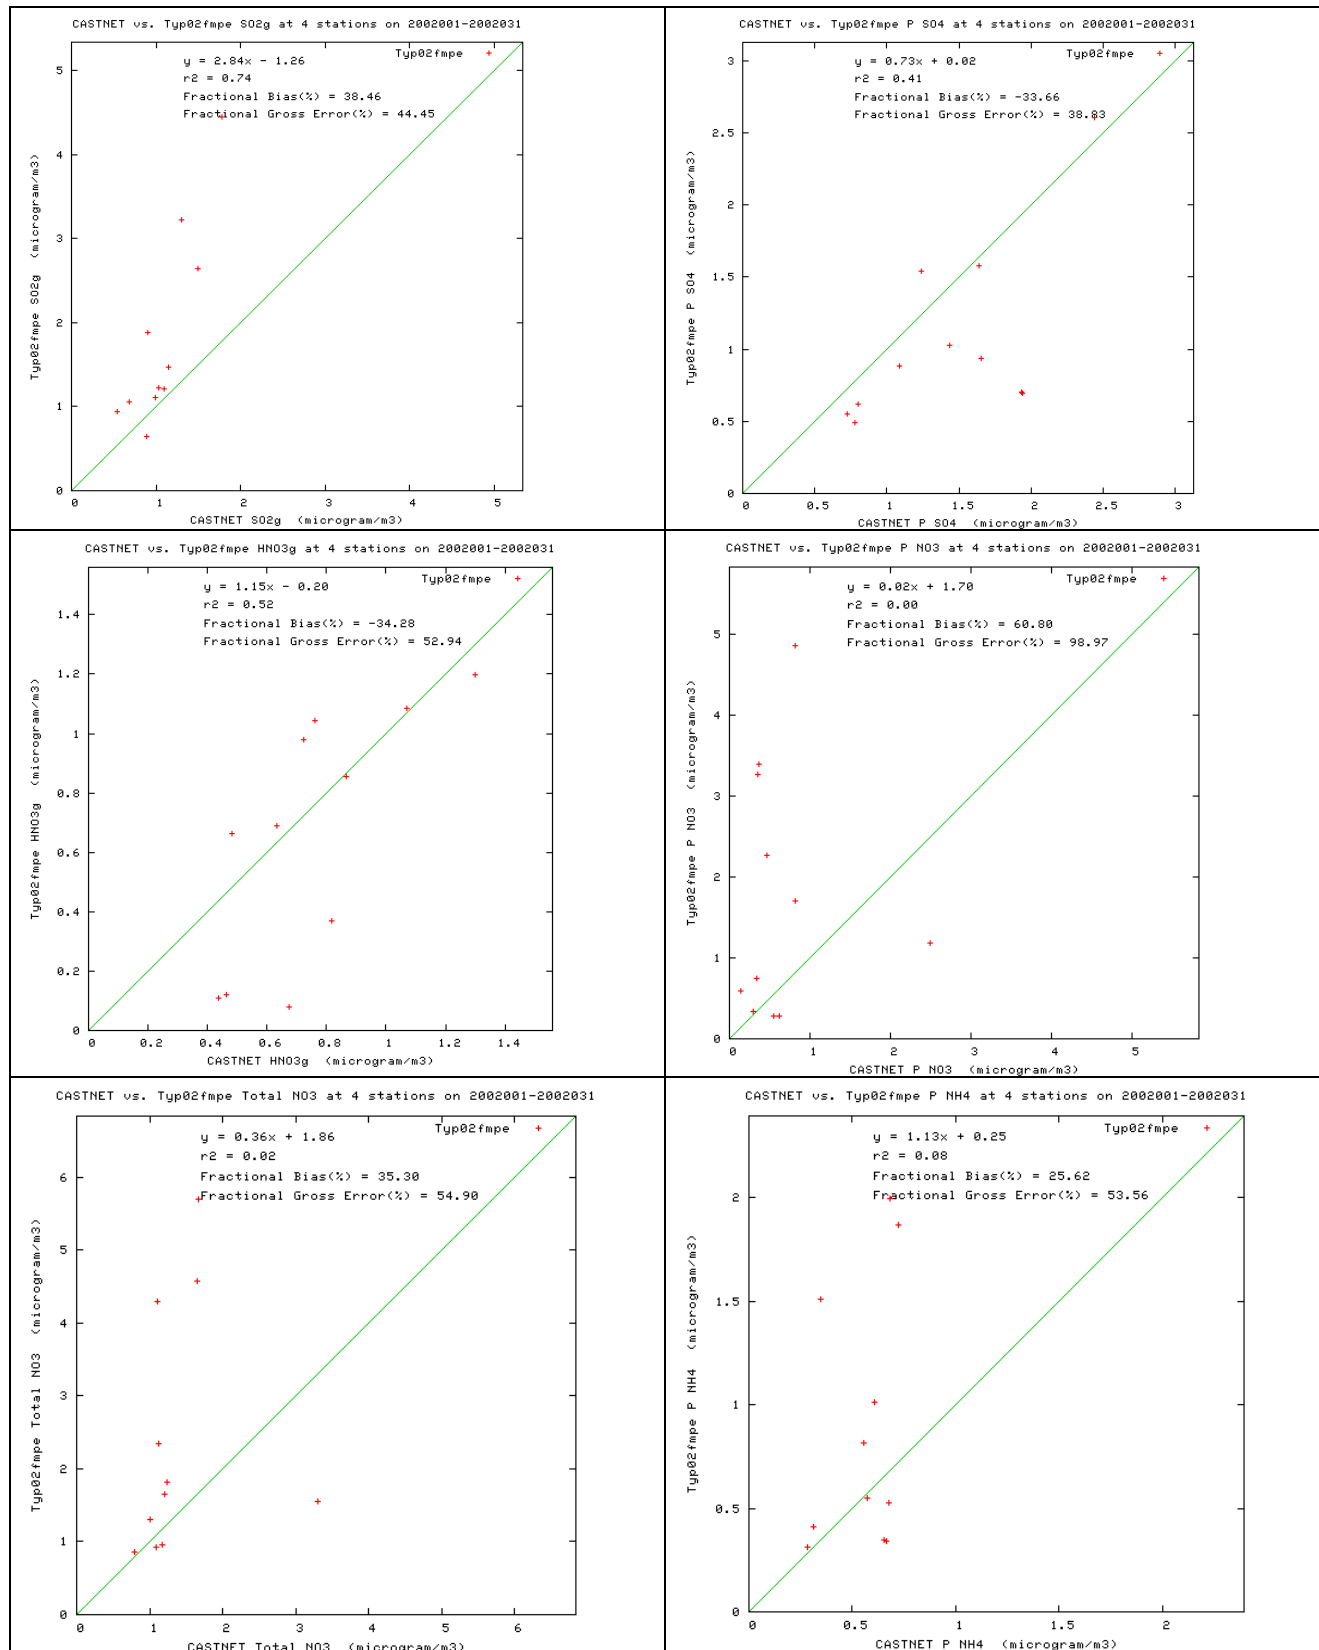

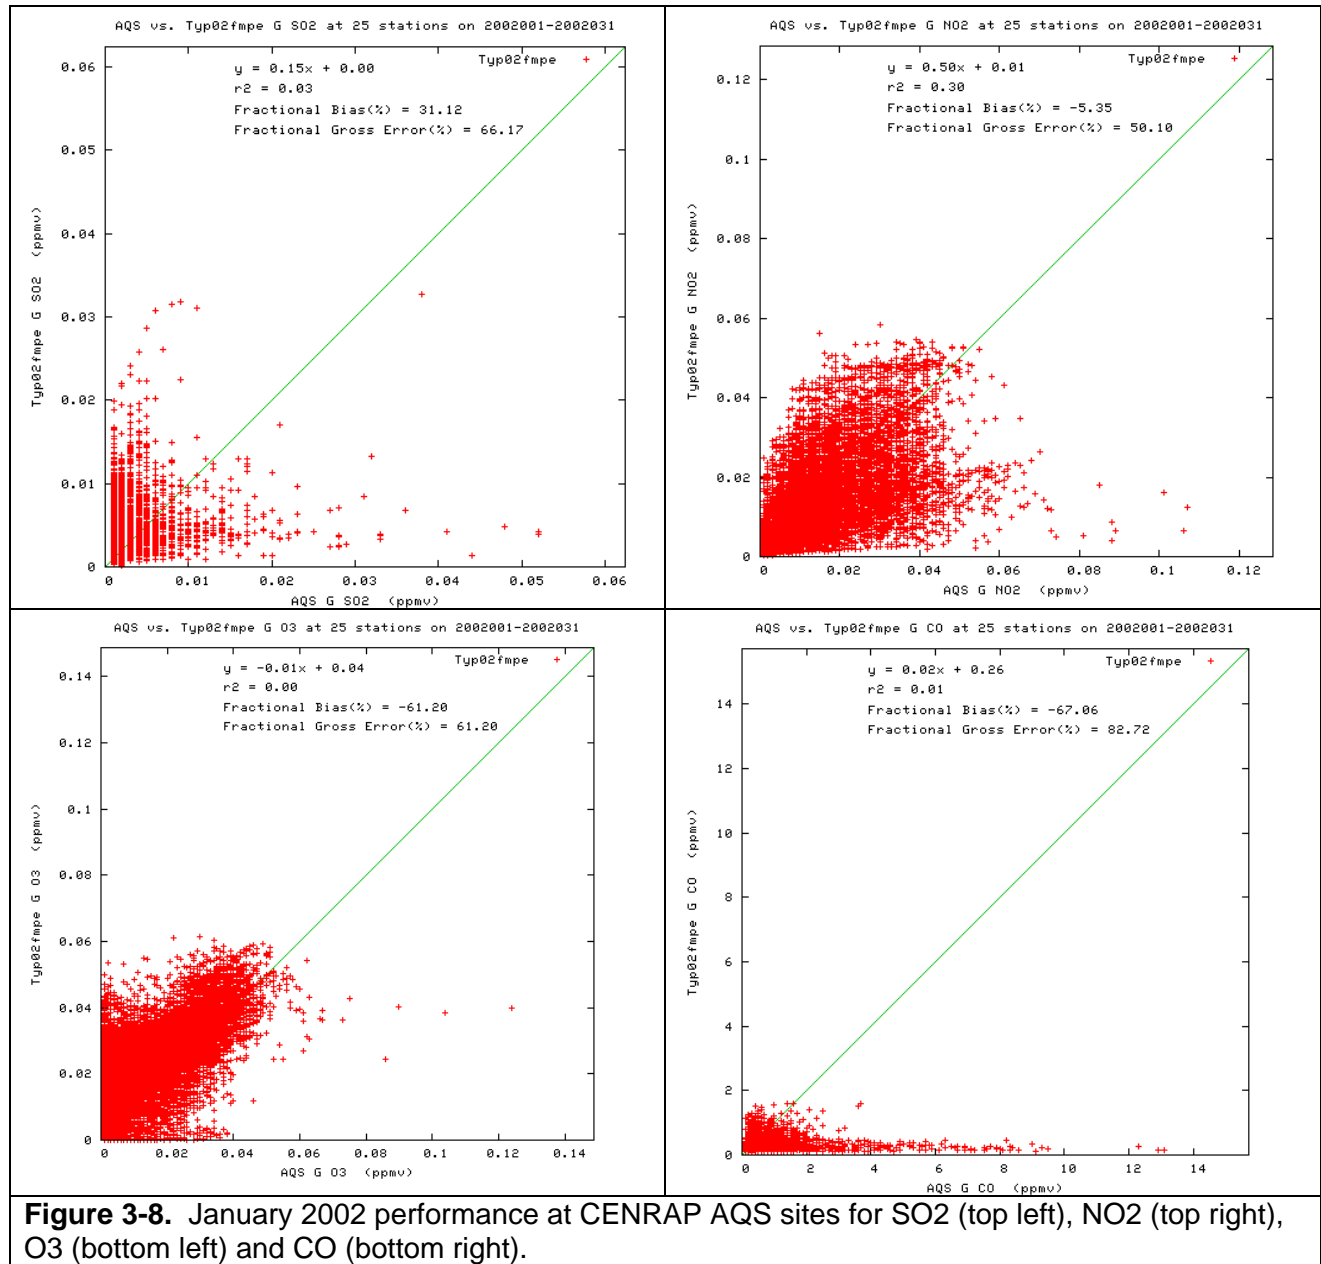

Figure 3-7. January 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

3.6.2 Diagnostic Model Performance In April

In April there is an average SO₂ overestimation bias across the CASTNet (+15%) and underestimation bias across the AQS (-10%) networks (Figures C-42 and C-43). SO₄ is underestimated across all networks by -30% to -58% (Figure C-5a). The wet SO₄ deposition bias is near zero. Both SO₂ and SO₄ are underestimated at the west Texas CASTNet monitor in April suggesting SO₂ emissions in Mexico are likely understated.

The HNO₃ performance in April is interesting with almost perfect agreement except for 5 modeled-observed comparisons that drives the average underprediction bias of -29% (Figure C-42). On Julian Day 102 there is high HNO₃ at the MN, KS and OK CASTNet sites that is not captured by the model. Given that HNO₃, NO₃ and Total NO₃ are all underestimated by about the same amount (-30%), then part of the underestimation bias is likely due to too slow oxidation of NO_x.

There is a lot of scatter in the NO₂ and O₃ performance that is more or less centered on the 1:1 line of perfect agreement with bias values of -8% and -21%, respectively (Figure C-43). CO is underestimated by -72% with the model unable to predict CO concentrations above 1 ppm due to the use of the coarse 36 km grid spacing. Mobile sources produce a vast majority of the CO emissions. So, AQS monitors for CO compliance are located near roadways, which are not simulated well using a 36 km grid.

3.6.3 Diagnostic Model Performance In July

In July SO₂ is slightly underestimated across the CASTNet (-5%) and AQS (-12%) networks (Figures C-44 and C-45). SO₄ is more significantly underestimated across all networks (-22% to -53%, as shown in Figure C-6a). Since wet deposition SO₄ is also underestimated, it is unclear why all sulfur species are underestimated.

The nitrate species are also all underestimated with the Total NO₃ bias (-56%) being between the HNO₃ bias (-35%) and NO₃ bias (-115%). The modeled NO₃ values are all near zero with little correlation with the observations, whereas the observed HNO₃ and Total NO₃ is tracked well with correlation coefficients of 0.74 and 0.76. These results suggest that the July NO₃ model performance problem is partly due to insufficient formation of Total NO₃, but mainly due to incorrect partitioning of the Total NO₃.

Again, there is abundant scatter in the AQS NO₂ scatter plot for July (Figure C-45) resulting in a low bias (0%) but high error (65%). Ozone performance also exhibits a low bias (-15%) and error (20%), but the model is incapable of simulating ozone above 100 ppb. Although CO performance in July is better than the previous months, it still has a large underestimation bias of 82%.

3.6.4 Diagnostic Model Performance In October

SO₂ is overstated in October across the CASTNet (+28%) and AQS (+33%) sites (Figures C-46 and C-47). Although SO₄ is understated across the CASTNet sites (-24%), the bias across the IMPROVE (-6%) and STN (0%) sites are near zero (Figure C-7a).

Performance for HNO₃ is fairly good with a low bias (+12%) and error (30%). But NO₃ is overstated (+34%) leading to an overstatement of Total NO₃ (+37%). The overstatement of NO₃ leads to an overstatement of NH₄ as well (Figure C-46)

As seen in the other months, NO₂ exhibits a lot of scatter resulting in a low correlation (0.22) and high error (61%) but low bias (12%). The model tends to underpredict the high and overpredict the low O₃ observations resulting in a -29% bias and low correlation coefficient. CO is also underpredicted (-76%) for the reasons discussed previously.

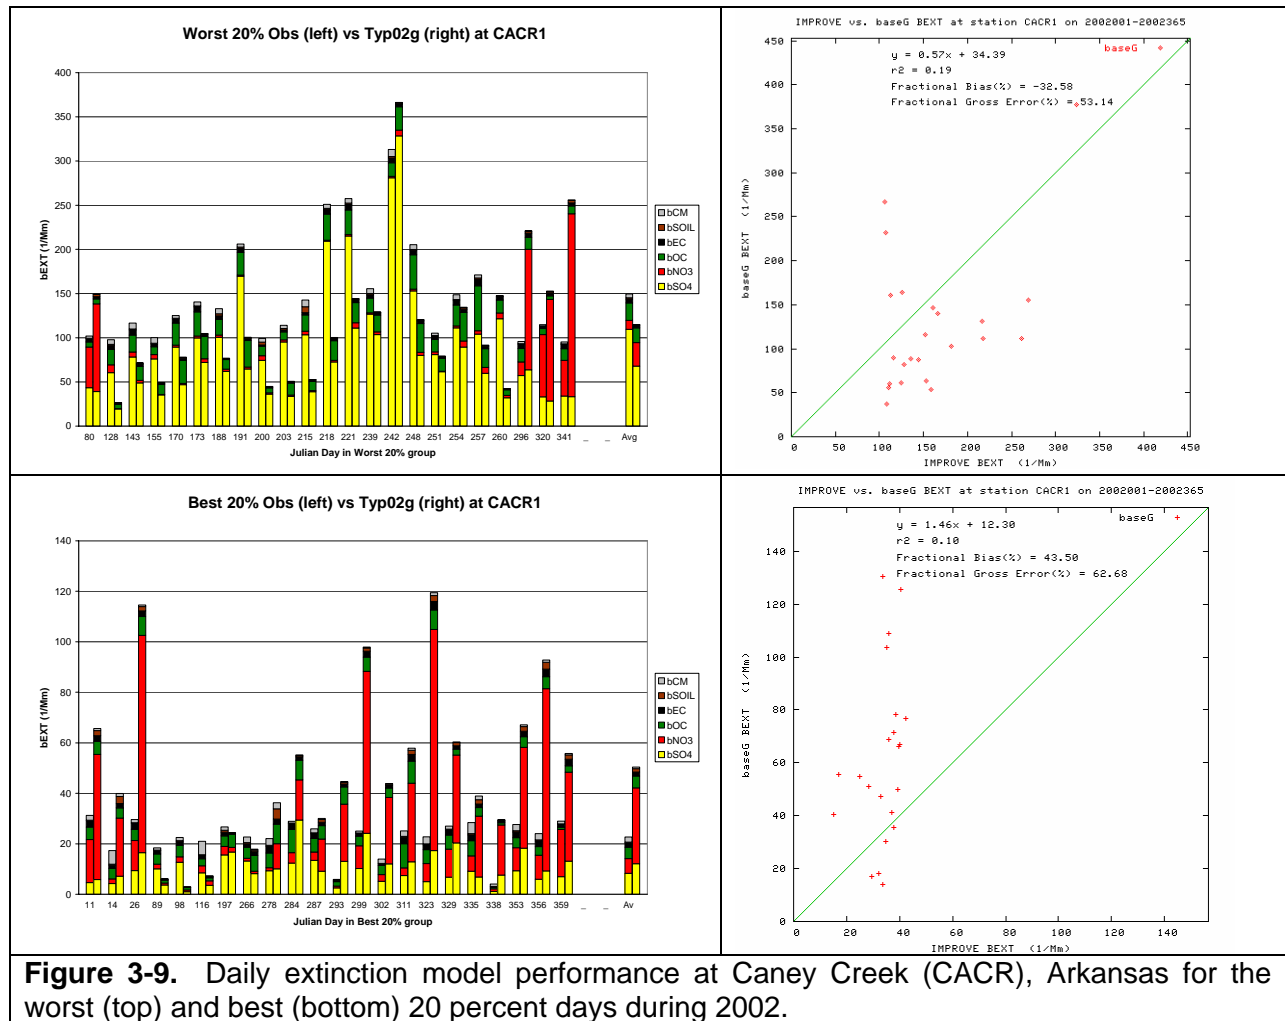

3.7 Performance at CENRAP Class I Areas for the Worst and Best 20 Percent Days

In this section, and in section C.5 of Appendix C, we present the results of the model performance evaluation at each of the CENRAP Class I areas for the worst and best 20 percent days. Performance on these days is critical since they are the days used in the 2018 visibility projections discussed in Chapter 4. For each Class I area we compared the predicted and observed extinction of the worst and best 20 percent days below. In Appendix C the PM species-specific extinction is also compared for the worst 20 percent days.

3.7.1 Caney Creek (CACR) Arkansas

The ability of the CMAQ model to estimate visibility extinction at the CACR Class I area on the 2002 worst and best 20 percent days is provide in Figures 3-9 and C-48. On most of the worst 20 percent days at CACR total extinction is dominated by SO₄ extinction with some extinction due to OMC. On four of the worst 20 percent days extinction is dominated by NO₃. The average extinction across the worst 20 percent days is underestimated by -33% (Figure 3-9), which is primarily due to a -51% underestimation of SO₄ extinction combined with a 6% overestimation of NO₃ extinction (Figure C-48). Performance for OMC extinction at CACR on the worst 20 percent days is pretty good with a -20% bias and 36% error. EC extinction is systematically underestimated. Soil extinction has low bias (-19%) but lots of scatter and high error (74%), while CM extinction is greatly underestimated (bias of -153%).

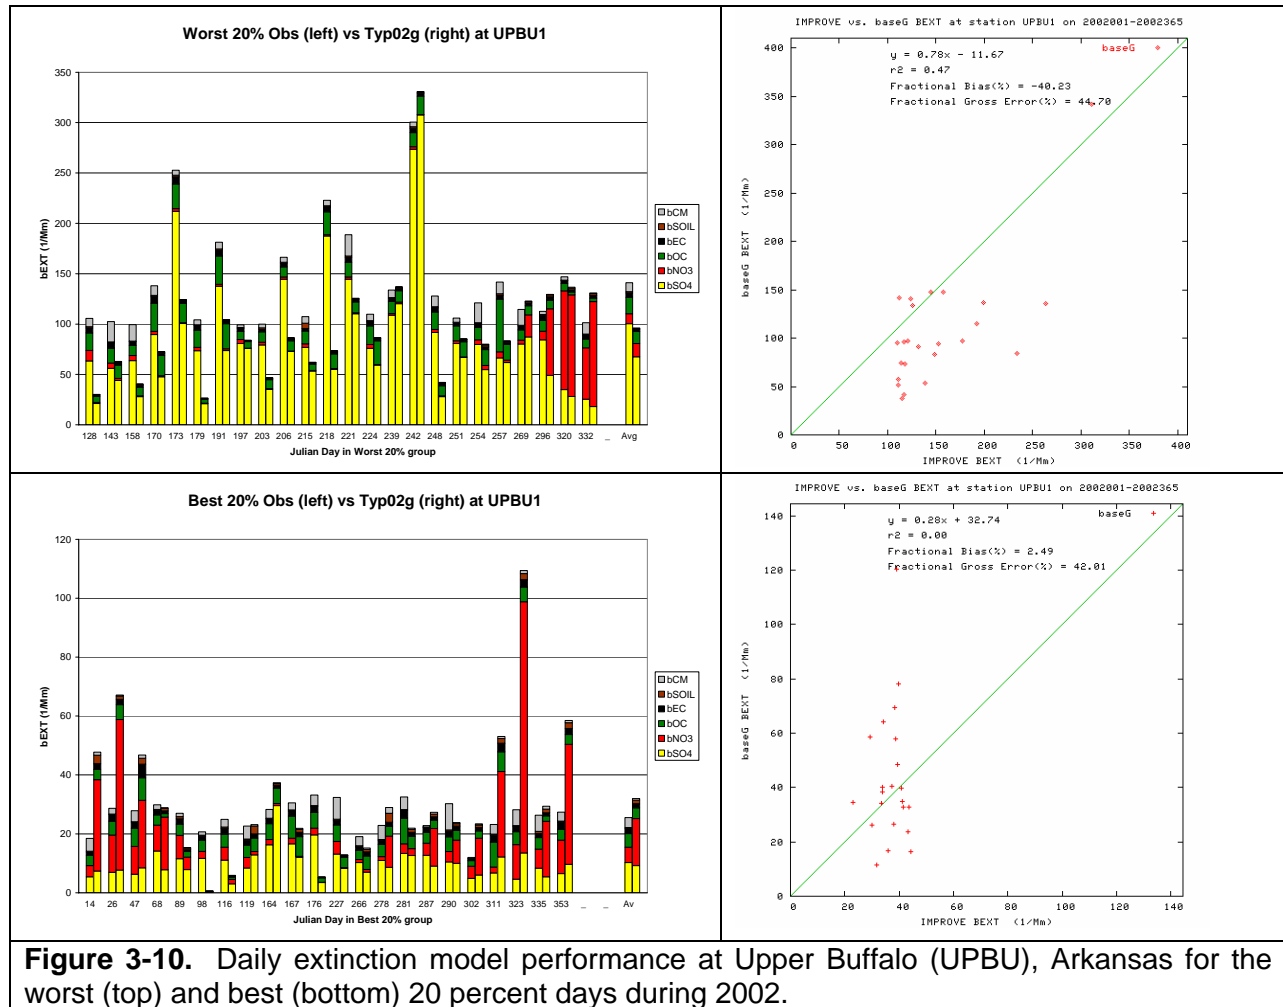

On the best 20 percent days at CACR the observed extinction ranges from 20 to 40 Mm⁻¹. Whereas, the modeled extinction has a much larger range from 15 to 120 Mm⁻¹. Much of the modeled overestimation of total extinction on the best 20% days (+44% bias) is due to NO₃ overestimation (+94% bias).

3.7.2 Upper Buffalo (UPBU) Arkansas

Model performance at the UPBU Class I area for the worst and best 20 percent days is shown in Figures 3-10 and C-49. On most of the worst 20 percent days at UPBU, visibility impairment is dominated by SO₄, although there are also two high NO₃ days. The model underestimates the average of the total extinction on the worst 20 percent days at UPBU by -40% (Figure 3-10), which is due to an underestimation of extinction due to SO₄, OMC and CM by -46%, -33% and -179%, respectively.

On the best 20 percent days at UPBU, the model performs reasonably well with a low bias (2%) and error (42%). But again, the model has a much wider range in extinction values across the best 20 percent days (15 to 120 Mm⁻¹) than observed (20 to 45 Mm⁻¹). There are five days in which the modeled NO₃ overprediction is quite severe and when those days are removed the range in the modeled and observed extinction on the best 20 percent days is quite similar to the observed, although the model gets much cleaner on the very cleanest modeled days.

3.7.3 Breton Island (BRET), Louisiana

The observed total extinction on the worst 20 percent days at Breton Island is underestimated by -71% (Figure 3-11), which is due to an underestimation of each component of extinction (Figure C-50) by from -50% to -70% (SO₄, OMC and Soil) to over -100% (EC and CM). The observed extinction on the worst 20 percent days ranges from 90 to 170 Mm⁻¹, whereas the modeled values drop down to as low as approximately 15 Mm⁻¹. On the best 20 percent days the range of the observed and modeled extinction is similar (roughly 10 to 50 Mm⁻¹) that results in a reasonably low bias (-22%), but there is little agreement on which days are higher or lower resulting in a lot of scatter and high error (54%).

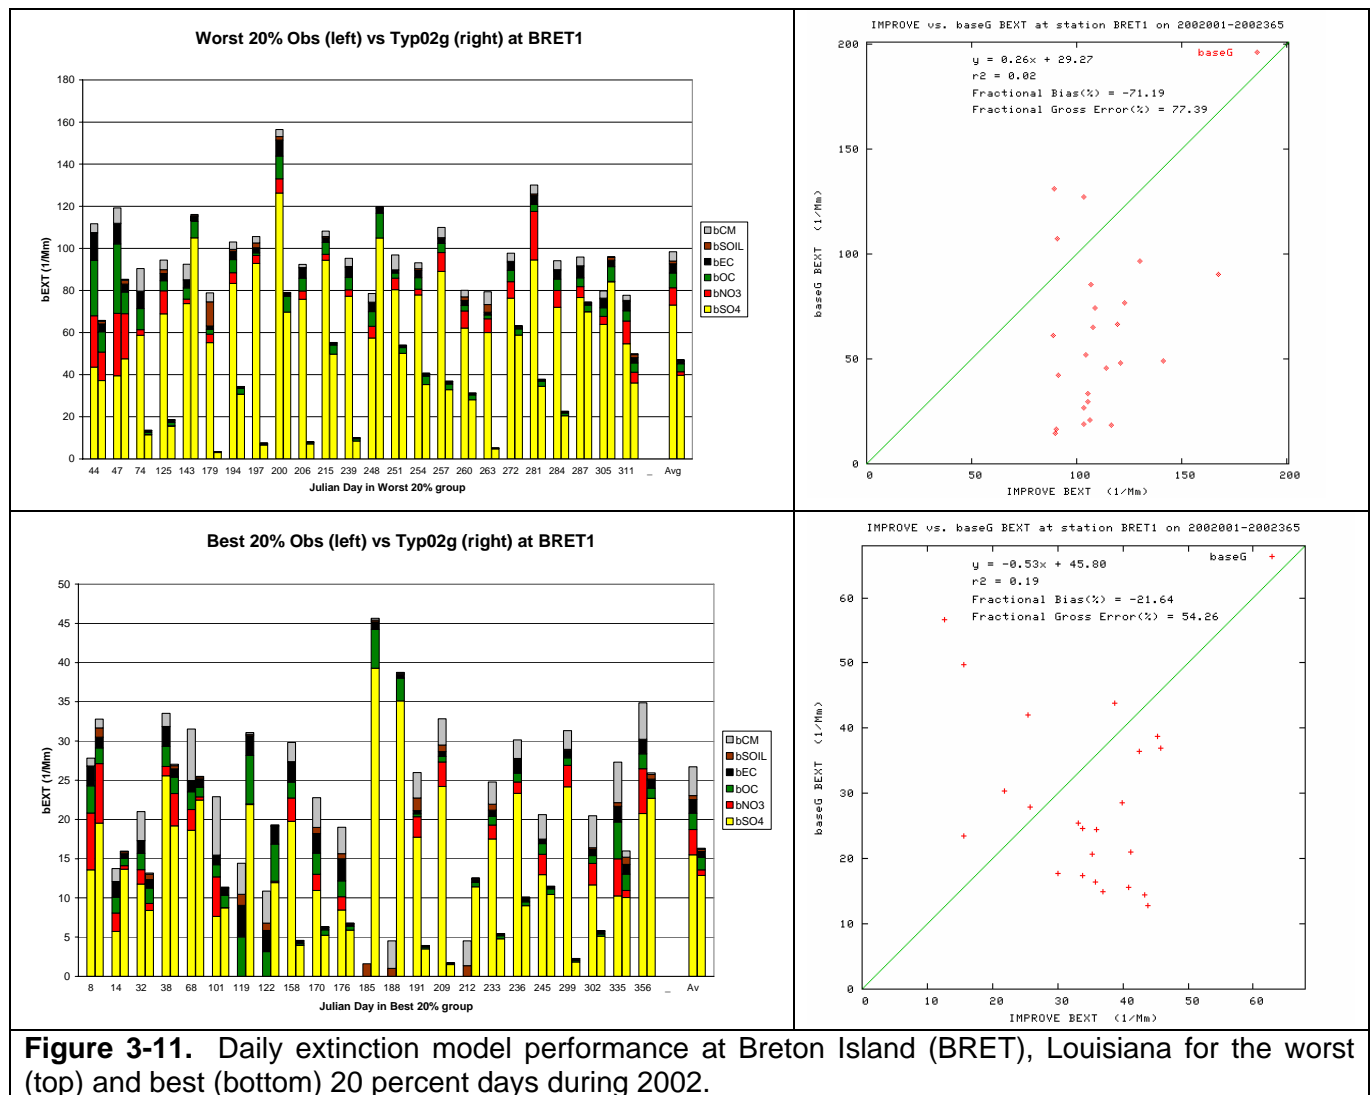

Figure 3-11. Daily extinction model performance at Breton Island (BRET), Louisiana for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.4 Boundary Waters (BOWA), Minnesota

There are three types of days during the worst 20 percent days at BOWA: SO4 days, OMC days and NO3 days (Figure 3-12). The two high OMC days are likely fire impact events that the model captures to some extent on one day and not on the other. On the five high (> 20 Mm⁻¹) NO3 extinction days the model predicts the observed extinction well on three days and overestimates by a factor of 3-4 on the other two high NO3 days. SO4 is underestimated by -43% on average across the worst 20 percent days at BOWA.

With the exception of two days, the model reproduces the total extinction for the best 20 percent days at BOWA quite well with a bias and error value of +14% and 22% (Figure 3-12). Without these two days, the modeled and observed extinction both range between 15 and 25 Mm⁻¹.

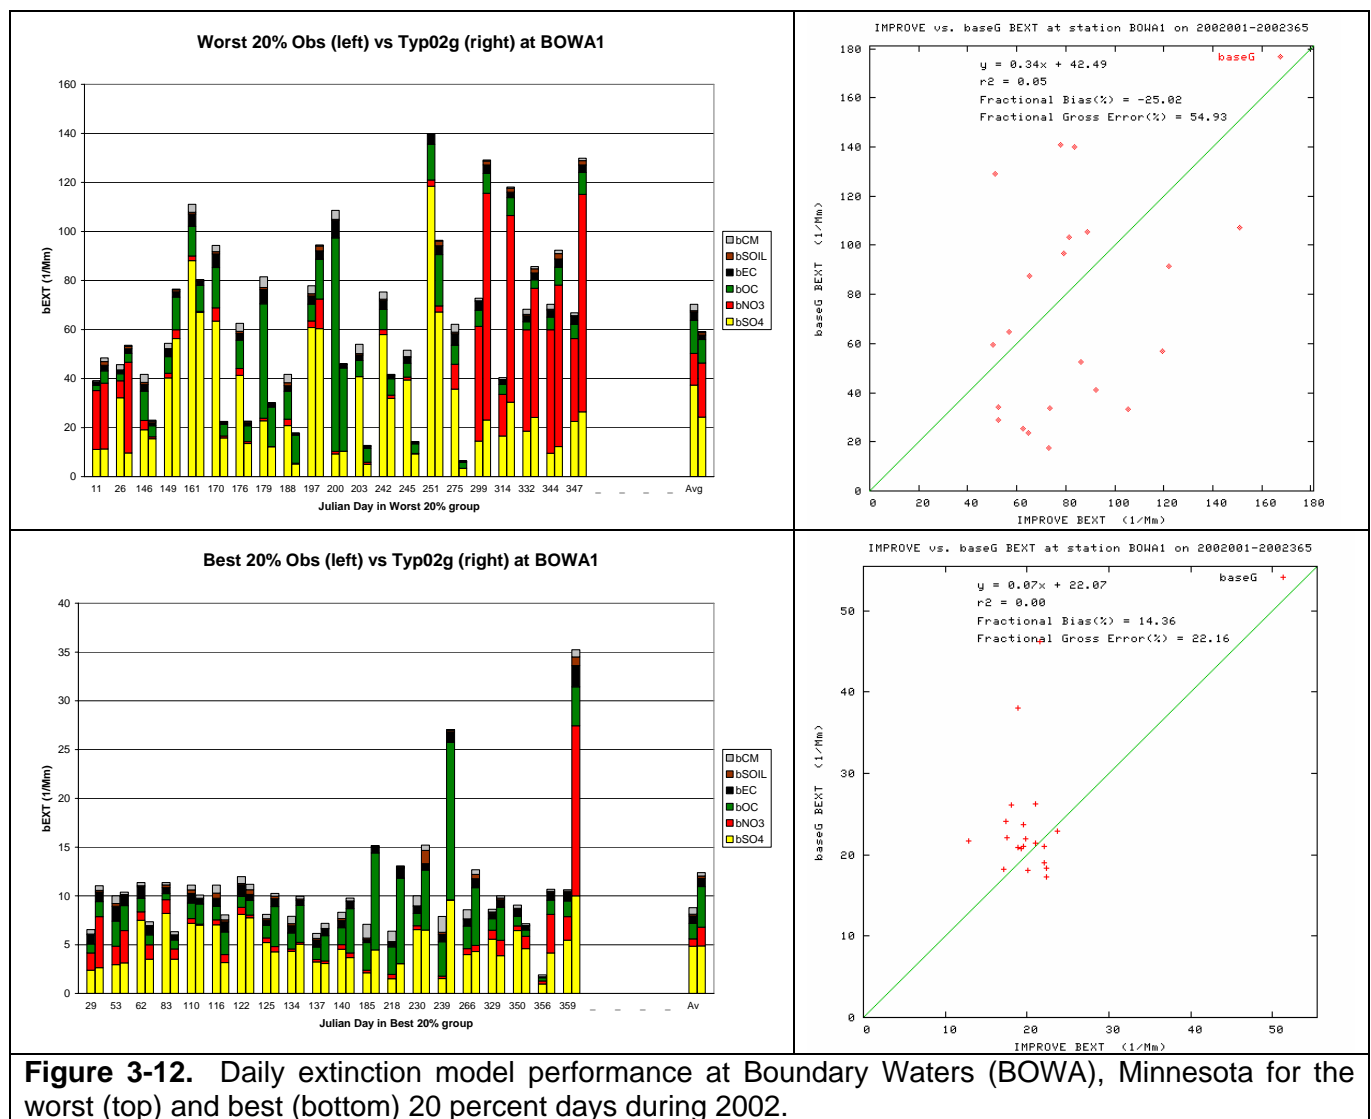

Figure 3-12. Daily extinction model performance at Boundary Waters (BOWA), Minnesota for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.5 Voyageurs (VOYA) Minnesota

VOYA is also characterized by SO₄, NO₃ and OMC days (Figure 3-13). Julian Days 179 and 200 are high OMC days that were also high OMC days at BOWA again indicating impacts from fires in the area that is not fully captured by the model. SO₄ and NO₃ performance is fairly good and, without the fire days, OMC performance looks good as well (Figure C-52). On the best 20 percent days there is one day the modeled extinction is much higher than observed and a few others that are somewhat higher, but for most of the best 20 percent days the modeled extinction is comparable to the observed values.

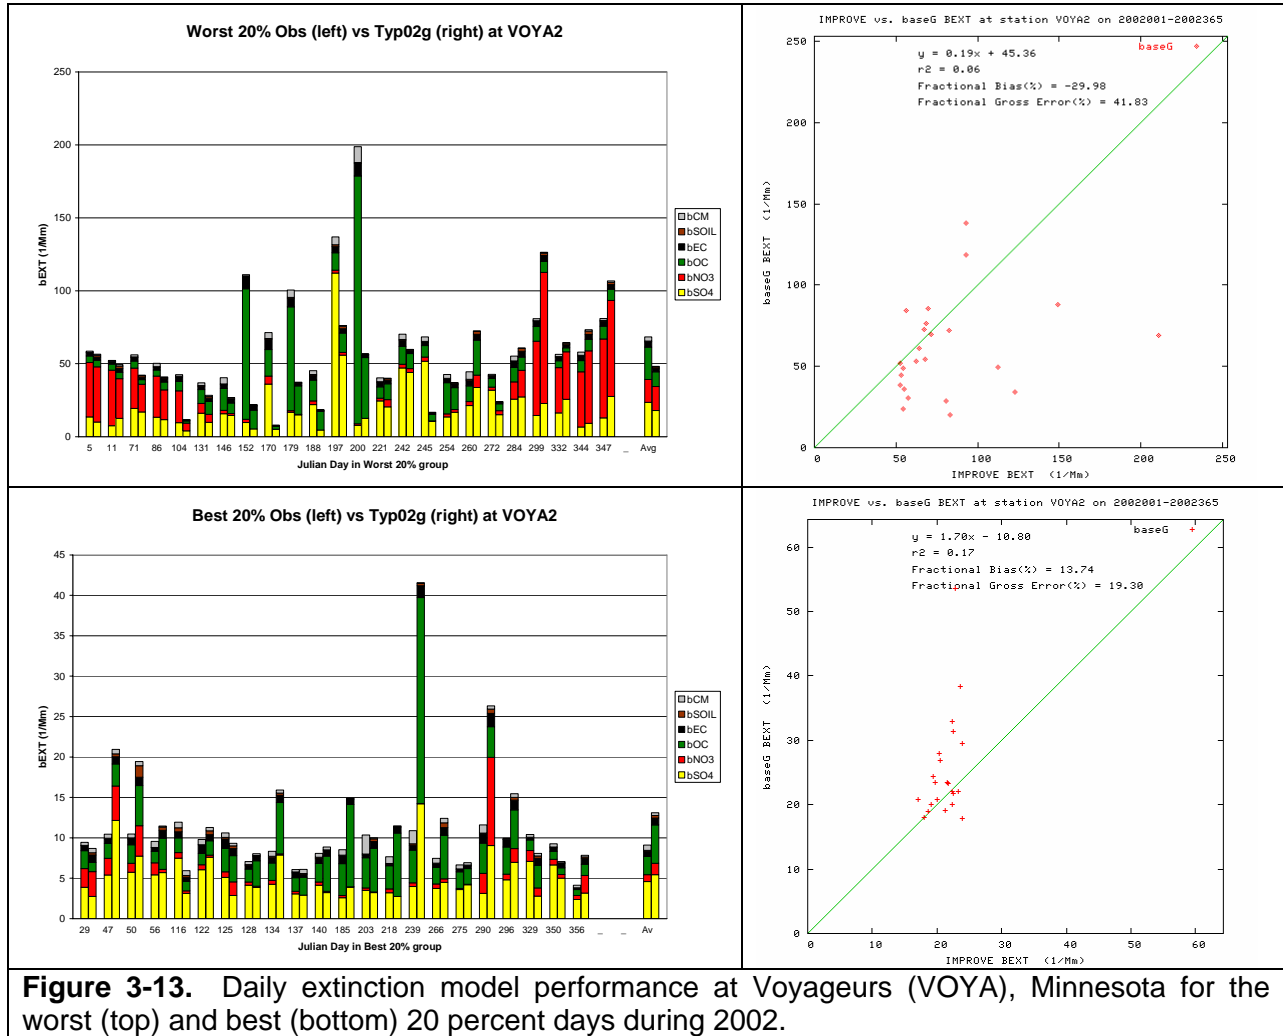

Figure 3-13. Daily extinction model performance at Voyageurs (VOYA), Minnesota for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.6 Hercules Glade (HEGL) Missouri

On most of the worst 20 percent days at HEGL the observed extinction ranges from 120 to 220 Mm^{-1} whereas model extinction ranges from 50 to 170 Mm^{-1} (Figure 3-14). However, there is one extreme day with extinction approaching 400 Mm^{-1} that the model does a very good job in replicating. Over all the days there is a modest underestimation bias in SO_4 (-39%) and OMC (-39%) extinction, larger underestimation bias in EC (-62%) and CM (-118%) extinction and overestimation bias in Soil (+30%) extinction (Figure C-53).

On the best 20 percent days there is one day where the model overstates the observed extinction by approximately a factor of four and a handful of other days that the model overstates the extinction by a factor of 2 or so, but most of the days both the model and observed extinction sites are around 40 $Mm^{-1} \pm 10 Mm^{-1}$. On the best 20 percent days, when the observed extinction is overstated, it is due to overstatement of the NO_3 .

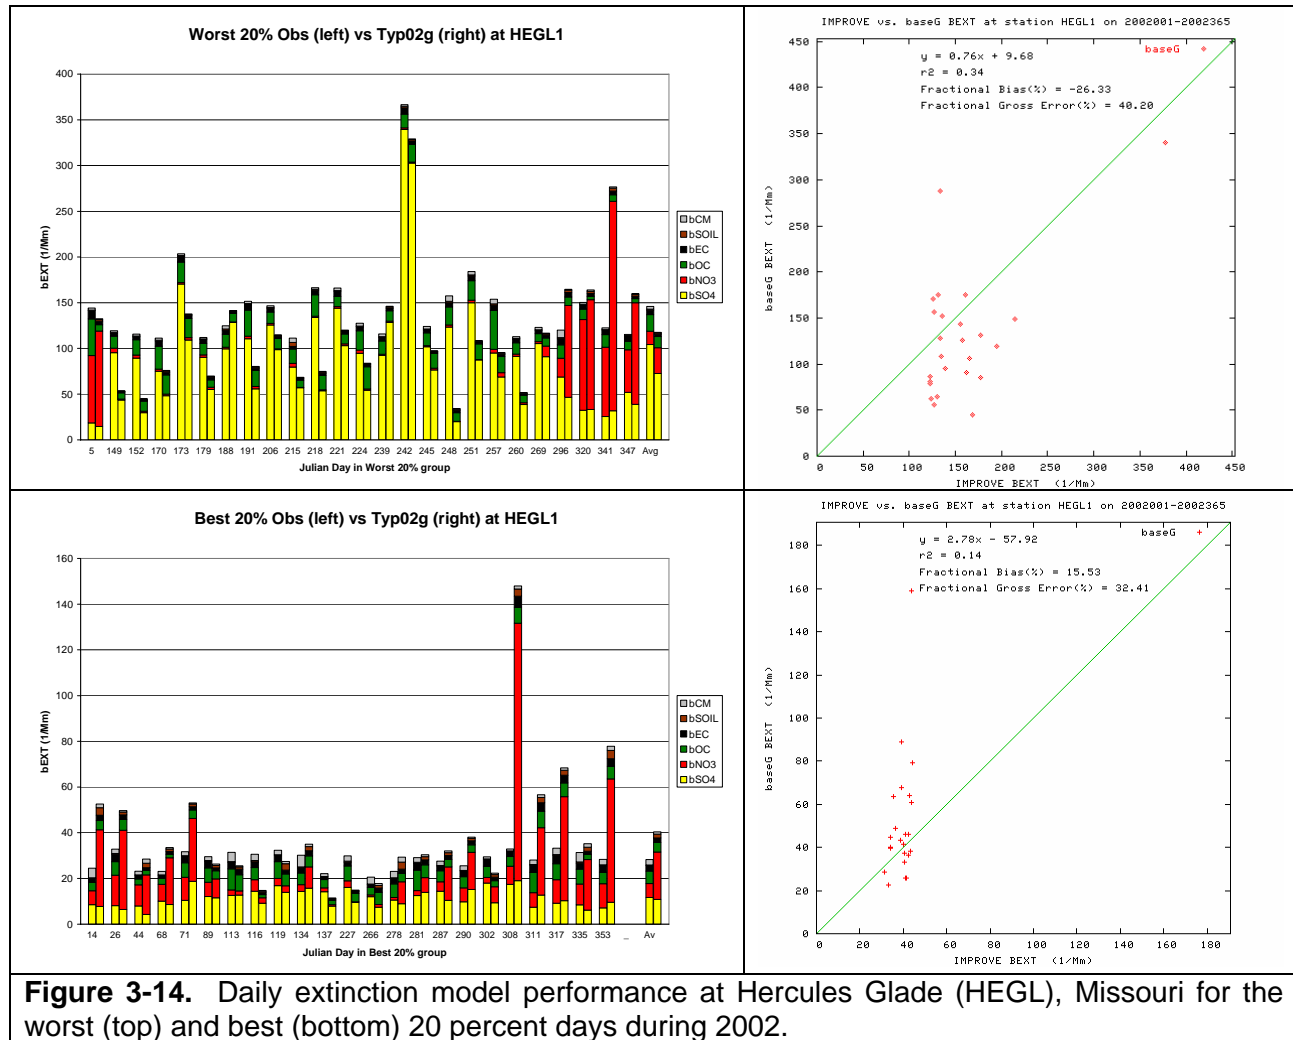

Figure 3-14. Daily extinction model performance at Hercules Glade (HEGL), Missouri for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.7 Mingo (MING) Missouri

The worst 20 percent days at MING are mainly high SO4 days with a few high NO3 days that the model reproduces reasonably well resulting in low bias (+10%) and error (38%) for total extinction (Figure 3-15). The PM species specific performance is fairly good with low bias for SO4 (+4%), good agreement with NO3 on high NO3 days except for one day, low OMC (+23%) and EC (+3%) bias and larger bias in EC (+37%) and CM (-105%) extinction (Figure C-54).

For the best 20 percent days, there is one day the model is way too high due to overstated NO3 extinction and a few other days the model overstates the observed extinction that is usually due to overpredicted NO3, but on most of the best 20 percent days the modeled extinction is comparable to the observed values. This results in low bias (+12%) and error (36%) for total extinction at MING for the best 20 percent days.

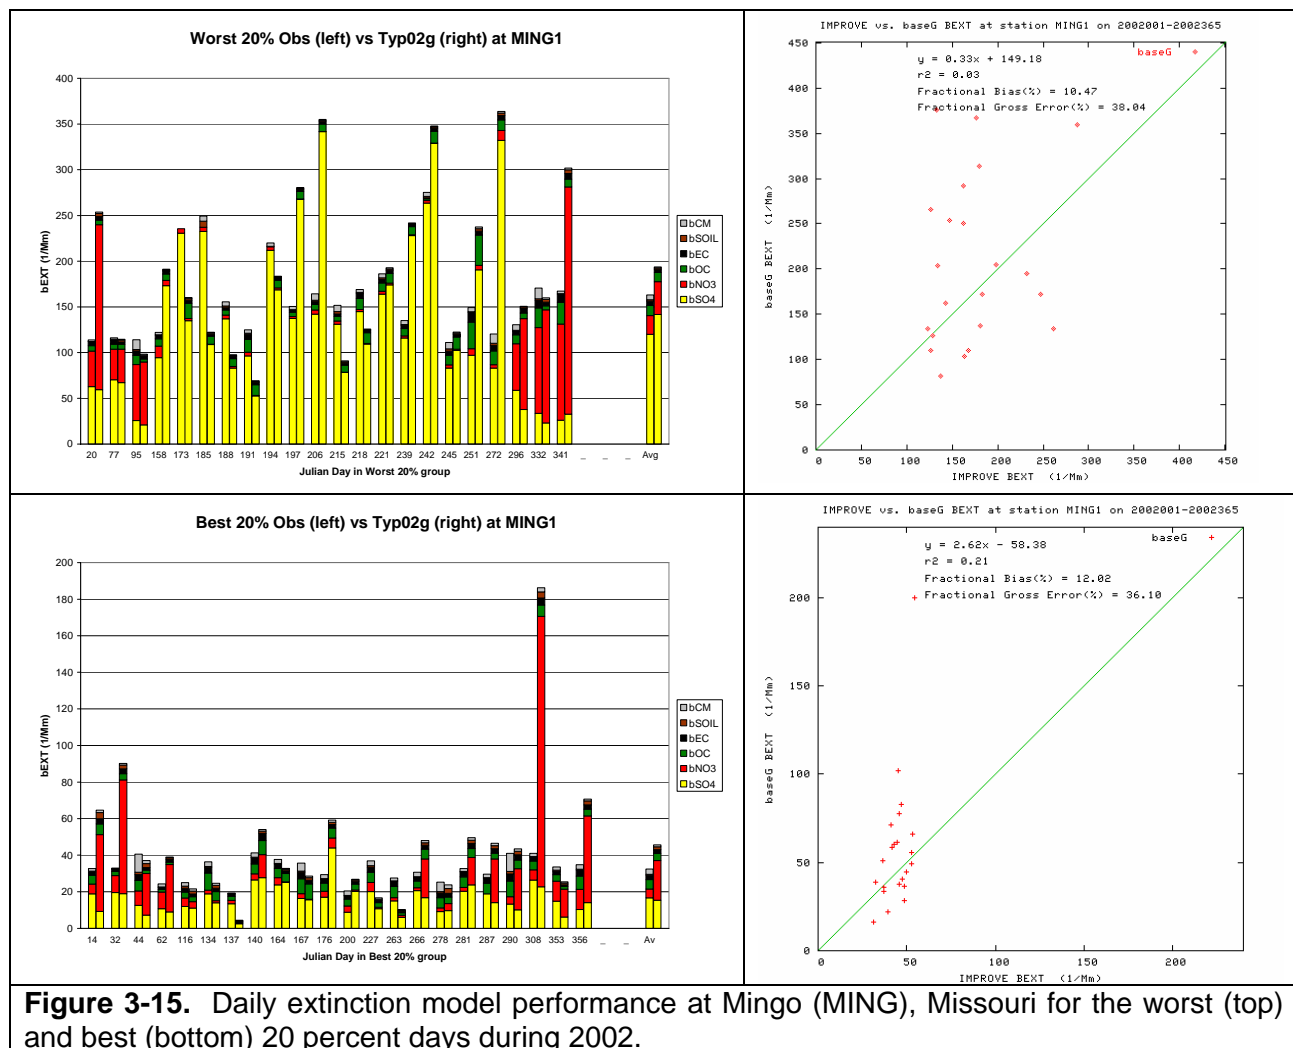

Figure 3-15. Daily extinction model performance at Mingo (MING), Missouri for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.8 Wichita Mountains (WIMO), Oklahoma

With the exception of an overprediction on day 344 due to NO₃, observed total extinction on the worst 20 percent days at WIMO is understated with a bias of -42% (Figure 3-16) that is primarily due to an underestimation of extinction due to SO₄ (-48%) and OMC (-69%) (Figure C-55).

CMAQ total extinction performance for the average of the best 20 percent days at WIMO is characterized by an overestimation bias (+21%) on most days that is primarily due to NO₃ overprediction on several days. Again the modeled range of extinction on the best 20 percent days (12-60 Mm⁻¹) is much greater than observed (20-35 Mm⁻¹).

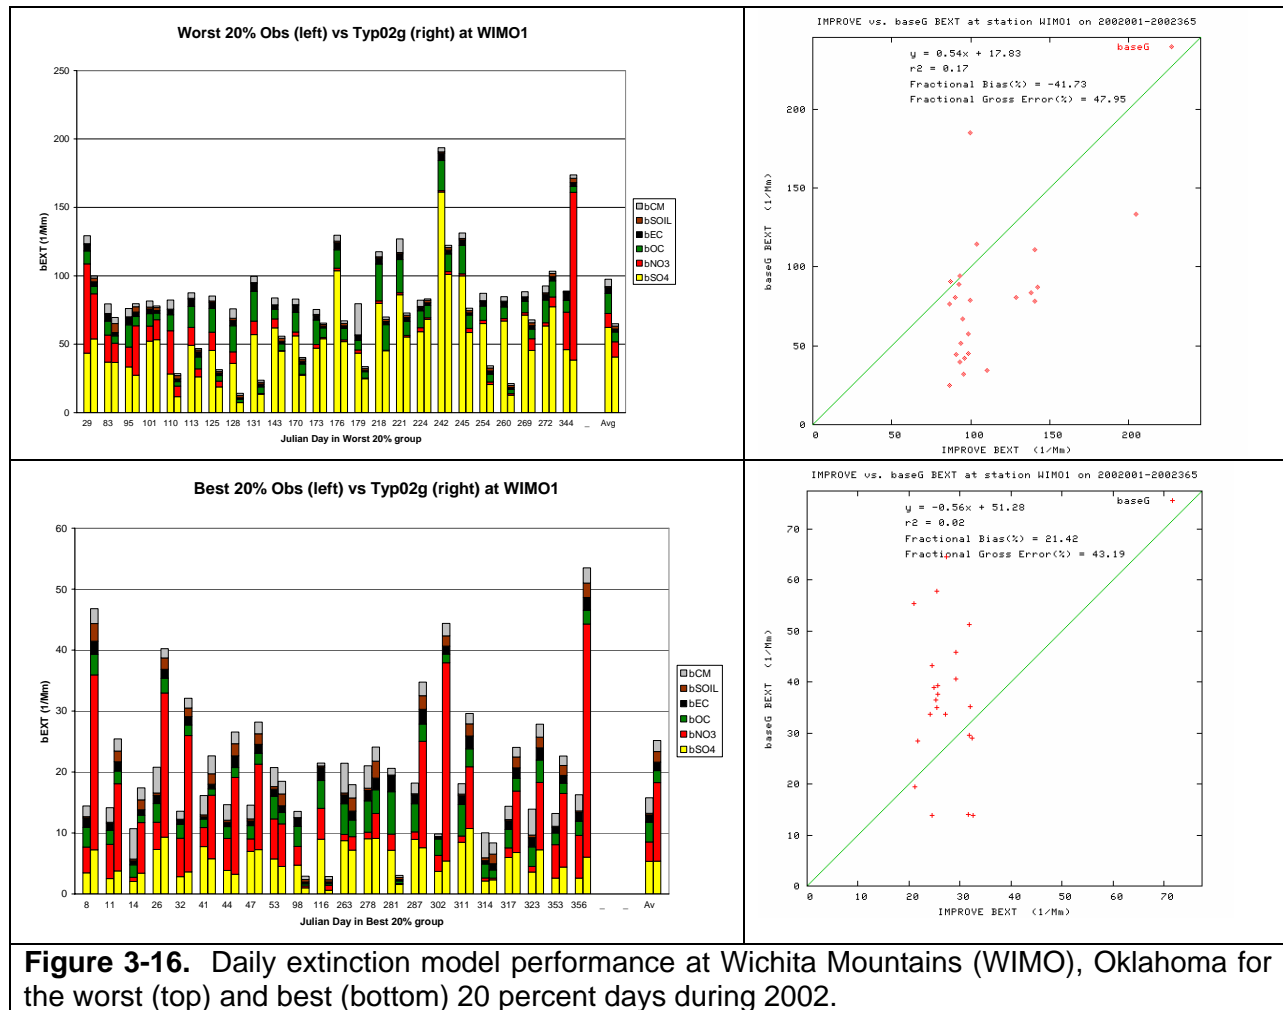

Figure 3-16. Daily extinction model performance at Wichita Mountains (WIMO), Oklahoma for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.9 Big Bend (BIBE) Texas

The observed extinction on the worst 20 percent days at BIBE is underpredicted on almost every day resulting in a fractional bias value of -72% (Figure 3-17). Every component of extinction is underestimated on average for the worst 20 percent days (Figure C-56) with the underestimation bias ranging from -24% (OMC) to -162% (CM). SO₄ extinction, that typically represents the largest component of the total extinction is understated by -94%.

The model does a better job in predicting the total extinction at BIBE for the best 20 percent days with average fractional bias and error values of +13% and 19% (Figure 3-17). With the exception of one day that the observed extinction is overestimated by approximately a factor of 2, the modeled and observed extinction on the best 20 percent days at BIBE are both within 12 to 25 Mm⁻¹. However, there are some mismatches with the components of extinction with the model estimating much lower contributions due to Soil and CM.

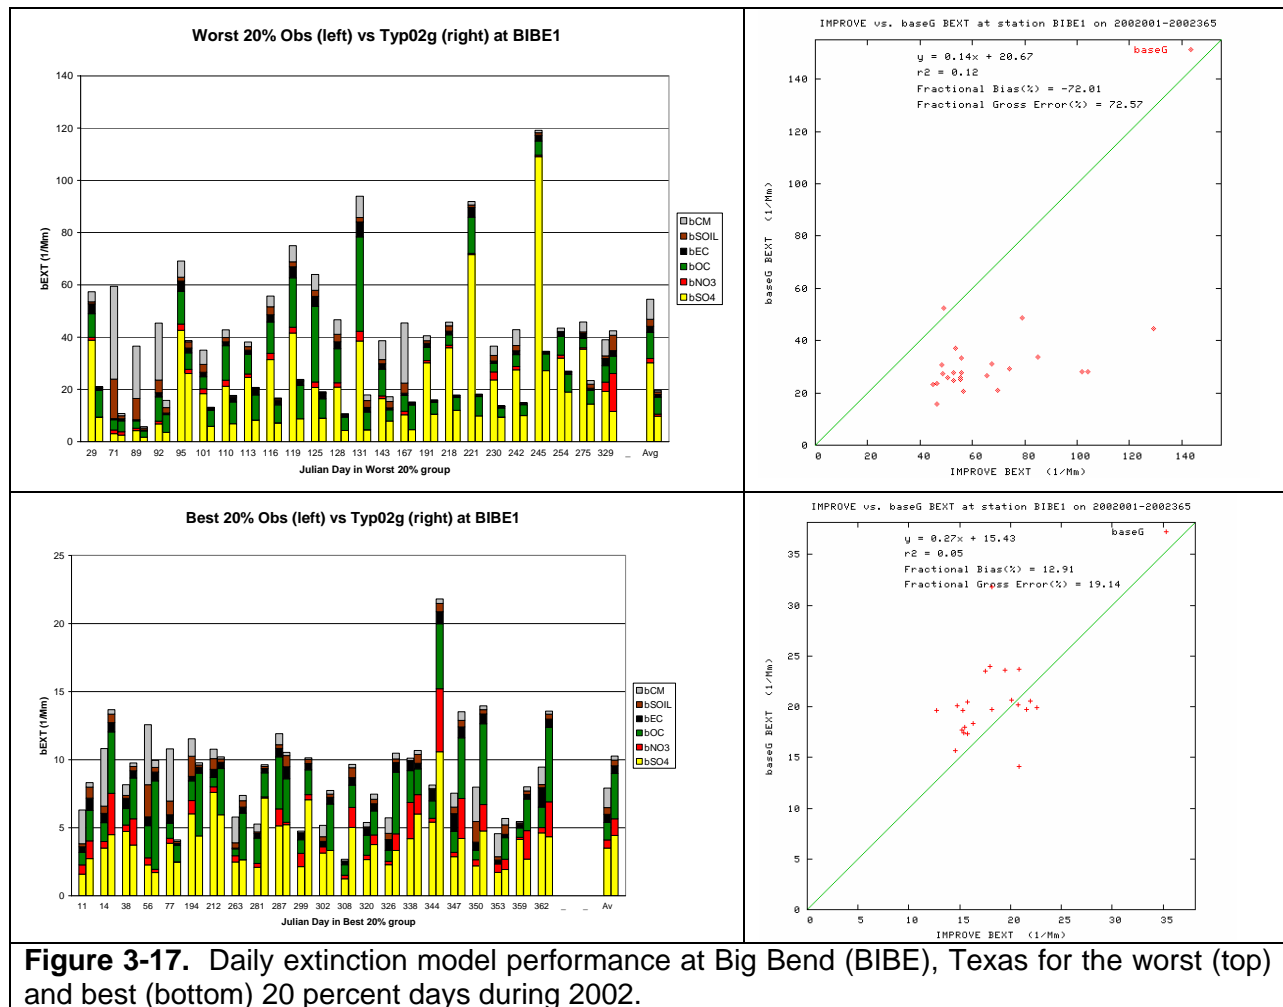

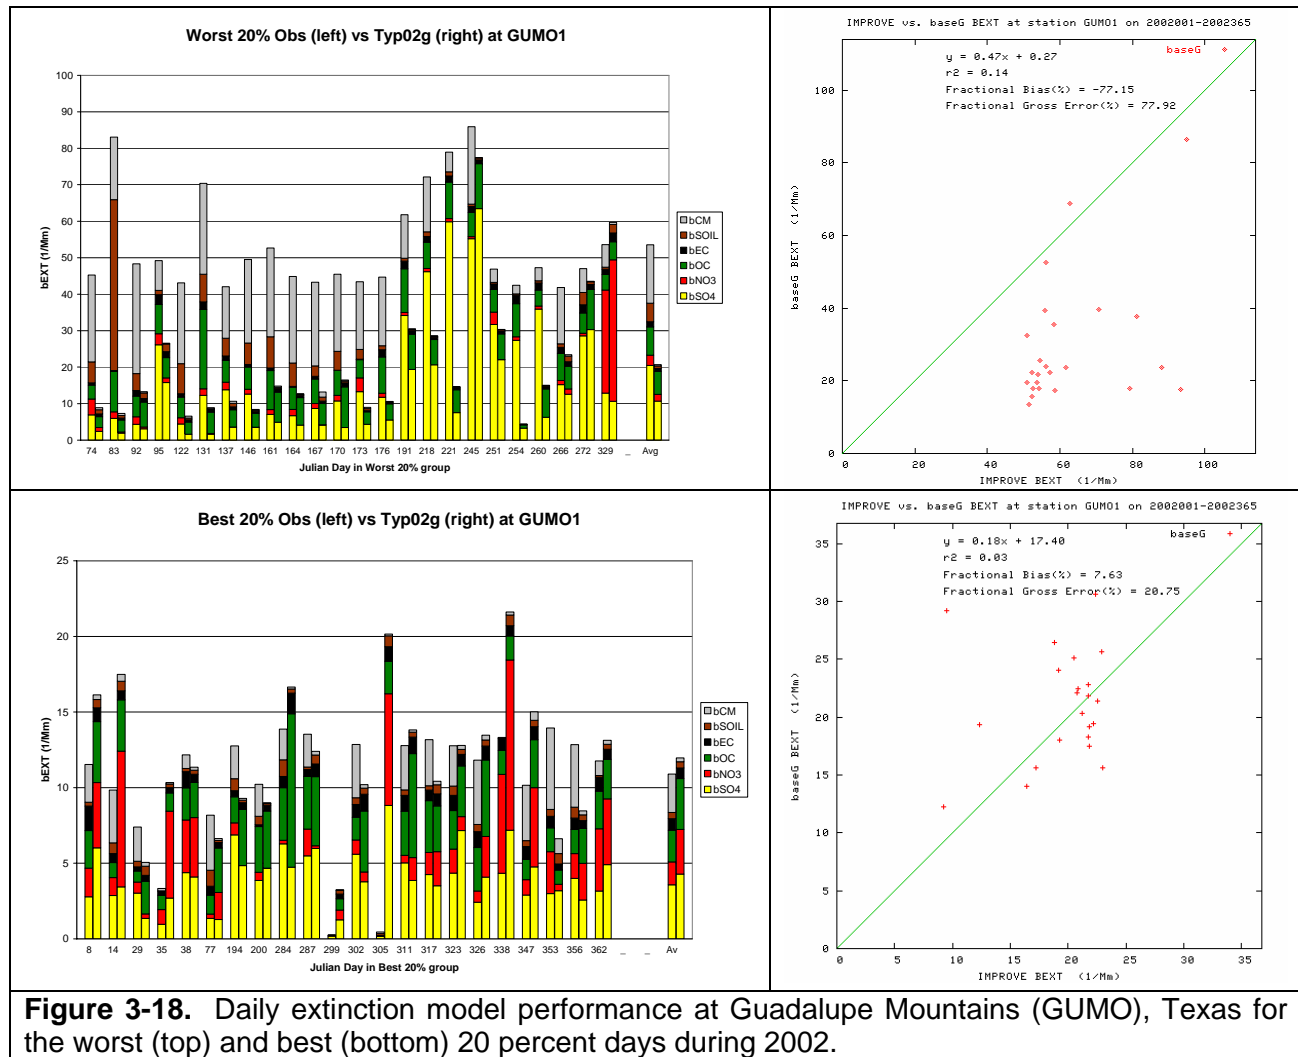

Figure 3-17. Daily extinction model performance at Big Bend (BIBE), Texas for the worst (top) and best (bottom) 20 percent days during 2002.

3.7.10 Guadalupe Mountains (GUMO) Texas

Most of the worst 20 percent days at GUMO are high dust days with high Soil and CM that is not captured by the model (Figure 3-18). Extinction due to Soil and CM on the worst 20 percent days is underestimated by -105% and -191%, respectively (Figure C-57). Better performance is seen on the best 20 percent days with bias and error for total extinction of 8% and 21%, but the model still understates Soil and CM.

3.8 Model Performance Evaluation Conclusions

The model performance evaluation reveals that the model is performing best for SO₄, OMC and EC. Soil performance is mixed with a winter overestimation bias with lower bias and higher error in the summer. CM performance is poor year round. The operational evaluation reveals that SO₄ performance usually achieves the PM model performance goal and always achieves the model performance criteria, although it does have an underestimation bias that is greatest in the summer. NO₃ performance is characterized by a winter overestimation bias with an even greater summer underestimation bias. However, the summer underestimation bias occurs when NO₃ is very low and when it is not an important component of the observed or predicted PM mass concentrations or component of visibility impairment. Performance for OMC meets the model performance goal year round at the IMPROVE sites, but is characterized by an underestimation bias at the more urban STN sites. EC exhibits very low bias at the STN sites and a summer underestimation bias at the IMPROVE sites, but meets the model performance goal throughout the year. Soil has a winter overestimation bias that is outside of the model performance goal and criteria raising questions whether the model should be used for this species. Finally, CM performance is extremely poor with an underprediction bias that is outside of the performance goal and criteria. We suspect that much of the CM concentrations measured at the IMPROVE sites is due to highly localized emissions from fugitive dust sources that are not included in the emissions inventory and would be difficult to simulate using 36 km regional modeling.

Performance for the worst 20 percent days at the CENRAP Class I areas is generally characterized by an underestimation bias. Performance at the BRET, BIBE and GUMO Class I areas for the worst 20 percent days is particularly suspect and care should be taken in the interpretation of the visibility projections at these three Class I areas.

The CMAQ 2002 36 km model appears to be working well enough to reliably make future-year projections for changes in SO₄, NO₃, EC and OMC at the rural Class I areas. Performance for Soil and especially CM is suspect enough that care should be taken in interpreting these modeling results. The model evaluation focused on the model's ability to predict the components of light extinction mainly at the Class I areas. Additional analysis would have to be undertaken to examine the model's ability to simulate ozone and fine particulate to address 8-hour ozone and PM_{2.5} attainment issues.

4.0 VISIBILITY PROJECTIONS

This section presents the future-year visibility projections for Class I areas within and near the CENRAP states and their comparison with the 2018 Uniform Rate of Progress (URP) point. As noted in Chapter 1, the Regional Haze Rule (RHR) requires states with Class I areas to develop State Implementation Plans (SIPs) that include reasonable progress goals (RPGs) for improving visibility in each Class I area and emission reduction measures to meet those goals. For the initial SIPs due in December 2007, states are required to adopt RPGs for improving visibility from Baseline Conditions. The 2000-2004 five-year period is used to define Baseline Conditions and the first future progress period is 2018. A state is required to set RPGs for each Class I area in the state for two visibility metrics:

- Provide for an improvement in visibility for the most impaired visibility days (i.e., the worst 20 percent days); and
- Ensure no degradation in visibility for the least impaired visibility days (i.e., the best 20 percent days).

The goal of the RPGs is to provide for a rate of improvement sufficient to be on a course to attain “Natural Conditions” by 2064. States are to define controls to meet RPGs every 10 years, starting in 2018, which defines progress periods ending in 2018, 2028, 2038, 2048, 2058 and finally 2064. States will determine whether they are meeting their goals by comparing visibility conditions from one five-year period to another (e.g., 2000-2004 to 2013-2017). As stated in 40 CFR 51.308 (d) (1), baseline visibility conditions, reasonable progress goals, and changes in visibility must be expressed in terms of deciview (dv) units. The haze index (HI) metric of visibility impairment, in deciviews, is derived from light extinction (b_{ext}) as follows:

$$HI = 10 \ln (b_{ext}/10),$$

Where light extinction (b_{ext}) is expressed in terms of inverse megameters ($Mm^{-1} = 10^{-6} m^{-1}$). Light extinction (b_{ext}) is calculated using the observed fine particulate concentrations from the IMPROVE monitors using either the original or the new IMPROVE aerosol extinction equation. Both equations are discussed below.

4.1 Guidance for Visibility Projections

EPA has published several guidance documents that relate to how modeling results should be used to project future-year visibility and how states should define RPGs:

“Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$ and Regional Haze” (EPA, 2007a).

“Guidance for Tracking Progress Under the Regional Haze Rule” (EPA, 2003a).

“Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule” (EPA, 2003b).

“Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program” (EPA, 2007b).

The first EPA modeling guidance document listed above (EPA, 2007) discusses the use of modeling results to project future-year visibility. The second EPA guidance document (EPA, 2003a) focuses on monitored visibility, how to define the visibility Baseline Conditions and how to track visibility goals. The third EPA guidance document discusses procedures for defining Natural Conditions for a Class I area. Natural Conditions are the visibility goal for 2064. Although states may propose alternative approaches for defining Natural Conditions, in this section we use the default Natural Conditions at Class I areas (EPA, 2003b; Pitchford, 2006). The final EPA guidance document discusses how states should define their RPGs and their relationship to the 2018 URP point.

The EPA documents discussed above are followed for the visibility projections presented in this section with one notable exception. Some of the EPA documents are based on the original IMPROVE equation (e.g., EPA, 2003a, b). The CENRAP visibility projections are based on the new IMPROVE equation, although projections based on the original IMPROVE equation are also presented as an alternative approach in Chapter 5. EPA guidance allows for using either the original or the new IMPROVE equation (EPA, 2007a; Timin, 2007). CENRAP, along with the other RPOs, have elected to use the new IMPROVE equation for their visibility projections.

4.2 Calculation of Visibility and 2018 URP Point from IMPROVE Measurements

EPA guidance recommends using the model in a relative sense to project future-year visibility conditions (EPA, 2007a). This projection is made using Relative Response Factors (RRFs) that are defined as the ratio of the future-year modeling results to the base-year modeling results. The RRFs are applied to the baseline visibility conditions to project future-year visibility. The major features of EPA’s recommended visibility projection approach are as follows (EPA, 2003a,b; 2007a):

- Monitored data are used to define current visibility Baseline Conditions using IMPROVE monitoring data from the 2000-2004 five-year base period.
- Monitored concentrations of PM₁₀ are divided into six major components, the first five of which are assumed to be PM_{2.5} and the sixth is coarse mass (CM or PM_{2.5-10}).
 - SO₄ (sulfate) that is assumed to be ammonium sulfate [(NH₄)₂SO₄];
 - NO₃ (particulate nitrate) that is assumed to be ammonium nitrate [NH₄NO₃];
 - OC (organic carbon) that is assumed to be total organic mass carbon (OMC)
 - EC (elemental carbon);
 - IP (other fine inorganic particulate or Soil); and
 - CM (coarse mass).
- Models are used in a relative sense to develop RRFs between baseline and future predicted concentrations of each component.

September 2007

- PM component-specific RRFs are multiplied by observed Baseline monitored values to estimate future-year PM component concentrations.
- Estimates of future-year component concentrations are consolidated to provide an estimate of future-year air quality and visibility using either the original or new IMPROVE equation.
- Future-year model projected visibility is compared with the 2018 point on the URP glidepath to assist in evaluating the visibility improvements.
- It is assumed that all measured sulfate is in the form of ammonium sulfate $[(\text{NH}_4)_2\text{SO}_4]$ and all particulate nitrate is in the form of ammonium nitrate $[\text{NH}_4\text{NO}_3]$.

In order to facilitate tracking visibility progress, three important visibility concepts are required for each Class I area:

Baseline Conditions: Baseline Conditions represent visibility for the 20 percent best (B20%) and 20 percent worst (W20%) visibility days for the initial five-year baseline period of the regional haze program. Baseline Conditions are calculated using IMPROVE monitor data collected during the 2000-2004 five-year period and are the starting point in 2004 for the URP glidepath and 2018 visibility projections.

Natural Conditions: Estimates of natural visibility conditions for the best 20 percent and worst 20 percent days at a Class I area (i.e., visibility conditions that would be experienced in the absence of human-caused impairment). EPA has defined a set of default Natural Conditions for the original IMPROVE equation (EPA, 2003b) that has been updated to the new IMPROVE equation by the Natural Haze Levels II Committee (Pitchford, 2006) that we have used in this Chapter.

2018 URP Point: The 2018 Uniform Rate of Progress (URP) point is defined by defining a linear glidepath in deciviews starting with the 2000-2004 Baseline Conditions in 2004 and ending at Natural Conditions in 2064. Where the linear glidepath passes through 2018 is the 2018 URP point in deciviews.

4.2.1 Calculation of Visibility from IMPROVE PM Measurements

Baseline Conditions for Class I areas are calculated using the procedures in EPA's guidance document (EPA, 2003a) and fine and coarse particulate matter concentrations measured at IMPROVE monitors (Malm et al, 2000; Debell et al., 2006). Currently, each Class I area in the CENRAP domain has an associated IMPROVE monitor. The IMPROVE monitors do not directly measure visibility, but instead measure speciated fine particulate ($\text{PM}_{2.5}$) and total $\text{PM}_{2.5}$ and PM_{10} mass concentrations from which visibility is obtained through the IMPROVE equation.

Visibility conditions are estimated starting with the IMPROVE 24-hour average mass measurements for six PM species:

- Sulfate [(NH₄)₂SO₄];
- Particulate Nitrate [(NH₄NO₃);
- Organic Matter Carbon or Organic Mass by Carbon [OMC];
- Elemental Carbon [EC] or Light Absorbing Carbon [LAC];
- Other fine particulate [Soil]; and
- Coarse Matter or Coarse Mass [CM].

The IMPROVE monitors do not directly measure some of these species so assumptions are made as to how the IMPROVE measurements can be adjusted and combined to obtain these six components of light extinction. For example, in the IMPROVE equation sulfate and particulate nitrate are assumed to be completely neutralized by ammonium. In addition, only the fine mode (PM_{2.5}) of PM is speciated by the IMPROVE monitor to obtain sulfate and nitrate measurements (that is, any coarse mode sulfate and nitrate in the real atmosphere may be present in the CM IMPROVE measurement). Concentrations for the above six components of light extinction in the IMPROVE equation are obtained from the IMPROVE measured species using the mappings shown in Table 4-1:

Table 4-1. Definition of IMPROVE PM Components from Measured IMPROVE Species.

IMPROVE Component	IMPROVE Measured Species
Sulfate	1.375 x (3 x S)
Nitrate	1.29 x NO ₃ ⁻
OMC	1.4*OC (original IMPROVE) and 1.8*OC (new IMPROVE)
LAC	EC
Soil	2.2*AL + 2.49*SI + 1.63*CA + 2.42*FE + 1.94*TI
CM	MT – MF

Where:

- S is elemental sulfur as determined from proton induced x-ray emissions (PIXE) analysis of the IMPROVE Module A¹. To estimate the mass of the sulfate ion (SO₄⁻), S is multiplied by 3 to account the presence of oxygen. If S is missing then the sulfate (SO₄) measured by ion chromatography analysis of the Module B is used to replace (3 x S). For the IMPROVE aerosol extinction calculation, Sulfate is assumed to be completely neutralized by ammonium (1.375 x SO₄).
- NO₃⁻ is the particulate nitrate measured by ion chromatography analysis of the Module B. For the IMPROVE aerosol extinction calculation, it is assumed to be completely neutralized by ammonium (1.29 x NO₃⁻).
- The IMPROVE Organic Carbon (OC) measurements are multiplied by 1.4 to obtain Organic Mass Carbon (OMC) using the original IMPROVE equation and multiplied by 1.8 for the new IMPROVE equation. This adjustment of the measured OC accounts for mass due to other elements in the OMC besides Carbon.
- Elemental Carbon (EC) is also referred to as Light Absorbing Carbon (LAC).

¹ The IMPROVE sampler consists of four independent modules (A, B, C and D). Each module incorporates a separate inlet, filter pack and pump assembly and are controlled by a common timing mechanism. Module A measures fine PM mass and elements. Module B measures sulfate and nitrate ions. Module C measures EC and OC. Module D measures PM₁₀ mass. (see <http://vista.cira.colostate.edu/improve/> for more details).

- Soil is determined as a sum of the masses of those elements (measured by PIXE) predominantly associated with soil (Al, Si, Ca, Fe, K and Ti), adjusted to account for oxygen associated with the common oxide forms. Since K and FE are products of the combustion of vegetation, they are both represented in the formula by 0.6 x Fe and K is not shown explicitly.
- MT and MF are total PM₁₀ and PM_{2.5} mass, respectively.

4.2.1.1 Original and New IMPROVE Equations

Associated with each PM species is an extinction efficiency that converts concentrations (in µg/m³) to light extinction (in inverse megameters, Mm⁻¹). Sulfate and nitrate are hygroscopic which means that they can absorb water from the atmosphere which changes their extinction efficiency. This is accounted for through relative humidity adjustment factors [f(RH)] that increase the particle’s extinction efficiency with increasing RH to account for the particles taking on water. Note that some OMC may also have hygroscopic properties, but the IMPROVE equations assume OMC is non-hygroscopic.

There are currently two IMPROVE equations that are used to convert the measured PM concentrations to light extinction, the original (or old) and the new IMPROVE equations.

4.2.1.1.1 Original IMPROVE Equation

The original IMPROVE equation that converts PM species concentrations to light extinction is given as follows:

$$\begin{aligned}
 b_{\text{Sulfate}} &= 3 \times f(\text{RH}) \times [\text{Sulfate}] \\
 b_{\text{Nitrate}} &= 3 \times f(\text{RH}) \times [\text{Nitrate}] \\
 b_{\text{EC}} &= 10 \times [\text{EC}] \\
 b_{\text{OMC}} &= 4 \times [\text{OMC}] \\
 b_{\text{Soil}} &= 1 \times [\text{Soil}] \\
 b_{\text{CM}} &= 0.6 \times [\text{CM}]
 \end{aligned}$$

Monthly average f(RH) factors are used as recommended in EPA’s guidance (EPA, 2003a). These values are available in the final EPA guidance document (EPA, 2003a) and at: ftp://ftp.saic.com/raleigh/RegionalHaze_2002FRHcurve/fRH_analysis/.

The total light extinction (b_{ext}) is assumed to be the sum of the light extinction due to the six PM species listed above plus Rayleigh (blue sky) background (b_{Ray}) that is assumed to be 10 Mm⁻¹.

$$b_{\text{ext}} = b_{\text{Ray}} + b_{\text{Sulfate}} + b_{\text{Nitrate}} + b_{\text{EC}} + b_{\text{OMC}} + b_{\text{Soil}} + b_{\text{CM}}$$

The total light extinction (b_{ext}) in Mm⁻¹ is related to visual range (VR) in km using the following relationship:

$$\text{VR} = 3912 / b_{\text{ext}},$$

for b_{ext} in Mm^{-1} .

The Regional Haze Rule requires that visibility be expressed in terms of a haze index (HI) in units of deciviews (dv), which is calculated as follows:

$$HI = 10 \ln(b_{ext}/10)$$

4.2.1.1.2 New IMPROVE Equation

The new IMPROVE equation is nonlinear in SO₄, NO₃ and OMC concentrations accounting for the different light scattering efficiency characteristics as a function of concentrations for these three species. It is expressed as follows:

$$\begin{aligned} b_{Sulfate} &= 2.2 \times f_S(RH) \times [Small\ Sulfate] + 4.8 \times f_S(RH) \times [Large\ Sulfate] \\ b_{Nitrate} &= 2.4 \times f_S(RH) \times [Small\ Nitrate] + 5.1 \times f_S(RH) \times [Large\ Nitrate] \\ b_{EC} &= 10 \times [Elemental\ Carbon] \\ b_{OMC} &= 2.8 \times [Small\ Organic\ Mass] + 6.1 \times [Large\ Organic\ Mass] \\ b_{Soil} &= 1 \times [Fine\ Soil] \\ b_{CM} &= 0.6 \times [Coarse\ Mass] \\ b_{NaCl} &= 1.7 \times f_{SS}(RH) \times [Sea\ Salt] \\ b_{NO2} &= 0.33 \times [NO_2\ (ppb)] \end{aligned}$$

The total Sulfate, Nitrate and OMC are each split into two fractions, representing small and large size distributions of those components. As noted in Table 4-1, the OMC is 1.8 times the IMPROVE OC measurement in the new IMPROVE algorithm, compared to 1.4 times the IMPROVE OC measurement in the original IMPROVE equation. New terms have been added for Sea Salt (important for coastal areas and possibly other areas) and for light absorption by NO₂ (only used where NO₂ observations are available). As none of the CENRAP Class I area IMPROVE sites measure NO₂ concentrations, then this component of the new IMPROVE equations was not used. Site-specific Rayleigh scattering for each IMPROVE monitoring site is used in the new IMPROVE equation, as compared to a constant 10 Mm^{-1} value assumed in the original IMPROVE equation.

The apportionment of the Small and Large components of Sulfate, Nitrate and Organic Mass is done as follows:

$$\begin{aligned} [Large\ Sulfate] &= [Total\ Sulfate] / 20 \times [Total\ Sulfate], \text{ for } [Total\ Sulfate] < 20 \mu\text{g}/\text{m}^3 \\ [Large\ Sulfate] &= [Total\ Sulfate], \text{ for } [Total\ Sulfate] \geq 20 \mu\text{g}/\text{m}^3 \\ [Small\ Sulfate] &= [Total\ Sulfate] - [Large\ Sulfate] \end{aligned}$$

The same equations are used to apportion Total Nitrate and Total OMC among their Large and Small components.

The total extinction (b_{ext}) in the new IMPROVE equations is the sum of all the extinction components associated with each PM species. The new IMPROVE equation adds Sea Salt and

NO₂ as noted above. In addition, site-specific Rayleigh background is used with the new IMPROVE equation:

$$b_{\text{ext}} = b_{\text{Ray}} + b_{\text{Sulfate}} + b_{\text{Nitrate}} + b_{\text{EC}} + b_{\text{OMC}} + b_{\text{Soil}} + b_{\text{CM}} + b_{\text{NaCl}} + b_{\text{NO}_2}$$

The Haze Index (HI) and Visual Range (VR) are calculated from the total extinction from the new IMPROVE equation using the same formulas as given above for the original IMPROVE equation.

4.2.1.1.3 Justification for Using the New IMPROVE Equation

The new IMPROVE equation was developed using the latest scientific information on PM species extinction properties combined with fitting reconstructed light extinction based on IMPROVE measured PM and NO₂ concentrations with actual co-located measured light extinction (e.g., nephelometer measurements). Figure 4-1 displays example comparisons of 24-hour light extinction using the original and new IMPROVE equations compared against 24-hour nephelometer measurements of light extinction at the Great Smoky Mountains Class I area IMPROVE monitor. The original IMPROVE equation has a bias toward understating light extinction at the high end and overstating it at the low end, whereas the new IMPROVE equation does a better job in estimating light extinction from measured PM at all extinction levels. Because the new IMPROVE equation is based on more recent science and fits the observed light extinction values better, the CENRAP states have elected to perform their primary visibility projections using the new IMPROVE equation. Results using the original IMPROVE equation are presented in Section 5 as an alternative approach.

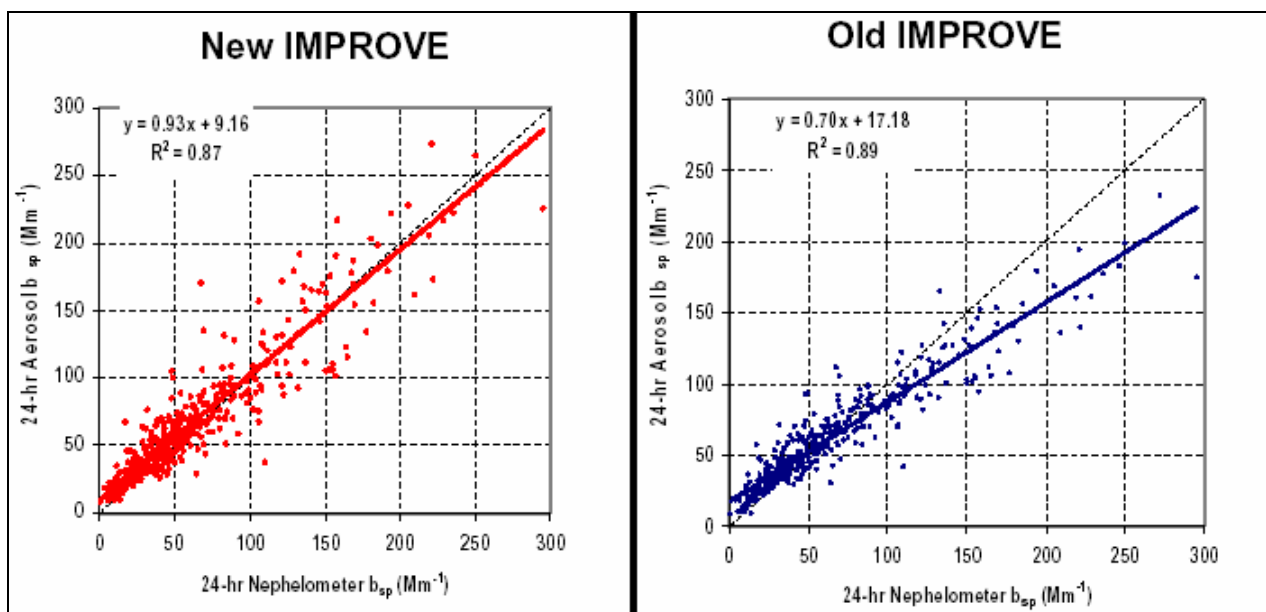

Figure 4-1. Comparisons of observed light extinction with reconstructed light extinction using the new (left) and original (right) IMPROVE equations at the Great Smoky Mountains National Park.

4.2.2 Calculation of the Baseline Conditions

The visibility Baseline Conditions for the worst 20 percent and best 20 percent days is calculated from the IMPROVE observations from the 2000-2004 period for each Class I area following EPA's guidance (EPA, 2003a). The basic procedures for calculating the Baseline Conditions are as follows:

1. Determine whether the observed IMPROVE data for each site and year satisfies EPA's minimal data capture criteria (EPA, 2003a). If there are less than three years with valid data capture for the 2000-2004 Baseline then the Baseline Conditions can not be calculated and data filling is needed.
2. For each year in the 2000-2004 period with sufficient valid data, rank the visibility in terms of extinction or deciview using either the original or new IMPROVE equation and monthly average $f(RH)$ factors (EPA, 2003a).
3. For the worst 20 percent days, extract the 20% most impaired visibility days for each year (similarly for best 20 percent days extract 20% cleanest days). With a complete yearly data capture of IMPROVE 1:3 day sampling frequency this would result in 24 worst 20 percent and 24 best 20 percent days in a year.
4. For each worst 20 percent (or best 20 percent) day in each year, calculate 24-hour average visibility extinction using the IMPROVE measurements and either the original and new IMPROVE equation, convert the daily extinction to daily deciview and then average across each year to get yearly average deciview extinction for the worst 20 percent (or best 20 percent) days for each valid year from the 2000-2004 period.
5. Average the annual average deciview worst 20 percent (or best 20 percent) days deciview across each valid year in the 2000-2004 period (minimum of 3 valid years required) to get the worst 20 percent (or best 20 percent) Baseline Conditions.

4.2.3 Data Filling for Sites with Insufficient Valid Data to Calculate Baseline Conditions

Three CENRAP Class I areas did not contain sufficient IMPROVE observations during the five-year 2000-2004 Baseline to have three valid years of data from which Baseline Conditions could be constructed: Breton Island (BRET), Louisiana; Boundary Waters (BOWA), Minnesota and Mingo (MING), Missouri. For these three Class I areas, data filling was used to obtain sufficient data so that at least three-years of valid data were available from which Baseline Conditions could be calculated. These data filled IMPROVE databases were prepared and made available on the VIEWS website. More information on the data filling procedures can be found at the VIEWS website: (<http://vista.cira.colostate.edu/views/>).

4.2.4 Natural Conditions

EPA has published default Natural Conditions for Annual Average and the worst 20 percent and best 20 percent days based on the original IMPROVE equation (EPA, 2003b). These default Natural Conditions have been updated to the new IMPROVE equation by the Natural Haze Levels II Committee (Pitchford, 2006). These default Natural Conditions are used as the anchor point for the glidepaths in 2064 and are provided in Appendix D for the CENRAP Class I areas.

4.2.5 2018 URP Point

The 2018 point on the Uniform Rate of Progress (URP) glidepath is constructed by generating a linear glidepath in deciviews from the Baseline Conditions in 2004 to Natural Conditions in 2064. Where the linear glidepath crosses 2018 is the 2018 URP point or the 2018 URP point. Figure 4-2 displays an example linear glidepath for the Caney Creek Class I area in Arkansas. There are three years of sufficient valid IMPROVE data during the 2000-2004 Baseline (2002, 2003 and 2004) with values of 27.21, 26.52 and 25.34 dv resulting in worst 20 percent Baseline Conditions of 26.36 dv that is placed as the starting point in 2004 for the glidepath. The ending point for the glidepath is 11.58 dv which is the default Natural Conditions for the worst 20 percent days (EPA, 2003b; Pitchford, 2006). The linear glidepath crosses 2018 at 22.91 dv which becomes the 2018 URP point.

Figure 4-2. Linear Glidepath for Caney Creek (CACR), Arkansas that linearly connects the 26.36 dv Baseline Conditions in 2004 with the 11.58 dv Natural Conditions in 2064 resulting in a 22.91 dv 2018 URP Point.

4.3 EPA Default Approach to Visibility Projections

For CENRAP’s model application for a single year (2002), EPA’s regional haze modeling guidance recommends developing Class I area-specific and PM species-specific RRFs based on the average concentrations for the worst 20 percent days from 2002 (EPA, 2007). Thus, this is

the methodology used to project 2018 visibility estimates in this section. For example, if $SO_4(2002)_i$ and $SO_4(2018)_i$ are the model estimated sulfate concentrations for the 2002 worst 20 percent days ($i=1\dots N$) at a given Class I area for the 2002 and 2018 emission scenarios then the RRF for sulfate and this Class I area is given by:

$$RRF(SO_4)_i = \frac{\sum SO_4(2018)_i}{\sum SO_4(2002)_i}$$

4.3.1 Mapping of Modeling Results to the IMPROVE Measurements

As noted above, to project future-year visibility at Class I areas the modeling results are used in a relative sense to scale current observed visibility for the worst 20 percent and best 20 percent visibility days using RRFs that are the ratio of modeling results for the future-year to current-year. This scaling is done separately for each of the six components of light extinction in the IMPROVE equations. The CMAQ modeled species do not necessarily exactly match up with the IMPROVE PM species, thus assumptions must be made to map the modeled species to the IMPROVE PM species for the purpose of projecting visibility improvements. For example, CMAQ explicitly simulates ammonium and sulfate may or may not be fully neutralized in the model by ammonium, whereas the IMPROVE equations assume sulfate is fully neutralized by ammonium. For the CMAQ Version 4.5 (September 15, 2005 release) model, the mapping of modeled species to IMPROVE equation PM species is listed in Table 4-2.

Table 4-2. Mapping of CMAQ V4.5 modeled species concentrations to IMPROVE PM components.

IMPROVE Component	CMAQ V4.3 Species
Sulfate	1.375 x (ASO4J + ASO4I)
Nitrate	1.29 x (ANO3J + ANO3I)
LAC	AECJ + AECI
OMC	AORGAJ + AORGAI + AORGP AJ + AORGP AI + AORGBJ + AORGBI
Soil	A25J + A25I
CM	ACORS + ASEAS + ASOIL

For the CENRAP visibility projections using the 2002 Typical and 2018 base case Base G emission scenarios, the secondary organic aerosol (SOA) module in CMAQ V4.5 was modified (SOAmods) to include additional processes related to the generation of SOA from biogenic emissions. In particular, three new species have been added that represent SOA products from biogenic emission compounds that is not included in the standard version of CMAQ V4.5 (Morris et al., 2006c):

- ASOC1 – SOA from biogenic sources (e.g., terpenes and isoprene) that has become polymerized so is no longer volatile.
- ASOC2 – SOA from biogenic sesquiterpene and higher reactivity and higher yield monoterpene emissions.
- ASOC3 – SOA from biogenic isoprene emissions.

Thus, the species mapping for Organic Mass Carbon (OMC) and the CMAQ V4.5 SOAmods version of the model used in CENRAP 2018 visibility projections is as given in Table 4-2 only with the addition of the three new biogenic SOA species to OMC as follows:

$$\text{OMC} = \text{AORGAI} + \text{AORGAI} + \text{AORGPBJ} + \text{AORGPBI} + \text{AORGBJ} + \text{AORGBI} + \text{ASOC1} + \text{ASOC2} + \text{ASOC3}$$

4.3.2 Using Modeling Results to Project Changes in Visibility

Modeling results are used in a relative fashion to project future-year visibility using relative response factors (RRFs). RRFs are expressed as the ratio of the modeling results for the future-year to the results of the base year (2018/2002) and are Class I area and PM species specific. RRFs are applied to the Baseline Condition observed PM species to project future-year PM levels from which visibility can be assessed using the IMPROVE equations listed above. The following six steps are used to project future-year visibility for the worst 20 percent and best 20 percent visibility days (discussion is for worst 20 percent days but also applies to best 20 percent days):

1. For each Class I area and each monitored day, daily visibility is ranked using IMPROVE data and IMPROVE equation (either original or new IMPROVE equation) for each year from the five-year baseline period (2000-2004) to identify the worst 20 percent visibility days for each year from the five-year baseline (see Baseline Conditions discussion above).
2. Use an air quality model to simulate a base year period (ideally the five-year Baseline period of 2000-2004, but for CENRAP just the 2002 annual period was simulated) and a future-year (e.g., 2018) and use the resulting information to develop Class I area-specific RRFs for each of the six components of light extinction in the IMPROVE equation (SO₄, NO₃, EC, OMC, Soil and CM).
3. Multiply the RRF times the measured 24-hour PM concentration data for each day from the worst 20 percent days in each year from the five-year Baseline period to obtain projected future-year 24-hour PM concentrations for the worst 20 percent days and the five-year Baseline.
4. Compute the future-year daily extinction using the IMPROVE equation and the projected PM concentrations for each of the worst 20 percent days in the five-year baseline from Step 3.
5. For each of the worst 20 percent days within each year of the five-year baseline, convert the future-year daily extinction to deciview and average the daily deciview values within each of the five years separately to obtain five-years (or as many years with valid data in the 2000-2004 Baseline) of average deciview visibility for the worst 20 percent days.
6. Average the five-years of average deciview visibility to obtain the future-year visibility Haze Index estimate that is the future-year estimated visibility.

In calculating the RRFs, EPA draft guidance recommends selecting estimated PM species concentrations “near” the monitor by taking a spatial average of PM concentrations across a grid cell resolution dependent NX by NY array of cells centered on the grid containing the monitor. The NX x NY array of cells is grid resolution specific with EPA recommending that NX=NY=1 for 36 km grids, NX=NY=3 for 12 km grids and NX=NY=7 for 4 km grids (EPA, 2007). For the CENRAP 2002 36 km modeling, just the model estimates for the grid cell containing the monitor was used (i.e., NX=NY=1).

4.4 EPA Default 2018 Visibility at CENRAP and Nearby Class I areas and Comparisons to 2018 URP Goals

Using the EPA default visibility projection procedure described in Section 4.3 and the CENRAP 2002 Typical Base G and 2018 Base Case Base G CMAQ modeling results, 2018 visibility projections were made for CENRAP and nearby Class I areas. Appendix D details the 2018 Base G visibility projections for each Class I area in the CENRAP region using the new IMPROVE equation. Results for the Caney Creek (CACR), Arkansas Class I area are discussed in Section 4.4.1 below. Displays for other CENRAP Class I areas are provided in Appendix D and summarized in Section 4.4.2

4.4.1 Example 2018 Base G Visibility Projections for Caney Creek, Arkansas

The 2018 visibility projections for the Caney Creek (CACR), Arkansas Class I area given in Figure D-1 in Appendix D are reproduced in Figure 4-3 and described below.

4.4.1.1 EPA Default 2018 Visibility Projections

The 2018 Base G visibility projection using the EPA default method (EPA, 2007a) and comparison with the 2018 URP point for the worst 20 percent days and the CACR Class I area is shown in Figure 4-3a. The 2000-2004 Baseline Conditions for CACR is 26.36 dv and the 2018 URP point is 22.91 dv so that a 3.45 dv reduction in visibility for the worst 20 percent days is needed to meet the 2018 URP point. The 2018 Base G CMAQ projected visibility is 22.48 dv so that the modeling predicts more visibility improvements (3.88 dv reduction) than required to meet the 2018 URP point (3.45 dv reduction). When looking at visibility projections across several Class I areas, it has been useful to present the 2018 visibility projections as a percentage of meeting the 2018 URP point; where 100% is meeting the point, greater than 100% surpassing the point (i.e., below the glidepath) and less than 100% means that less visibility improvement is achieved than needed to meet the 2018 URP point. For 2018 Base G CMAQ modeling at CACR, we achieve 112% of the visibility reduction needed to meet the 2018 URP point. Note that meeting the 2018 URP point is not a requirement of the RHR SIPs, rather it just serves as a benchmark to compare progress toward Natural Conditions in 2064 and is designed to help states in selecting their 2018 RPGs. As clearly stated in EPA guidance “The glidepath is not a presumptive target, and States may establish a RPG that provides for greater, lesser, or equivalent improvement as that described by the glidepath” (EPA, 2007b).

The 2018 Base G CMAQ visibility projections for the best 20 percent days and CACR is shown in Figure 4-3b. Recall the RHR goal for this visibility metric is no worsening of the visibility for the best 20 percent days. The Baseline Conditions for the best 20 percent days at CACR is 11.24 dv. The 2018 Base G projected visibility for the best 20 percent days is 10.35 dv, which represents a 0.89 dv visibility improvement for the best 20 percent days at CACR and demonstrating no worsening in visibility for the best 20 percent days.

Figure 4-3c displays “StackedBar Chart” plots of observed and model estimated extinction for each of the worst 20 percent days in 2002 and the 2002 Typical Base G CMAQ simulation and the average across the worst 20 percent days. This figure allows a comparison of how well the model is reproducing the observed extinction at CACR for the worst 20 percent days in 2002 and the breakdown of the PM components that are contributing to visibility impairment (more details on model performance were presented in Chapter 3). The 2002 worst 20 percent days at CACR are dominated by SO₄ days (yellow), although during the winter there are also three days dominated by NO₃ (Julian Days 80, 320 and 341). For most of the worst 20 percent days at CACR, the model reproduces the observed extinction reasonably well, although it does tend to understate SO₄ on a few days and overstate NO₃ on the four winter days. The observed average extinction across the 2002 worst 20 percent days at CACR is 150 Mm⁻¹, compared to a modeled value that is 23% lower (115 Mm⁻¹).

Figure 4-3d displays “Boxplots” of differences in modeled extinction for the 2002 worst 20 percent days between the 2018 Base G and 2002 Typical Base G CMAQ simulations. On most days SO₄ is the largest component of the extinction that is estimated to be reduced at CACR on the worst 20 percent days. The exception to this is for the winter NO₃ days where NO₃ is the largest component of extinction that is reduced. The modeling results are not used directly in the visibility projections, rather they are used to develop the PM-species specific RRFs. That is, an important attribute in Figures 4-3c and 4-3d is the relative changes in the modeled PM species averaged across the worst 20 percent days that are represented by the last bar in each figure and provide insight into the RRFs used in the visibility projections. These results are summarized in Table 4-3 below. Table 4-3 compares the average extinction across the 2002 worst 20 percent days at CACR from the measured IMPROVE data, the modeled values and the modeled change in extinction between the 2018 and 2002 emissions scenarios. Although the results in Table 4-3 are not RRFs (RRFs are based on ratios of concentrations not extinction) they do show how the RRFs may magnify or deflate the importance of a modeled PM species. For example, the model estimates that approximately 23% (26.66 Mm⁻¹) of the visibility extinction average across the worst 20 percent days is due to NO₃, whereas it is only 7% in the observed values (10.22 Mm⁻¹). So the modeled ~40% reduction in NO₃ between the 2018 and 2002 scenarios is applied to the smaller observed NO₃ value to obtain the 2018 projected NO₃ value making NO₃ a smaller portion of the 2018 projected visibility than the 2018 modeled visibility. On the other hand, the modeled SO₄ extinction is less than observed so that its importance in the 2018 projections is much greater than in the modeled 2018 SO₄ values.

Table 4-3. Observed and Modeled Extinction by Species Averaged Across the Worst 20 Percent Days in 2002 at CACR.

	2002 Average Observed W20% (Mm ⁻¹)	2002 Average Modeled W20% (Mm ⁻¹)	2018-2002 Reduction (Mm ⁻¹)	2018-2002 Reduction (%)
bSO4	109.50	67.90	-24.47	-36%
bNO3	10.22	26.66	-10.90	-41%
bOMC	19.65	16.68	-2.12	-13%
bEC	4.38	2.32	-0.67	-29%
bSOIL	1.43	1.04	+0.21	+20%
bCM	4.30	0.37	-0.01	-3%

Figure 4-3b. 2018 Visibility Projections and 2018 URP Glidepaths in Deciview for CACR, Arkansas and Best 20 Percent (B20%) days Using 2002/2018 Base G CMAQ 36 m Modeling Results.

Figure 4-3c. Comparison of Observed (left) and 2002 Base G Modeled (right) Daily Extinction for Caney Creek (CACR), Arkansas and Worst 20 Percent (W20%) days in 2002.

Figure 4-3d. Differences in Modeled 2002 and 2018 Base G CMAQ Results (2018-2002) Daily Extinction for Caney Creek (CACR), Arkansas and Worst 20 Percent (W20%) Days in 2002.

4.4.2 Summary 2018 Visibility Projections Across Class I Areas

Figure 4-4 displays a “DotPlot” of 2018 visibility projections using the 2002 Typical and 2018 base case Base G CMAQ 36 km modeling results. DotPlots present the 2018 visibility projections as a percentage of meeting the 2018 URP point. For example, at CACR the 2018 Base G modeling achieved 112% of the visibility reduction needed to meet the 2018 URP point so the dot under CACR is plotted at 112%. Class I areas’ with dots above 100% surpass the 2018 URP point (i.e., are below the glidepath), whereas Class I areas’ with dots that are under 100% fail to meet the 2018 URP point. Figure 4-4 summarizes the 2018 visibility projections using the EPA default “Regular RRF” and the two alternatives where CM is assumed to be natural (CM RRF=1) and both CM and Soil are assumed to be natural (CM&SOIL RRF=1). When CM or CM&SOIL are assumed to be natural that means that we assume the same CM or CM&SOIL occurs in the 2018 future-year as in the 2000-2004 Baseline Conditions. For the CENRAP sites, the EPA default and alternative projection, assuming CM alone or CM and Soil are natural, techniques produced similar results.

At the four eastern CENRAP Class I area sites close to the Mississippi River (CACR, UPBU, HEGL and MING), the 2018 visibility projections meet (HEGL) or surpass the 2018 URP point. Breton Island Class I area (BRET) comes up 6% short of meeting the 2018 URP point (i.e., 94% of the URP point). Wichita Mountains Class I area (WIMO) comes up approximately 40% short of the 2018 URP point. The two northern Class I areas (BOWA and VOYA) also come up about 40% short of meeting the 2018 URP point (i.e., achieve 69% and 53% of the visibility improvement needed to meet the 2018 URP point). The two Texas Class I areas only achieve

26% (BIBE) and 34% (GUMO) of the visibility improvement needed to meet the 2018 URP point for the worst 20 percent days. As discussed in more detail in Chapter 5, much of the difficulty for the Texas and some of the other CENRAP Class I areas in meeting the 2018 URP point is due to large contributions due to international transport, much of which (e.g., Mexico and global transport) is assumed to remain unchanged from 2002 to 2018.

Figure 4-4. 2018 Base G CMAQ Visibility Projections for CENRAP and Nearby Class I areas Using DotPlots that Express 2018 Visibility as a Percentage of Meeting the 2018 URP Point On the Deciview Linear Glidepath.

Figure 4-5 displays the model estimated absolute change in extinction (Mm^{-1}) averaged across the 2002 worst 20 percent days at Class I areas in and near the CENRAP region. The largest modeled reductions are in SO_4 extinction. Figure 4-6 displays the percent change in the projected PM extinction by PM species for each CENRAP and nearby Class I area average across the worst 20 percent days (i.e., the relative modeled change). The four CENRAP Class I areas that meet the 2018 URP point (CACR, UPBU, HEGL and MING) are characterized by large SO_4 , NO_3 and EC extinction reductions (30-40%) with small Soil increases. At the other CENRAP Class I areas, however, there are lower levels of SO_4 , NO_3 and EC extinction reductions and even some NO_3 increases (BIBE). At the non-CENRAP Class I areas, the two VISTAS Class I areas (MACA and SIPS) have large reductions in SO_4 extinction (~50%), whereas the WRAP Class I areas SO_4 extinction reductions are much smaller.

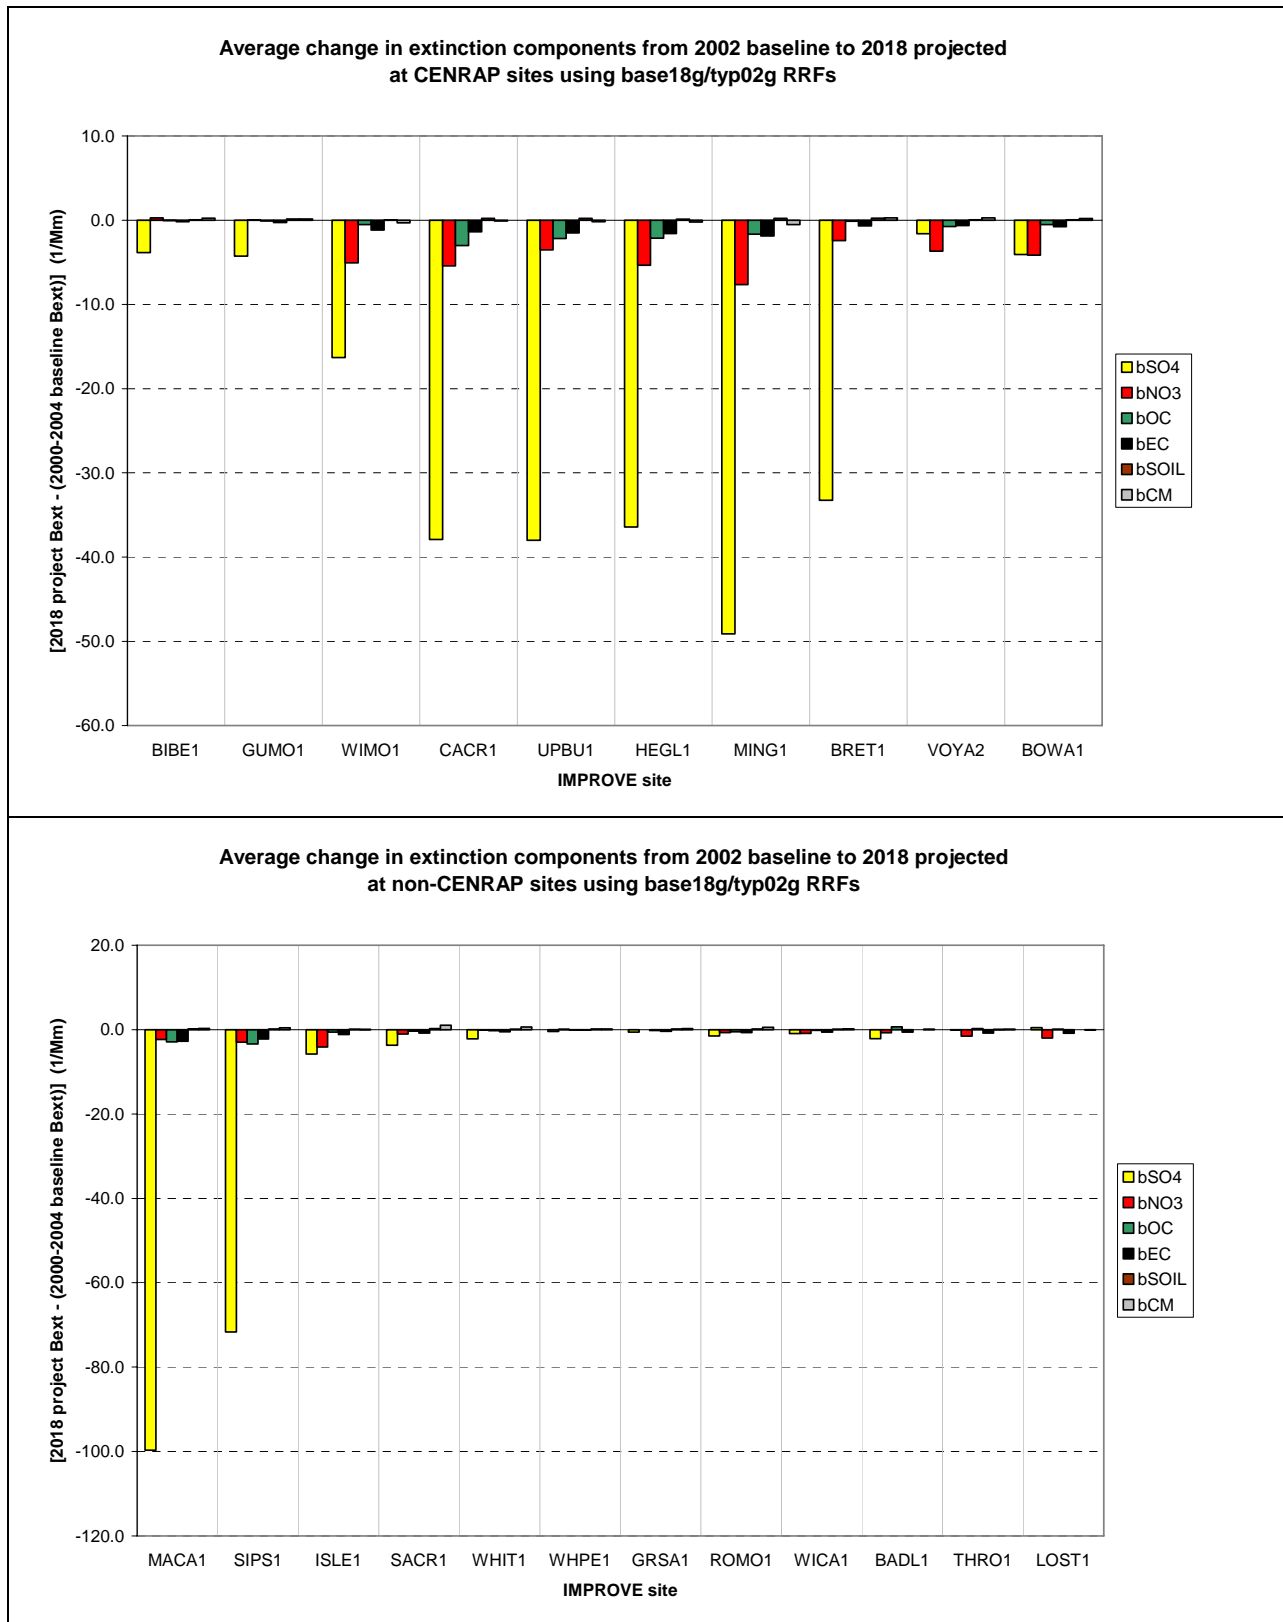

Figure 4-5. Absolute Model Estimated Changes in Extinction (Mm^{-1}) by PM Species for Class I Areas in the CENRAP region (top) and Near the CENRAP region (bottom).

Figure 4-6. Percent Change In Modeled Extinction by PM Species Averaged Across the 2002 Worst 20 Percent Days for Class I areas in the CENRAP region (top) and Near the CENRAP region (bottom).

4.5 2018 Visibility Projections for Base G C1 Control Scenario

The 2018 visibility projections based on the CMAQ simulations for the 2018 Base G C1 Control Strategy simulations are presented in this section. The C1 Control Strategy results in reductions mainly in SO₂ and NO_x emissions from point sources in the CENRAP states. Consequently, PM improvements are limited to mainly SO₄ and NO₃ concentration reductions in the CENRAP states. Figure 4-7 displays the differences in CMAQ-estimated annual average SO₄ and NO₃ concentrations between the 2018 Base G base case and the 2018 Base G C1 Control Strategy case; the differences in all other PM species (with the exception of NH₄) were negligible (see: <http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#base18gc1vsbase18g>). Annual average SO₄ concentration reductions of over a quarter of a µg/m³ are estimated to occur in northeast Texas, east Oklahoma, Missouri, northeast Arkansas and up into Iowa and Illinois. There are much lower reductions in NO₃ that cover a similar area.

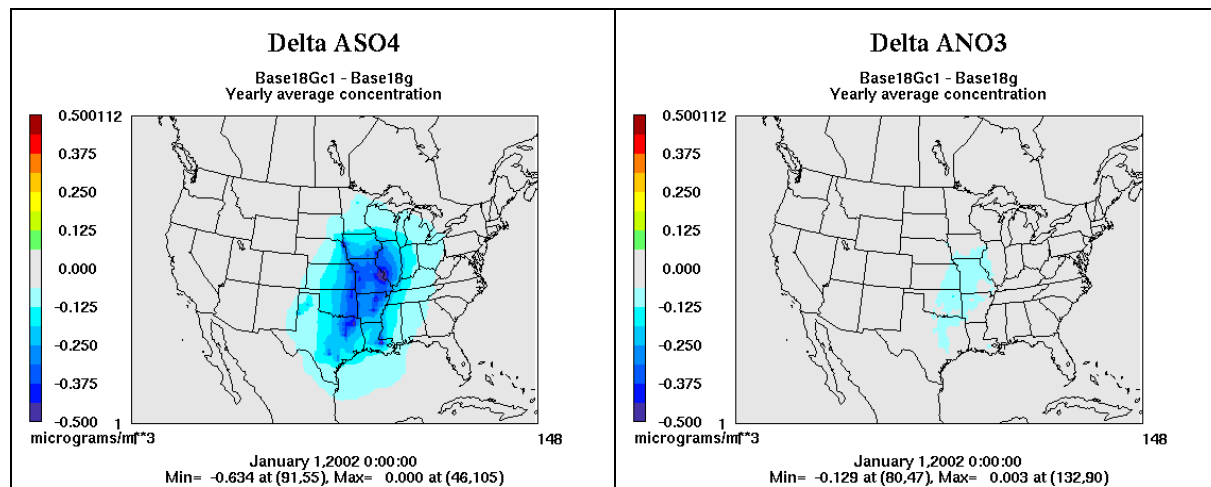

Figure 4-7. CMAQ-Estimated Reductions in Annual Average SO₄ (left) and NO₃ (right) Fine Particle Concentrations Between the 2018 Base G Base Case and 2018 Base G C1 Control Strategy Case.

Figure 4-8 displays the DotPlot comparisons of the 2018 visibility projections for 2018 Base G and 2018 Base G C1 Control Strategy emission scenarios. The additional controls in the C1 Control Strategy are projected to result in visibility improvements for the worst 20 percent days at Class I areas throughout and near the CENRAP region. Sites are closer to being on the glide path by 10 to 30 percent. For Breton Island this makes a difference of not meeting the 2018 URP point in 2018 Base G (94%) to surpassing the URP point in the C1 Control Strategy (106%).

Table 4-4 presents a tabular summary of the information presented in Figure 4-8, including the Baseline, 2018 URP point, and 2018 projected visibility for the Base G and C1 Control Strategy simulations.

Figure 4-8. 2018 Visibility Projections as a Percentage of Meeting the 2018 URP Point (i.e., DotPlot) for the 2018 Base G and 2018 Base G C1 Control Strategy Emission Scenarios.

Table 4-4. 2000-2004 Baseline, 2018 URP Point, and Projected 2018 Visibility and Percent of Meeting the 2018 URP Point for the 2018 Base G and 2018 C1 Control Strategy CMAQ Simulations.

5.0 ADDITIONAL SUPPORTING ANALYSIS

This Chapter presents additional supporting analysis to the modeled 2018 visibility projections provided in Chapter 4. This supporting analysis may be used by the states in their RHR SIPs, along with their factor analysis, to assist in setting their 2018 RPGs for the worst 20 percent days and best 20 percent days.

5.1 Comparison of CENRAP 2018 Visibility Projections with Other Groups

2018 visibility projections for CENRAP and nearby Class I area have also been performed by the other RPOs. Thus, it is useful to compare the CENRAP 2018 visibility projections with those from the other RPOs as a quality assurance (QA) check and to foster confidence in the CENRAP modeling results.

5.1.1 Comparison of CENRAP, VISTAS, MRPO and WRAP Visibility Projections

The CENRAP 2018 Base G visibility projections were compared to the following other RPO visibility projections:

- VISTAS 2018 visibility projections based on their CMAQ 12 km 2002 annual modeling results for the 2002 Base G and 2018 Base G2a emissions scenarios.
- MRPO 2018 visibility projections based on their CAMx 36 km 2002 annual modeling for the Run 4 Scenario 1a (R4S1a) emissions scenario.
- WRAP 2018 visibility results based on their Plan02b and Base18b CMAQ 36 km modeling of the 2002 calendar year.

Figure 5-1 displays a DotPlot comparison of the four RPO visibility projections expressed as a percentage of achieving the 2018 URP point at CENRAP and nearby Class I areas. For the four CENRAP Class I areas just west of the Mississippi River in Arkansas and Missouri (CACR, UPBU, HEGL and MING), 2018 visibility projections are available from the CENRAP, VISTAS and MRPO RPOs. At HEGL, the three RPOs 2018 visibility projections are in close agreement with each other (estimated to achieve 99%, 101% and 95% of the 2018 URP point). The CENRAP and VISTAS 2018 visibility projections are also very close at the other three Arkansas-Missouri CENRAP Class I areas: CACR (112% and 116%), UPBU (109% and 112%) and MING (118% and 114%). But the MRPO 2018 visibility projections are approximately 12 to 25 percentage points lower than the CENRAP and VISTAS projections at these three Class I areas, with values of 97% to 100%. The reasons why the MRPO 2018 visibility projections are less optimistic than CENRAP and VISTAS are unclear. However, the MRPO focused on visibility projections at their northern Class I areas and likely did not use the latest CENRAP emission estimates. In addition, the CENRAP 2018 visibility projections included BART controls on several sources in CENRAP states not included in the MRPO projections. Such BART controls are even more important in those states not covered by CAIR.

For the Breton Island (BRET) Class I area, 2018 visibility projections are available from CENRAP and VISTAS. CENRAP estimates that BRET will achieve 94% of the URP point and

VISTAS is slightly less optimistic with an 84% value. One potential contributor to this is that emissions from off-shore marine vessel emissions in the oil and gas production areas of the Gulf of Mexico are double counted in the VISTAS Base G modeling. As these emissions were assumed to remain unchanged between 2002 and 2018, the double counting of their emissions will result in stiffer RRFs than there should be and consequently less visibility benefits in 2018. This double counting also occurred in the CENRAP Base F modeling but was corrected in Base G. The double counting occurred because off-shore marine vessels were present in both the MMS off-shore oil/gas development inventory for the Gulf of Mexico and the VISTAS off-shore marine vessel inventory for the Pacific and Atlantic Oceans and the Gulf of Mexico. VISTAS intends to correct this double counting in their next round of modeling.

At the two northern Minnesota Class I areas (BOWA and VOYA), the MRPO 2018 visibility projections (93% and 92%) exhibit more visibility improvements than CENRAP's (69% and 53%). This is believed to be due to higher contributions to visibility impairment from Canada in the CENRAP modeling. Figure 5-2 displays the CENRAP 2002 Base F total SO₂ emissions and their differences with the 2018 Base F SO₂ emissions. The SO₂ emissions in Alberta Canada appear to be much higher and more wide spread when compared to the other provinces in Canada and emissions in the U.S. states. Also, there is a very large SO₂ source in northern Manitoba (> 10⁵ tons/year). The Alberta SO₂ emissions may be overstated in the CENRAP modeling, which would overstate the Canadian contribution to visibility impairment. The western boundary of the MRPO modeling domain was east of the Rocky Mountains so did not include Alberta. CENRAP confirmed that the Alberta emissions and the source in Manitoba were present in the emissions provided by Canada. Air parcels from Canada are generally associated with clean visibility conditions at the northern Minnesota Class I areas with the worst 20 percent days generally occurring under conditions with a southerly wind component. However, in 2002 some of the worst 20 percent days did occur with transport out of Canada. For example, Figure 5-3 displays back trajectories off of the VIEWS website for two of the worst 20 percent days at Voyageurs National Park (Julian Days 347 and 332). These back trajectories suggest that the potentially overstated emissions in Alberta would have an impact at VOYA during the worst 20 percent days in 2002.

At the VISTAS Mammoth Cave (MACA), Kentucky Class I area, VISTAS, CENRAP and the MRPO estimated that 2018 visibility for the worst 20 percent days will achieve, respectively, 122%, 123% and 102% of the 2018 URP point. The close agreement between the VISTAS (122%) and CENRAP (123%) 2018 visibility projections for MACA is encouraging. Why MRPO is 20 percentage points lower is unclear, but may be due to using earlier versions of the VISTAS and CENRAP emissions. The 2018 visibility projections at Sipsey (SIPS), Alabama estimated by VISTAS (127%) and CENRAP (130%) are also extremely close.

Both the CENRAP and WRAP 2018 visibility projections agree that the WRAP Class I areas fail to achieve the 2018 URP point by a wide margin, with values achieving only ~40% or less of the 2018 URP point. The CENRAP 2018 visibility projections agrees well with the WRAP values at Great Sands (GRSA), Colorado (18% vs. 15%), Badlands (BADL), South Dakota (24% vs. 31%), Theodore Roosevelt, North Dakota (15% vs. 11%) and Lostwood (LOST), Montana (11% vs. 14%). There is also reasonable agreement between CENRAP and WRAP 2018 visibility projections at Salt Creek (SACR), New Mexico (30% vs. 12%), Rocky Mountain (ROMO), Colorado (43% vs. 30%), and Wind Cave (WICA), South Dakota (24% vs. 6%). There are two WRAP Class I areas, White Mountains (WHIT) and Wheeler Peak (WEPE), where the WRAP

2018 visibility projections estimate that visibility will degrade for the worst 20 percent days (i.e., negative percent of achieving the 2018 URP point), whereas CENRAP estimates visibility improvements. The reasons for these differences are unclear.

Figure 5-1. DotPlot comparing the CENRAP, VISTAS, MRPO and WRAP 2018 visibility projections expressed as a percentage of achieving the 2018 URP goal.

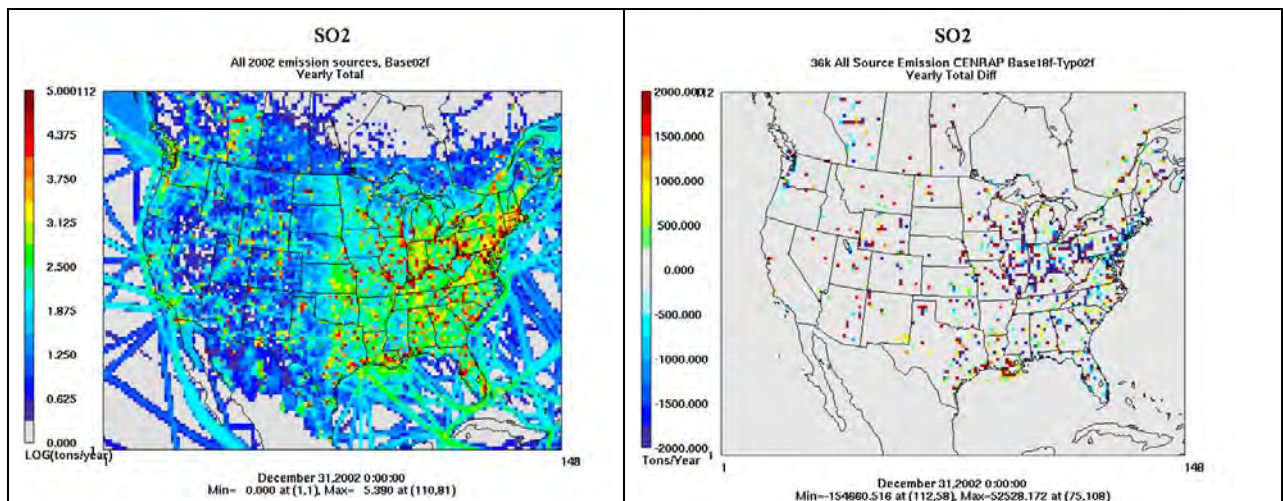

Figure 5-2. 2002 Base F SO2 emissions (left) as LOG10(tons/year) and differences in 2018 and 2002 Base F SO2 emissions (tons/year).

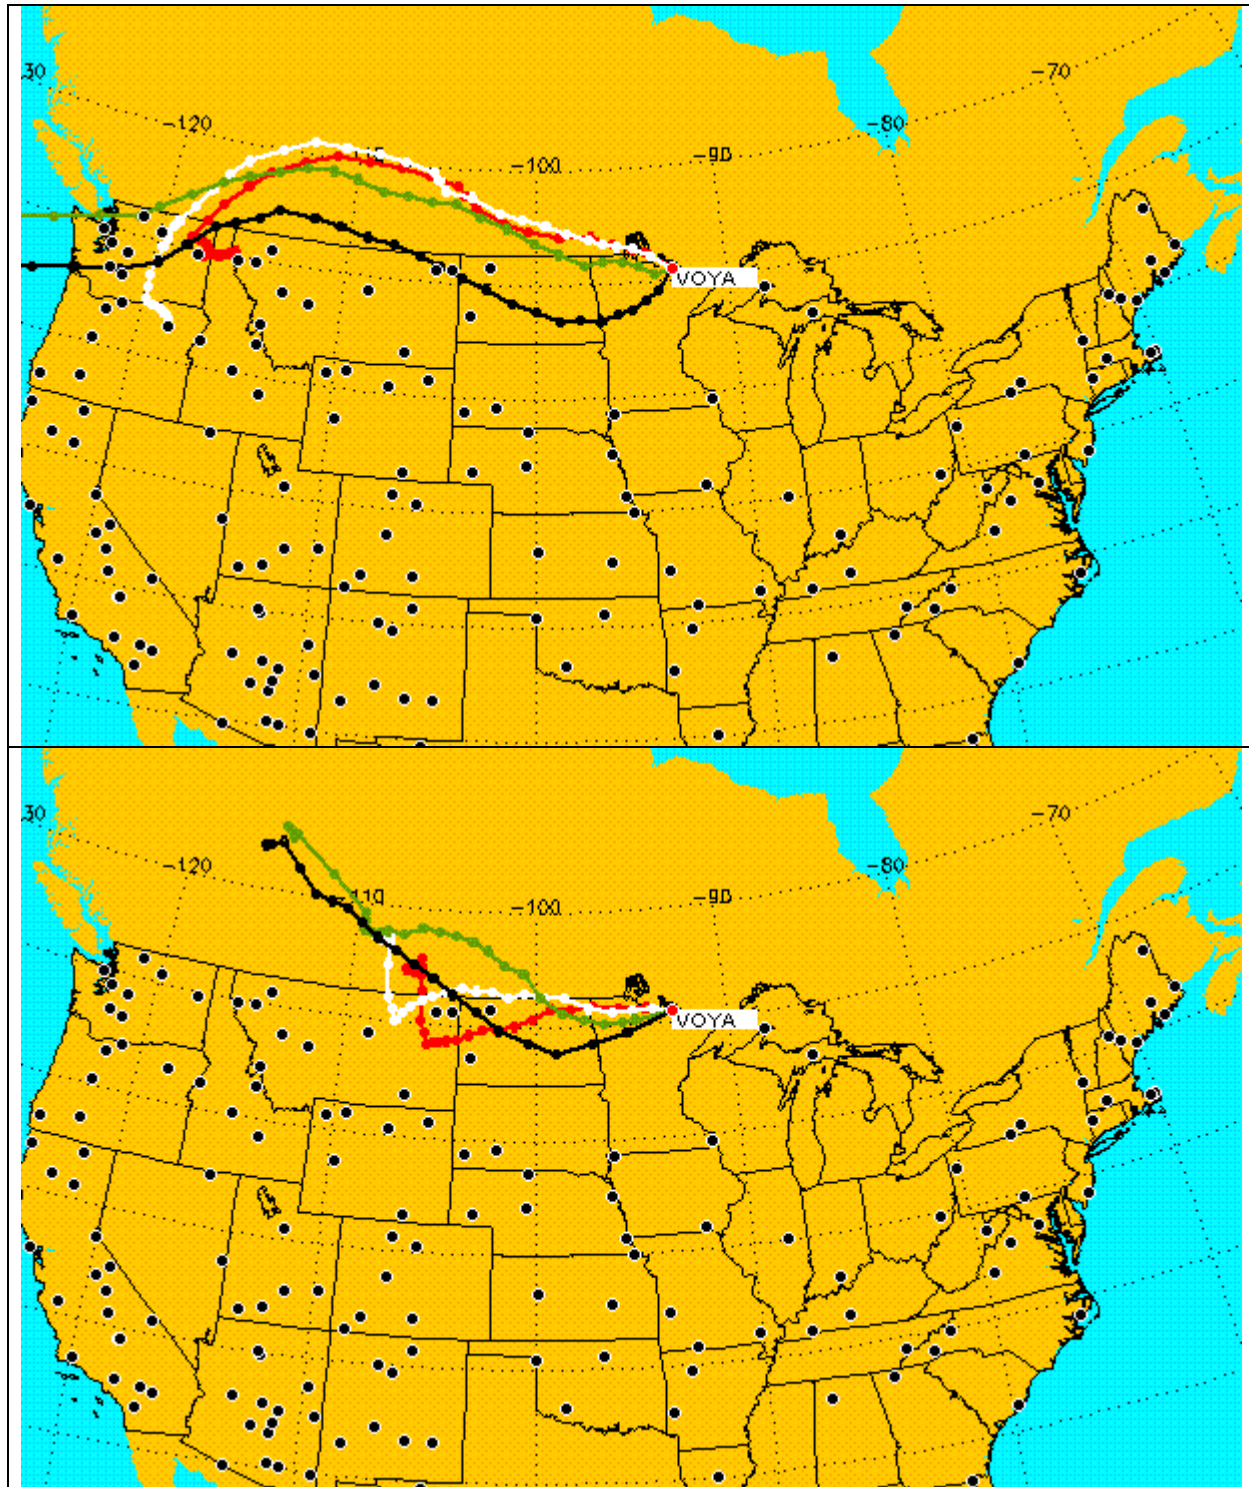

Figure 5-3. Exemplified back trajectories to Voyageurs National Park for two of the worst 20 percent days from 2002: December 13, 2002 (Julian Day 347) and November 28, 2002 (Julian Day 332).

5.2 Extinction and PM Species Specific Visibility Projections and Comparisons to 2018 URP Point

It is useful to examine 2018 visibility projections by PM species to determine how each PM component of visibility is changing as both a diagnostic analysis of the visibility projections as well as whether species that are associated more with anthropogenic emissions (e.g., SO₄ and NO₃) are being reduced substantially compared to those that are less influenced by anthropogenic emissions (e.g., Soil and CM). However, because deciview is the natural logarithm of total extinction, such comparisons can not be made using the deciview scale and must be made using extinction. The linear glidepath from which the 2018 URP points are derived are based on deciview, thus to examine corresponding glidepath using extinction the curvature associated with the logarithmic transformation of the linear deciview glidepath to extinction must be accounted for in the extinction glidepath.

5.2.1 Total Extinction Glidepaths

Figure 5-4 displays a total extinction based glidepath for Caney Creek that is based on the EPA default deciview linear glidepath counterpart shown in Figure 4-3a. That is, the deciview linear glidepath defined by the line connecting the 26.36 dv Baseline Conditions at 2004 to the 11.58 dv Natural Conditions in 2064. The glidepath points in 2008, 2018, 2028, etc. from the linear deciview glidepath (Figure 4-3a) are turned into extinction (Bext) [$Bext = 10 \exp(dv/10)$] to create the curved extinction glidepath that exactly match the linear deciview glidepath points. Note that the 2000-2004 Baseline using the curved extinction glidepath is slightly different than if you just converted the deciview baseline to extinction because the logarithm relationship is performed before the averaging, but they are extremely close. Using the extinction curved glidepath, the 2018 URP point is a reduction of the Baseline 145.10 Mm⁻¹ to 98.88 Mm⁻¹ (a 46.22 Mm⁻¹ reduction). The modeled 2018 visibility projection in extinction is 97.54 Mm⁻¹, a 47.56 Mm⁻¹ reduction, which achieves 103% of the reduction needed to achieve the 2018 URP point. Note that this compares with achieving 112% of the 2018 URP reduction point when using the deciview linear glidepath. The percent of achieving the 2018 URP point using the linear deciview and curved extinction glidepaths will rarely be the same due to the logarithmic relationship between the two visibility metrics and the fact that averaging within and across years in the deciview calculations occur after the logarithms have been applied. The greater the difference in extinction across the worst 20 percent days in a year and averaged across the years in the 2000-2004 Baseline and the greater number of years available from the 2000-2004 Baseline may result in greater differences in the 2018 URP points using the linear deciview and the curved extinction glidepaths.

Appendix F contains total extinction curved glidepaths for all the CENRAP Class I areas and Figure 5-5 contains a DotPlot that compares the percent of achieving the 2018 URP point at each CENRAP Class I area using the 2018 Base G modeling results and the linear deciview and curved extinction glidepaths. At most CENRAP Class I areas the ability of the 2018 modeling results to achieve the 2018 URP point is the same using either the deciview or extinction glidepaths. There are some differences at GUMO, BOWA and VOYA Class I areas which are due to these Class I areas having more complete data during the 2000-2004 Baseline period and therefore more years in the Baseline than other Class I areas as well as having variations in extinction across the worst 20 percent days and years (Appendix F). In any event, the closeness of the ability of the model to achieve the 2018 URP point using either the extinction or deciview

glidepath verifies the validity of the extinction based glidepaths and allows for the construction of PM species specific glidepaths in extinction to gain insight into how each component of extinction is being reduced to achieve a uniform rate of progress toward natural conditions in 2064.

Figure 5-4. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure 5-5. CMAQ 2018 Base G visibility projections and comparison of ability to achieve the 2018 URP point using the EPA default deciview and alternative total extinction Glidepaths.

5.2.2 PM Species specific Glidepaths

The VIEWS website (<http://vista.cira.colostate.edu/views/>) has posted PM species specific Natural Conditions based on the new IMPROVE equation. Using these PM species specific Natural Conditions and the curved extinction glidepaths we can evaluate how well visibility extinction achieves the 2018 URP point on a species-by-species basis. The PM species specific glidepaths are constructing starting with a Baseline at 2004 averaging the extinction for each PM species measured using the 2000-2004 IMPROVE observations and ending with the Natural Conditions in 2064 from the VIEWS website. Points in the glidepath for the years in between 2004 and 2064 are constructed based on the relative differences in the 2004 Baseline and 2064 Natural Conditions PM species extinction such that the total extinction due to all PM species at each interim year adds up to the same as the total extinction on the extinction-based glidepath (e.g., Figure 5-3). For example, for the CACR SO4 extinction glidepath the 2018 URP point is generated from the 2004 and 2064 SO4 extinction (BSO4) and the 2004, 2018 and 2064 total extinction (BTOT) as follows:

$$\begin{aligned}
 \text{BSO4}_{2018} &= \text{BSO4}_{2004} - [(\text{BSO4}_{2004} - \text{BSO4}_{2064}) / \\
 &\quad (\text{BTOT}_{2004} - \text{BTOT}_{2064})] \times (\text{BTOT}_{2004} - \text{BTOT}_{2018}) \\
 &= 87.05 - [(87.05 - 3.20) / (145.10 - 32.16)] \times (145.10 - 98.88) \\
 &= 52.73 \text{ Mm}^{-1}
 \end{aligned}$$

Note that the SO4 2018 URP point in Figure 5-5 and F-1b (52.77 Mm-1) does not exactly match the 52.73 Mm⁻¹ calculated due to round off error in the above calculation that only used numbers with precision to the nearest hundredth.

As there are larger differences between the Baseline and Natural PM species extinction for some species, then the rate of improvement to achieve a species specific 2018 URP point will vary across PM species. For example, current Baseline extinction values for Soil and CM tend to be closer to Natural Conditions than extinction due to SO4 and NO3. Consequently the rate of progress to achieve the 2018 URP point for Soil and CM will be less than for SO4 and NO3.

Appendix F contains the PM species specific glidepaths compares them to the modeled 2018 projections for all CENRAP Class I areas. The species specific results for the CACR Class I area in Figure F-1 are reproduced in Figure 5-6. The modeled rate of SO4 and NO3 extinction reduction is greater than the PM species specific glidepaths and both achieve the species specific 2018 URP point by achieving 111% and 104% of the reduction needed to achieve the 2018 URP point. The modeled rate of extinction improvement at CACR for EC and OC is less than the species specific glidepath achieving only 65% and 75% of the reduction needed to achieve the species specific 2018 URP point. The PM species specific glidepath for Soil is flat because the Baseline and Natural Conditions (1.12 Mm⁻¹) are the same. This does not mean that anthropogenic emissions of Soil do not contribute on worst 20 percent days at CACR. It just points to a mismatch between the current set of worst 20 percent days and those in 2064 under Natural Conditions. The worst 20 percent days in 2064 under Natural Conditions will be dominated by wind blown dust days when Soil and CM may be higher than during the current set of worst 20 percent days that are dominated by SO4, NO3 and OMC. Thus, the Soil and CM glidepaths tend to be flatter and in some cases may even have an upward trend for some Class I areas (see Appendix F). Soil is projected to increase at CACR in 2018 so does not achieve its species specific URP point. Little reduction in CM is also seen by 2018. As discussed

previously, this is due in part to incompatibilities between the measured Soil and CM values at the IMPROVE monitor and the modeled Soil and CM species. In the model, a large component of the Soil and CM in the inventory is due to paved and unpaved road dust. These emissions are directly related to Vehicles Miles Traveled (VMT). VMT is projected to increase in future-years resulting in increases in road dust emissions. At the IMPROVE monitor, much of the measured Soil and CM is likely due to local dust events that are not simulated by the model using a 36 km grid resolution. Thus, the 2018 projections for Soil and CM are likely applying modeled changes due to road dust to local Soil and CM concentrations that in reality are likely natural and should remain unchanged in the future year. This is why alternative 2018 modeled projection approaches have been developed that assume that CM and CM and Soil are natural so remain unchanged in the future-year (see Section 5.5).

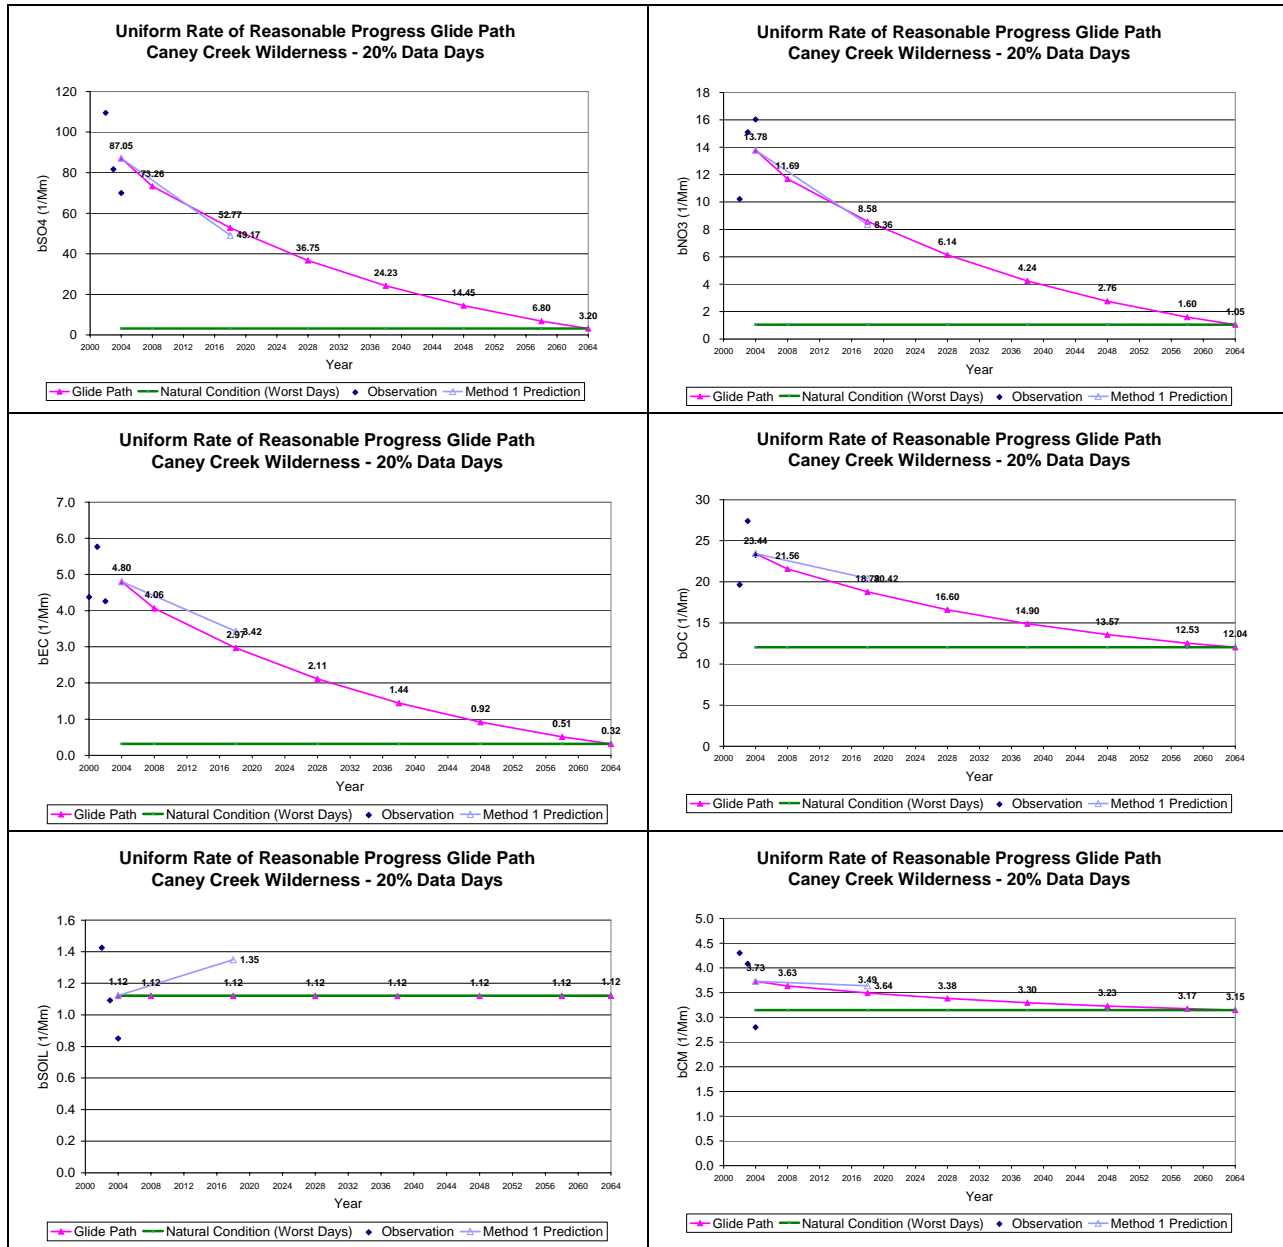

Figure 5-6. 2018 Visibility Projections and 2018 URP Glidepaths for SO4 (top left), NO3 (top right), EC (middle left), OMC (middle right), Soil (bottom left) and CM (bottom right) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20 Percent Days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure 5-7 displays a DotPlot that compares the 2018 projected total and PM species specific extinction with the 2018 URP points. These results show that SO4 is most frequently achieving its 2018 URP point at those Class I areas that achieve the deciview URP point. Reductions in NO3 and EC also sometimes achieve their species specific URP point.

There are some anomalies in the species specific projections and glidepaths that bear mention and point to areas where better estimates of emissions growth and Natural Conditions are needed. The increase in 2018 Soil projections is not an isolated incident at CACR and occurs at other CENRAP Class I areas. There are three CENRAP Class I areas that “achieve” the Soil specific 2018 URP point (HEGL, BOWA and VOYA). An examination of these glidepaths and visibility projections (Figures F-4f, F-5f and F-6f) reveals that the current Baseline Conditions Soil at these three Class I areas is actually less than the 2064 Natural Conditions so that the glidepath is an accent rather than reduction (Figures F-4g, F-5g and F-6g). In these three cases to “achieve” the 2018 URP point the modeling results must increase the projected Soil extinction, which is why these three Class I areas “achieve” their 2018 URP point for Soil. Clearly, the 2018 URP point for Soil is not very meaningful under these conditions. The current Baseline Conditions for OMC at BRET and BOWA is also less than the Natural Conditions resulting in anomalous glidepaths (Figure F-3e and F-4e).

Figure 5-7. Ability of total and species specific 2018 visibility projections to achieve 2018 URP points.

5.3 Alternative 2018 Visibility Projection Software

The CENRAP 2018 visibility projections were made using software developed by the CENRAP modeling team. PM concentrations in the 36 km grid cells containing each of the Class I area IMPROVE monitoring sites were extracted using the UCR Analysis Tool. These modeling data were then ported into Excel spreadsheets that also include the filled RHR IMPROVE database available from the VIEWS website along with the EPA default Natural Conditions (EPA, 2003b). Excel macros are then used to perform the visibility projections using the EPA default procedures described in Chapter 4 and alternative procedures described in this Chapter.

EPA is developing a Modeled Attainment Test Software (MATS) program that codifies the 8-hour ozone, PM_{2.5} and visibility projection procedures given in EPA's latest air quality modeling guidance (EPA, 2007a). The June 2007 release of the beta version of MATS is capable of performing 8-hour ozone and visibility projections; MATS is still under development for making PM_{2.5} projections. The June 2007 beta versions of MATS was applied to the CENRAP 2002 and 2018 Base G 36 km CMAQ results and the resultant 2018 visibility projections were compared with the CENRAP values using the EPA default projection approach (see Chapter 4) at CENRAP and nearby Class I areas. The projected 2018 visibility estimates using the CENRAP and EPA MATS software are shown in Table 5-1. The biggest differences in the two 2018 visibility projections are for the Boundary Waters (BOWA), Breton Island (BRET), and Mingo (MING) Class I areas where MATS produces no 2018 visibility projections. This is because there is insufficient capture of valid IMPROVE PM measurements within the 2000-2004 five-year baseline to generate three years of annual visibility estimates that is the minimum needed to develop the Baseline Conditions following EPA's guidance (EPA, 2003a). For the CENRAP projections, data filling was used to fill out the IMPROVE measurements with sufficient data so that Baseline Conditions could be calculated at these three Class I areas. At 14 of the remaining 17 Class I areas, the CENRAP and MATS 2018 visibility projections agree exactly to within a hundredth of a deciview. At the three sites that are different (BIBE, GUMO and ISLE) the difference is 0.01 dv, which is 0.06 percent or less. These differences are likely due to round off errors in the calculations and are not significant. These results verify the consistency with the CENRAP spreadsheet based and EPA MATS software for projecting future-year visibility estimates.

Table 5-1. Comparison of CENRAP and EPA MATS 2018 visibility projections at CENRAP and nearby Class I areas.

Site	2018 Visibility Projections		2000-2004 Baseline Conditions

5.4 PM Source Apportionment Modeling

The PM Source Apportionment Technology (PSAT) was used to obtain PM source apportionment by geographic regions and major source category for the CENRAP 2002 and 2018 Base E base case conditions. PSAT uses reactive tracers that operated in parallel to the CAMx host model using the same emissions, transport, chemical transformation and deposition rates as the host model to account for the contributions of user specified source regions and categories to PM concentrations throughout the modeling domain. Details on the formulation of the CAMx PSAT source apportionment can be found in the CAMx user’s guidance (ENVIRON, 2006; www.camx.com).

5.4.1 Definition of CENRAP 2002 and 2018 PM Source Apportionment Modeling

PSAT calculated PM source apportionment for user defined source groups. Source groups are usually defined by specifying a source region map of geographic regions where source contributions are desired and providing source categories as input so that source group would

consist of a geographic region plus source category (e.g., on-road mobile source emissions from Oklahoma). Although other source group configurations and even individual sources may be specified. For the CENRAP PSAT application, a source region map was used that divided up the modeling domain into 30 geographic source regions as shown in Figure 5-8. The 2002 and 2018 emissions inventories were divided into six source categories. The 30 geographic source regions consisted of CENRAP and nearby states, with Texas divided into 3 regions, remainder of the western and eastern States, Gulf of Mexico, Canada and Mexico. The original intent of the CENRAP PSAT analysis was to obtain separate contributions due to on-road mobile, non-road mobile, area, natural, EGU point and non-EGU point sources. However, the CAMx emissions for the PSAT runs were based on the CMAQ pre-merged 3-D emission files. Since all point sources were contained in a single CMAQ pre-merged emissions file, then the separate source apportionment modeling of EGU and non-EGU point sources was not possible. The six source categories that were separately tracked in the PSAT PM source apportionment modeling were:

- Elevated point sources;
- Low-level point sources (i.e., point source emissions emitted into layer 1 of the model);
- On-Road Mobile Sources;
- Non-Road Mobile Sources;
- Area Sources; and
- Natural Sources.

Natural Sources included biogenic VOC and NO_x emissions from the BEIS3 biogenic emissions model, emissions from wildfires and emissions from wind blown dust due to non-agriculture land use types.

PM source apportionment in PSAT is available for five families of PM tracers: (1) Sulfate; (2) Nitrate and Ammonium; (3) Secondary Organic Aerosols (SOA); (4) Primary PM; and (5) mercury. The CENRAP PSAT 2002 and 2018 applications used three of the PSAT families of tracers and did not use the SOA and mercury families. For SOA, the standard CAMx model output was used that partitions SOA into an anthropogenic (SOAA) and biogenic (SOAB) components.

The PSAT results were extracted at the CENRAP and nearby Class I areas and the contributions for the average of the worst 20 percent and best 20 percent days were processed. A PSAT Visualization Tool was developed that can be used by States, Tribes and others to generate displays of the contributions of source regions and categories to visibility impairment for the average of the worst 20 percent and best 20 percent days at each CENRAP and nearby Class I areas.

Figure 5-8. 30 source regions used in the CENRAP 2002 and 2018 CAMx PSAT PM source apportionment modeling.

5.4.2 CENRAP PSAT Visualization Tool

The PSAT Visualization Tool allows CENRAP States, Tribes and others to visualize the CENRAP 2002 and 2018 PSAT modeling results and identify which source regions, categories and PM species are contributing to visibility impairment at Class I areas for the average of the worst 20 percent and best 20 percent visibility days. The Visualization Tool is currently available on the CENRAP website (<http://www.cenrap.org>) under Projects. The Tool can generate bar charts of source contributions at Class I areas. It can be run in a receptor oriented mode where it identifies the contributions of PM species and source regions and categories to visibility impairment on the worst and best 20 percent days. It can also be run in a source oriented mode to examine an individual source region’s (State’s) contribution to visibility impairment at downwind Class I areas on the worst and best 20% days. The original IMPROVE equation is used to convert the PM species concentrations to extinction.

There are 14 air quality analysis metrics in the Tool:

W20% Modeled Bext: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area estimated by the model averaged across the worst 20 percent days in 2002.

W20% Projected Bext: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area projected by the model averaged across the worst 20 percent days in the 2000-2004 Baseline.

W20% Modeled USAnthro: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area for just U.S. anthropogenic emission source categories estimated by the model averaged across the worst 20 percent days in 2002.

W20% Projected USAnthro: The source region, source category and PM species contributions to the extinction (Bext) at a Class I area for just U.S. anthropogenic emission source categories projected by the model averaged across the worst 20 percent days in the 2000-2004 Baseline.

Emissions: Emissions by source region, source category and PM precursor. Precursors include SO_x, NO_x, primary organic aerosol (POA), primary elemental carbon (PEC) other primary fine particulate (FCRS+FPRM) and coarse mass (CCRS+CPRM). Emissions for four days have been extracted and implemented in the Tool.

Control Effectiveness: Control effectiveness is defined as the PM contribution divided by the emissions of the primary precursor. For example the SO₄ contribution divided by the SO₂ emissions.

Visualization Tool results are available for visibility contributions on both an absolute (Mm^{-1}) and percentage basis. When looking at contributions at a given Class I area, contributions can be examined in terms of PM species, source regions and/or source categories. Results are available for both the current year (2002 modeled or 2000-2004 projected) and future year (2018). The “2002 W20% Project Bext” metric applies the 2002 PSAT modeled source apportionment to the observed 2000-2004 Baseline extinction keeping the relative contributions of source groups to each PM species (e.g., SO₄, NO₃, etc.) the same averaged across the 2002 worst 20 percent days but scaling their magnitudes up or down based on the ratio of the 2000-2004 Baseline to the 2002 modeling results. Similarly, the “2018 W20% Projected” metric uses the relative contributions of the 2018 PSAT results from each source group and scales them according to the differences in the 2018 projected PM species to the 2018 modeled PM species for the average of the worst 20 percent days. The US Anthropogenic metrics just include source groups associated with U.S. man-made emissions (i.e., non-Natural source categories from states and Gulf of Mexico source regions) so excludes contributions from Canada and Mexico, Boundary Conditions, SOA from biogenic sources and the natural source category (biogenic NO_x, wildfires and wind blown dust).

5.4.3 Source Contributions to Visibility Impairment at Class I Areas

Appendix E displays example contributions of PM species, source regions and source categories to visibility impairment for the worst and best 20 percent days at the CENRAP Class I areas. Some of the results from Figure E-1 for the CACR Class I area are reproduced in Figures 5-9, 5-10 and 5-11 below.

5.4.3.1 Caney Creek (CACR) Arkansas

2002 visibility impairment for the worst 20 percent days at CACR is primarily due to SO₄ from elevated point sources that contributes over half (66.3 Mm⁻¹) of the total extinction of 118.8 Mm⁻¹ (Figure E-1a and 5-8 left). By 2018, the total extinction at CACR for the worst 20 percent days is reduced by approximately one third (38.5 Mm⁻¹) which is primarily due to reductions in SO₄ extinction from elevated point sources (from 66.3 to 37.3 Mm⁻¹) as well as reductions in visibility impairment from on-road and non-road mobile sources. Even with such large reductions in SO₄ from point sources in 2018, extinction due to elevated point sources is still the highest contributor to visibility impairment on the worst 20 percent days contributing over half (41.8 Mm⁻¹) of the total extinction in 2018 of 80.3 Mm⁻¹, with area sources the next most important source category contributing 16.0 Mm⁻¹ (~20%).

The geographic source apportionment for the worst 20 percent says at CACR is shown in Figures 5-10, E-1c and E-1d. Elevated point sources from the eastern source region is the largest contributor in 2002 contributing almost 18 Mm⁻¹ that is reduced by over a factor of three in 2018 to approximately 5 Mm⁻¹. By 2018, Arkansas is the largest contributor to extinction at CACR for the 20 percent worst days followed by East Texas, the large Eastern U.S. region and then SOA due to biogenic sources. Figures E-1e ranks the source group contributions to extinction on the worst 20 percent days at CACR with Elevated Point Sources from East Texas being the highest contributor to total extinction, similar results are seen when examining extinction at CACR for the worst 20 percent days due to just SO₄ and NO₃ (Figure E-1f).

For the best 20 percent days at CACR (Figures 5-11, E-1g-j), SO₄ is still a major contributor but no where near as dominate as seen for the worst 20 percent days, but elevated point is still the largest contributing source category Local contributions from within Arkansas contribute the most to the average of extinction across the best 20 percent days at CACR.

Figure 5-9. PSAT source category by PM species contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm⁻¹) for the worst 20 percent visibility days at Caney Creek (CACR), Arkansas.

Figure 5-10. PSAT source region by source category contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm^{-1}) for the worst 20 percent visibility days at Caney Creek (CACR), Arkansas.

Figure 5-11. PSAT source category by PM species contributions to the average 2000-2004 Baseline and 2018 projected extinction (Mm^{-1}) for the best 20 percent visibility days at Caney Creek (CACR), Arkansas.

5.4.3.2 Upper Buffalo (UPBU) Arkansas

The contributions to extinction on the worst 20 percent days at UPBU (Figure E-2) is similar to CACR only with less contributions from East Texas and more from Missouri, Illinois and Indiana. By 2018, the top five highest contributing source groups to the average extinction on the worst 20 percent days are as follows: Arkansas Elevated Point; SOA from biogenics; Boundary Conditions, East Elevated Points, and Illinois Elevated Points (Figure E-2e). On the best 20 percent days at UPBU visibility impairment is primarily due to Arkansas and adjacent states Oklahoma, Missouri, and Kansas).

5.4.3.3 Breton Island (BRET) Missouri

Visibility impairment for the worst 20 percent days at Breton Island is primarily (69%) due to elevated point sources that contribute 77.7 Mm^{-1} out of a total of 122.2 Mm^{-1} (Figure E-3a). Although the contribution of elevated point sources is reduced substantially by 2018, they still contribute over half of the total extinction (101.1 Mm^{-1}) on the worst 20 percent days at BRET (Figure E-3b). The top five contributing source groups to 2018 visibility impairment at BRET for the worst 20 percent days are: Louisiana Elevated Point Sources; Boundary Conditions; East Elevated Point Sources; Gulf of Mexico Area Sources and Louisiana Area Sources. Gulf of Mexico Area sources includes off shore shipping and oil and gas development emissions; note that for the PSAT simulation the off-shore marine shipping emissions were double counted which was corrected in the Base G emission scenarios used in the 2018 visibility projections discussed in Chapter 4.

5.4.3.4 Boundary Waters (BOWA) Minnesota

As seen for the other Class I areas, elevated point sources contribute the largest amount (47%) to visibility impairment at BOWA for the worst 20 percent days in 2002 (Figure E-4a). However, unlike many of the other Class I areas, there is little reductions (~10%) in the elevated point source contributions going from 2002 (29.0 Mm^{-1}) to 2018 (26.2 Mm^{-1}) (Figures E-4a and E-4b). This is because there is a slight increase in the contributions of elevated point sources in Minnesota from 2002 to 2018 (Figures E-4c and E-4d) that is the highest contributing source group (Figure E-4e). Note that the 2018 emission scenario includes growth and CAIR controls but no BART controls. For the best 20 percent days, the largest contributing source group by far is Boundary Conditions (i.e., global transport) followed by Minnesota and Canada (Figures E-4g-j).

5.4.3.5 Voyageurs (VOYA) Minnesota

Results for VOYA are similar to BOWA with Minnesota, Canada and Boundary Conditions contributing the most to visibility impairment on the worst and best 20 percent days (Figure E-5).

5.4.3.6 Hercules Glade (HEGL) Missouri

Elevated point sources contribute over half to the total extinction for the worst 20 percent days at HEGL in 2002 (Figures E-6a and E-6b). Going from 2002 to 2018 the contributions due to elevated point sources, on-road mobile and non-road mobile are reduced substantially, but the contributions due to the other sources remain unchanged. The largest source group contributing to visibility impairment on the worst 20 percent days is area sources from Missouri in both 2002 and 2018 (Figures E-6c and E-6d). Since area emissions are not reduced much between 2002 and 2018 and Missouri elevated point sources are mostly unchanged because the IPM model assumed Missouri CAIR sources would buy credits, then the Missouri contributions is only reduced a little going from 2002 to 2018 (from $\sim 18 \text{ Mm}^{-1}$ to $\sim 16 \text{ Mm}^{-1}$). However, the contributions due to the Eastern U.S., Illinois and Indiana are reduced substantially. Missouri is by far the largest contribution to visibility impairment at UPBU on the best 20 percent days as

well with area sources from Missouri being the largest source category (Figures E-6h through E-6j).

5.4.3.7 Mingo (MING) Missouri

The substantial improvements in visibility impairment at MING for the worst 20 percent days from 2002 (141 Mm^{-1}) to 2018 (96 Mm^{-1}) is primarily due to reductions in SO_4 from non-Missouri elevated point sources (Figures E-7a through E-7d). Even so, with the exception of the top contributing Missouri area sources the largest contributing source groups to 2018 visibility impairment for the worst 20 percent days are still elevated point sources from several CAIR states (Illinois, Indiana, Missouri, East; Figure E-7e). Missouri is the largest contributor to visibility on the best 20 percent days followed by Boundary Conditions and Illinois (Figure E-7i-j).

5.4.3.8 Wichita Mountains (WIMO) Oklahoma

Elevated point sources are the largest contributors to visibility impairment on the worst 20 percent days at WIMO in both 2002 and 2018 (Figures E-8a and E-8b). East Texas followed closely by Oklahoma are the largest contributing source regions in 2002, but by 2018 the reverse is true (Figures E-8c and E-8d). By 2018 the largest contributing source group to visibility impairment on the worst 20 percent days at WIMO is global transport (i.e., boundary conditions) followed by Oklahoma Area Sources and East Texas Elevated Point sources (Figure E-8e). Oklahoma Area Sources is the largest contributor to visibility impairment on the best 20 percent days at WIMO (Figures E-8g-j).

5.4.3.9 Big Bend (BIBE) Texas

Elevated point sources ($\sim 17 \text{ Mm}^{-1}$) followed by Boundary Conditions ($\sim 12 \text{ Mm}^{-1}$) are the largest contributions to total extinction (46 Mm^{-1}) on the worst 20 percent days at BIBE in 2002 (Figure E-9a). In 2018 there is very little ($\sim 2 \text{ Mm}^{-1}$) reduction in the contributions of elevated point sources and no reductions in global transport resulting in little reductions ($\sim 7\%$) in visibility impairment on the worst 20 percent days from 2002 (46 Mm^{-1}) to 2018 (43 Mm^{-1}). This is due to the extremely large contributions of emissions from Mexico in both 2002 (Figure E-9c) and 2018 (Figure E-9d). In fact, the four highest contributing source groups to visibility impairment at BIBE for the worst 20 percent days are assumed to be unchanged from 2002 to 2018: Boundary Conditions, Mexico Elevated Points, West Texas Natural and Mexico Natural (Figure E-9e). For the best 20 percent days at BIBE, West Texas, Mexico and Boundary Conditions are the highest three contributors to visibility impairment (Figures E-9g-j).

5.4.3.10 Guadalupe Mountains (GUMO) Texas

The large contribution of CM to visibility impairment at GUMO is clearly evident in the source apportionment modeling results (Figures E-10a-b). These sources are about evenly divided in the modeling between natural sources and area sources. Since these source categories are not reduced in the future year then there is little reduction in extinction from 2002 to 2018 (50 to 45

Mm^{-1}) and what reductions there are come from Elevated Point Sources. Sources in West Texas, Mexico, Boundary Conditions and New Mexico are the largest contributing source regions for both the worst 20 percent days (Figure E-10c-e) and best 20 percent days (Figures E-10g-j).

5.5 Alternative Visibility Projection Procedures

In this section we analyze several alternative visibility projection procedures from the EPA's default approach (EPA, 2007a) used in Chapter 4.

5.5.1 Treatment of Coarse Mass and Soil

As noted previously, much of the coarse mass (CM) and, to a lesser extent, Soil measured at the IMPROVE monitor is likely due to local wind blown dust that is natural in origin and not captured by the model. Consequently, even using the modeling results in a relative sense with the RRFs may not be appropriate for projecting CM and Soil. If CM and Soil are in fact local impacts due to wind blown dust from natural lands, then it would be appropriate to assume they are natural and remain unchanged from the 2000-2004 Baseline to 2018. This is probably certainly appropriate for CM because CM is primarily due to fugitive dust and it has a very short transport distance that is subgrid-scale to the model. In fact the model evaluation discussed in Chapter 3 and Appendix C clearly shows a large underprediction bias for CM that is likely due to local fugitive dust impacts at the IMPROVE monitor. For Soil this is less clear as fine particles can be transported over longer distances and is produced by anthropogenic sources, such as combustion and road dust, as well as natural sources. We initially performed two CM and Soil sensitivity tests, the first assumed CM was all natural so remains unchanged from the 2000-2004 Baseline to 2018 (i.e., set the RRF for CM equal to 1.0). The second sensitivity test assumed both CM and Soil were natural so set RRFs for both of them to 1.0. A comment from an FLM noted that we know some of the Soil is likely anthropogenic in origin. So it was suggested to subtract the 2002 base case modeled Soil from the observed values for the 2002 worst 20 percent days and assume that the remainder (if any) was natural so hold the rest of the Soil constant in 2018 and add to the 2018 modeled Soil values.

The results of the CM and Soil visibility projection sensitivity analysis are shown in the DotPlot in Figure 5-12. The CM and Soil visibility projection sensitivity analysis has little effect on the 2018 visibility projections at the CENRAP Class I areas. Even GUMO, which has a large CM and Soil component, shows very little sensitivity. This is probably because the CM at GUMO is likely dominated by wind blown dust that was assumed constant from 2002 to 2018 so the RRF calculated using the default EPA method is near 1.0 anyway. Some larger sensitivity is seen at several WRAP Class I areas. It is encouraging that CENRAP 2018 visibility projections are not sensitive to the CM and Soil components of the modeling which are highly uncertain.

Figure 5-12. Sensitivity of 2018 visibility projections to various methods that assume all CM, all CM and Soil and all CM and part of the Soil is natural.

5.6 Alternative Model

The CAMx model was also run for a 2002 and 2018 base case scenarios with earlier versions of the CENRAP emissions (Base E modified to eliminate double counting of some area fire emissions) than the final CMAQ 2002 Base G modeling. The CAMx 2002 and 2018 output was processed the same way that the CMAQ results were to generate 2018 visibility projections at the CENRAP and nearby Class I areas that were compared with the 2018 URP point. Figure 5-13 summarizes the CAMx 2018 visibility projections using the new IMPROVE algorithm (NIA) in a DotPlot and compares them with the CMAQ 2018 Base G results (from Figure 5-12). The CMAQ and CAMx 2018 visibility projections are remarkably similar. The four Arkansas and Missouri Class I areas are projected to achieve the 2018 URP point by almost the exact same amount by the two models. The two Texas Class I areas are projected to come up short of achieving the 2018 URP point by the same amount by the two models. The largest differences are seen at BRET, and to a lesser extent BOWA and VOYA. At BRET the CAMx 2018 visibility projections are much less optimistic (< 80%) in achieving the 2018 URP point than CMAQ (> 90%). And CMAQ is slightly less optimistic than CAMx in achieving the 2018 URP point for the two northern Minnesota Class I areas. The reasons for these differences are unclear but could be partially due to the emissions updates in the final CMAQ Base G run that included eliminating the double counting of off-shore marine emissions in the Gulf of Mexico that was present in the CAMx simulation, which makes it more difficult to get visibility improvements at BRET since it is influenced by sources in the Gulf. Corrections to stack parameters for Canadian point sources were also made for the final Base G. The general close agreement of the CAMx 2018 visibility projections to the final CMAQ values is encouraging and good QA check.

Figure 5-13. Comparison of CAMx 2018 visibility projections with 2018 URP points for CENRAP and nearby Class I areas.

5.7 Effects of International Transport on 2018 Visibility Projections

As seen in the PM source apportionment modeling discussed in Section 5.4, there is significant contributions of international sources to visibility impairment at many CENRAP Class I areas for the worst 20 percent days. With the exception of Canada, where we used a year 2000 inventory for the 2002 base case modeling and a 2020 inventory for the 2018 inventory, international sources were assumed to be constant between 2002 and 2018. Thus, Class I areas that are heavily impacted by contributions of international transport will have a difficult time achieving the 2018 URP point since international sources are assumed to remain constant. The CAMx PSAT runs discussed previously provide a framework for quantitatively assessing the contributions of international transport to the visibility projections and whether reasonable progress toward natural conditions is being achieved in the 2018 modeling.

There are several source regions (Figure 5-8) and source categories in the PSAT modeling that include international sources:

- Mexico Anthropogenic Sources (assumed all international);
- Canada Anthropogenic Sources (assumed all international);
- Gulf of Mexico (assumed all U.S. sources);
- Pacific and Atlanta Ocean (assumed all U.S. sources); and
- Boundary Conditions (assumed half international and half natural sources).

Although it can be argued that Mexico and Canada are not truly international due to the presence of numerous U.S. corporations in Mexico along with free trade among the two countries, states and federal government have no jurisdiction to regulate industry in these two countries so they are considered international in these calculations. The Gulf of Mexico includes off-shore oil and gas production facilities, support vessels and aircraft and off-shore marine shipping. Given that emissions from the oil and gas production can be regulated by the U.S., then the Gulf of Mexico is not considered an international source. Emissions from off-shore shipping in the Pacific and Atlantic Oceans are also currently not regulated by the U.S. government. However, there are current efforts to apply some regulations to these emissions so for these calculations they were not assumed to be international sources. Finally, the Boundary Conditions (BCs) for the CENRAP modeling were generated from a 2002 simulation of the GEOS-CHEM global chemistry model and held constant in 2018. These BCs would include contributions from international sources as well as natural sources, so need to be split. For the sensitivity calculations discussed below we assumed that the BCs were half due to natural and half due to international sources. This results in international sources being defined as follows:

$$\text{International Contribution} = \text{Mexico Anthro} + \text{Canada Anthro} + \frac{1}{2} \text{BCs}$$

Two methods were examined to see what the effects of international sources on 2018 visibility projections and a Class I areas ability to achieve the 2018 URP point:

Elimination of International Contributions to 2018 Visibility Projections: In this method the contribution of international emissions is taken out of the 2018 visibility projections and examined to see whether the new visibility projection achieves the URP point. If so, then international sources are hindering a Class I area in achieving the 2018 URP point, which suggests that the 2018 URP point is not a reasonable value for an RPG.

Visibility Projections and Glidepaths Based on Controllable Visibility Impairment: The second method would look at the visibility projections for just the U.S. controllable portion of the visibility impairment. The glidepath end point in 2064 would be to eliminate the U.S. man-made contributions to visibility impairment on the worst 20 percent days.

Note that this analysis is performed solely for providing states and others additional information on which Class I areas the modeling suggest are unduly influenced by International Transport.

5.7.1 Elimination of International Contributions to 2018 Visibility Projections

This method was also discussed in a recent technical brief prepared by the Electric Power Research Institute (EPRI), only in EPRI's analysis they used results from a global chemistry model and VISTAS CMAQ runs with no global anthropogenic emissions (EPRI, 2007). Thus, before discussing our results of this analysis using PSAT, we discuss EPRI's analysis.

5.7.1.1 EPRI's Analysis of Effects of International Contributions

EPRI funded Harvard University to perform annual simulations of the GEOS-Chem global chemistry model (<http://www-as.harvard.edu/chemistry/trop/geos/>) for annual simulations with and without non-U.S. anthropogenic emissions to determine the contributions of international transport to PM and visibility. The EPRI Harvard GEOS-Chem simulations were performed for 2001. Figure 5-14 and 5-15 compare the annual average ammonium sulfate, ammonium nitrate organic mass carbon (OMC, also called OCM) and elemental carbon (EC) due to the GEOS-Chem global modeling and the CAMx PSAT source apportionment modeling. The similarity of the results for ammonium sulfate is remarkable (Figure 5-14). Both methods estimate that the annual average ammonium sulfate contribution due to international sources ranges from 0.4 to 1.0 $\mu\text{g}/\text{m}^3$ across the Class I areas. There is less agreement between the two methods for ammonium nitrate due in part to a CAMx overestimation issue that is likely due in part to how ammonia emissions were classified as being anthropogenic or not in the no U.S. anthropogenic emissions simulations (Figure 5-15). Better agreement is seen between the two methods international contributions of OMC and EC, although CAMx estimates higher contributions than GEOS-Chem.

Figure 5-14. Comparison of EPRI Harvard GEOS-Chem global chemistry (top) and CENRAP PSAT (bottom) international source contributions to ammonium sulfate at Class I areas.

Figure 5-15. Comparison of EPRI Harvard GEOS-Chem global chemistry (top) and CENRAP PSAT (bottom) international source contributions to ammonium nitrate, organic carbon mass (OCM or OMC) and elemental carbon (EC) at Class I areas.

The EPRI technical brief used the VISTAS CMAQ runs to adjust the modeled 2018 visibility projections to eliminate the effect of international transport and compared them to the 2018 URP point. For the Boundary Waters, Voyageurs, Isle Royal and Seney Class I areas the standard 2018 visibility projections did not achieve the 2018 URP point. However, when the effect of transboundary pollutions was removed the 2018 URP point was essentially achieved or more than achieved at all four Class I areas.

5.7.1.2 CENRAP Results From Elimination International Transport

Because the elimination of the international sources from the 2018 visibility projections results in a portion of the total light extinction, then these comparisons with the 2018 URP points were done using extinction glidepaths and projections rather than deciview. In Section 5.2.1 we demonstrated that the level of achieving the 2018 URP point was almost identical at CENRAP Class I areas whether the linear deciview or curved extinction glidepaths were used. The PSAT source apportionment was used to determine the contribution to the projected extinction in 2018 due to international sources. As noted above, international sources were assumed to be due to anthropogenic emissions in Mexico and Canada and half of the Boundary Conditions.

Figure 5-16 shows the standard CAMx extinction glidepaths and 2018 visibility projections and the 2018 visibility projections when the contributions of international sources is eliminated. CACR, which achieved the 2018 URP point by 104%, achieves it by even more when international sources are eliminated (117%). UPBU that barely achieved the 2018 URP point by 102% achieves it by 116% without international emissions.

BRET comes up short of achieving the 2018 URP point when international emission are included (76%) as well as when they are eliminated (92%), although it is much closer (recall contributions of Gulf of Mexico to visibility impairment at BRET that is assumed in this analysis to be of U.S. origin). Eliminating international transport emissions makes of difference of meeting the 2018 URP point without them (120%) to not meeting it with them (64%) at BOWA. Similarly at VOYA the standard 2018 visibility projections do not achieve the 2018 URP point (54%), whereas it is achieved by a far margin when international sources are eliminated (132%).

HEGL comes up short achieving the 2018 URP point when international sources are included (95%), but achieves it when they are eliminated (107%). Recall the standard CAMx deciview visibility projections barely achieved the URP point even when international emissions are included (Figure 5-13). MING achieves the 2018 URP point with (106%) and without (116%) international sources. WIMO does not achieve the 2018 URP point when international contributions are eliminated.

International sources have by far the largest effect at BIBE. Whereas the standard 2018 visibility projections only achieved 27% of the reductions needed to achieve the 2018 URP point, elimination of the international source contributions achieves 172% of the reduction needed. GUMO comes up short in achieving the 2018 URP point when international sources are included (31%), but achieves it when they are not (107%).

Figure 5-16. Elimination of international sources from 2018 visibility projections and comparison with 2018 URP point at CENRAP Class I areas.

5.7.2 Glidepaths Based on Controllable Extinction

Another alternative glidepath that was examined using the CAMx PSAT source apportionment results was based on the U.S. anthropogenic emissions contributions to visibility impairment on the worst 20 percent days at the CENRAP Class I areas. The RHR strives to achieve “natural visibility conditions” by 2064 and defines natural conditions as conditions that would exist “in the absence of human caused impairment”. As shown above, anthropogenic emissions from international sources contribute significantly to visibility impairment at many of the CENRAP Class I areas making the RHR objective not practical if contributions from such sources are not reduced. Given that states and EPA have no jurisdiction over international sources, then we can not assume they will be controlled and have therefore held most of them constant at 2002 levels. For such Class I areas with high contributions from international sources, the comparison with the 2018 URP point is not very meaningful since the 2018 URP assumes such sources will be reduced. A more meaningful comparison would be to focus on the U.S. man-made contributions to visibility impairment at the Class I areas and develop a URP glidepath and 2018 URP point that is aimed at eliminating the U.S. anthropogenic emissions contributions to visibility impairment at Class I areas for the worst 20 percent days in 2064.

The CAMx 2002 base case PSAT PM source apportionment results were processed to identify the portion of the 2000-2004 Baseline extinction that was due to U.S. anthropogenic emissions (i.e., man-made sources). The contributions of source groups that included on-road mobile, non-road mobile, elevated point sources, low-level point sources and area sources from the PSAT source regions covering the U.S. states and Gulf of Mexico (Figure 5-8) were assumed to make up the U.S. anthropogenic contributions (i.e., excluding the Natural source category, all sources from the Mexico and Canada source regions and boundary conditions). Note that off-shore marine emissions in the Pacific and Atlantic Oceans and Gulf of Mexico were included in the U.S. anthropogenic emissions definition because they were in source regions associated with states or the Gulf of Mexico. As off-shore marine emissions may not be controllable by U.S. agencies and they were assumed to remain unchanged going from 2002 to 2018, then the 2018 visibility projections for the U.S. anthropogenic component are overstated.

The 2064 objective for the U.S. anthropogenic emissions glidepath would be no contributions on the worst 20 percent days. This does not mean the 2064 U.S. anthropogenic extinction objective

is zero, rather the U.S. anthropogenic plus natural background is less than the Natural Conditions for the worst 20 percent days. The PSAT results were used to define the natural background contributions on the current worst 20 percent days which was subtracted from the EPA default Natural Conditions to obtain the 2064 objective for the U.S. anthropogenic emissions contributions. Here the PSAT derived natural background was defined as the sum of the contributions from the Natural source category, secondary organic aerosol from biogenic sources (SOAB) and half of the boundary conditions. For example, Figure 5-17 top left displays the US anthropogenic emissions glidepath for CACR. The PSAT natural sources contribution (=Natural Source Category + SOAB + $\frac{1}{2}$ BC) is approximately 13 Mm^{-1} so that is subtracted from the 2064 Natural Background ($\sim 32 \text{ Mm}^{-1}$, see figure 5-16) to obtain a 2064 end point of $\sim 19 \text{ Mm}^{-1}$ for the glidepath. The 2002 PSAT results applied to the 2000-2004 Baseline extinction estimates that 111 Mm^{-1} of the extinction is due to U.S. anthropogenic emissions which form the starting point for the glidepath. The curvature in the US anthropogenic glidepath is introduced the same way as for the extinction based glidepath to account for the logarithmic relationship between extinction and deciview.

Figure 5-17 displays the U.S. anthropogenic emissions extinction glidepaths and comparison with the 2018 visibility projections for extinction due to U.S. anthropogenic emissions on the worst 20 percent days. As seen by the standard linear deciview glidepaths discussed in Chapter 4, the U.S. anthropogenic emissions 2018 URP point is achieved by a wide margin at the four Class I areas in Arkansas and Missouri (CACR, UPBU, HRGL and MING). BRET that achieved 94% of the 2018 URP point obtains similar results using the U.S. anthropogenic emissions glidepath achieving 96% of the 2018 URP point. As discussed above, the inclusion of the off-shore marine emissions in the U.S. anthropogenic emissions will greatly affect the BRET Class I area so that actual reduction in U.S. anthropogenic emissions extinction would be greater and may even achieve the 2018 URP point if off-shore marine vessels were classified as not being part of the U.S..

The BOWA and VOYA northern Minnesota Class I areas achieved, respectively, 69% and 53% of the 2018 URP point using the standard EPA default deciview glidepaths and projection techniques (Figure 4-4). Using the U.S. anthropogenic glidepaths BOWA and VOYA achieve 92% and 86% of the 2018 point, respectively (Figure 5-17). WIMO that came up approximately 40% short of achieving the 2018 URP point using the deciview glidepath comes up under 20% short using the U.S. anthropogenic emissions glidepath.

The two Texas Class I areas also come up short in achieving the 2018 URP point using the U.S. anthropogenic emissions glidepaths, but not as short as when the linear deciview glidepaths are used. BIBE increases from 26% to 67% and GUMO increases from 34% to 49%. One reason these two Class I areas fail to achieve the 2018 point for U.S. anthropogenic emissions is because of the high contributions of Soil and CM and little change in precursor emissions of these species between 2002 and 2018.

Figure 5-17. Glidepaths and 2018 visibility projections based on visibility due to U.S. anthropogenic emissions at CENRAP Class I areas.

5.8 Use of Original IMPROVE Equation

2018 visibility projections were also made using the CENRAP Typ02g and Base18g CMAQ modeling results and the original (old) IMPROVE equation. Figure 5-18 displays a DotPlot that compares the 2018 Base G visibility projections using the new IMPROVE algorithm (NIA) and the original IMPROVE algorithm (OIA). In general the new IMPROVE equation results in more optimistic 2018 visibility projections than the original IMPROVE equation. For the Texas and WRAP Class I areas, the 2018 visibility projections are nearly identical using the two IMPROVE equations. For the four Class I areas in Arkansas and Missouri the 2018 visibility projections using the new IMPROVE equation are from 7 to 21 percentage points more optimistic than the original IMPROVE equation. In the case of UPBU, HEGL and MING the 2018 visibility projections go from not achieving to achieving the 29018 URP point when switching from the old to new IMPROVE equation.

5.9 Visibility Trends

Figure 5-19 displays trends in visibility impairment at the CENRAP Class I areas using the period of record of measurements at the associated IMPROVE monitor and the new IMPROVE equation. These trends include trends for the worst 20 percent days, the best 20 percent days and all IMPROVE sampled days during a year. The EPA guidance procedures were used to construct the worst and best 20 percent days that includes a minimum data capture requirement (EPA, 2003a), whereas no such minimum data capture was applied when looking at the “annual average” of all IMPROVE sampled days trends. So care must be taken when analyzing trends for the all sampled IMPROVE days trends as there could be large missing periods with high or low extinction that are not being account for. The WRAP Technical Support System (TSS) website was used to calculate the visibility trends at the CENRAP Class I areas that includes IMPROVE data from start of recording through 2004 and includes no data filling (see: <http://vista.cira.colostate.edu/TSS/Default.aspx>).

Trends in visibility at CACR has three years of data (2002-2004) for the worst and best 20 percent days and five years for the IMPROVE sampled days trends. Although it is hard to come to any conclusions regarding trends with just three years of data, there does seem to be a general downward trend, that is also supported by the five year trend in the IMPROVE sampled days.

A much longer trend plot is available for UPBU that includes 12 years of data for the worst and best 20 percent days (Figure 5-19b). Although there is a lot of a year-to-year variation in the visibility trends with cleaner years occurring in 1997, 2001 and 2004, there does appear to be a slight trend toward improved visibility at UPBU.

There is insufficient data to calculate the worst or best 20 percent days visibility for any year at the BRET Class I area so only the IMPROVE sampled days trends are presented (Figure 5-19c). The trends at BRET are inconclusive and given the large amounts of missing data at this site it is difficult to interpret the results.

There is also a lot of missing years in the worst and best 20 percent days for the BOWA Class I area making it difficult to interpret (Figure 5-19d). But visibility appears to be more impaired in the early 1990s than in more current years so improvements have been seen. VOYA has five years of valid data and shows worsening visibility for 2000-2003, and then improved visibility in 2004. It is unclear whether the 2004 improved visibility is a trend or just due to variations in meteorology so no conclusions can be drawn.

Although a downward trend in visibility impairment appears to be occurring at the two Missouri Class I areas (Figure 5-19f-g), given that there are only three years available for HEGL and lots of missing data for MING these trends are inconclusive.

Three years (2002-2004) of visibility trends for the worst and best 20 percent days are available for WIMO (Figure 5-19h). The most impaired year from the three years for the worst 20 percent days is the most recent (2004). Again, the time period is too short to draw any conclusions on trends in visibility at WIMO.

The two Texas Class I areas have a relatively long period of record. There is a lot of year-to-year variability in the visibility measurements that make interpreting the trends difficult. 1998 appears to be an anomalously high visibility impairment year at BIBE and due to the much higher OMC extinction indicates that the year was likely impacted by smoke from fires. GUMO has lots of year to year variability in CM and Soil which are likely due to occurrences of impacts due to wind blown dust. Even taking Soil and CM out of the interpretation it is difficult to interpret any trend in visibility at the two Texas Class I areas. The higher visibility impairment in 1998 and 1999 suggests a downward trend but that may be just due to more adverse meteorological and natural emissions (e.g., wildfires) in these two years than any real long term trend.

Figure 5-19a. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Caney Creek (CACR), Arkansas for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19b. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Upper Buffalo (UPBU), Arkansas for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Insufficient Data to Calculate Best 20 Percent days at BRET

Figure 5-19c. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Breton Island (BRET), Louisiana for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19d. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Boundary Waters (BOWA), Minnesota for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19e. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Voyageurs (VOYA), Minnesota for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19f. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Hercules Glade (HEGL), Missouri for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19g. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Mingo (MING), Missouri for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19h. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Wichita Mountains (WIMO), Oklahoma for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19i. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Big Bend (BIBE), Texas for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

Figure 5-19j. Time series of observed IMPROVE reconstructed light extinction (New IMPROVE) at Guadalupe Mountains (GUMO), Texas for the average of the Worst 20 Percent days (top), Best 20 Percent days (middle) days and all IMPROVE sampling days during the period of record.

APPENDIX A

**Model Performance Evaluation of the 2002 36 km
MM5 Meteorological Model Simulation used in the
CENRAP Modeling and Comparison to VISTAS Final
2002 36 km MM5 and WRAP Interim
2002 36 km MM5 Simulations**

The CENRAP 2002 36 km MM5 simulation (Johnson, 2007) was evaluated against observed surface and upper-air meteorological observations and observed precipitation amounts and its performance was compared against the VISTAS final and the WRAP interim 2002 36 km MM5 simulations. The CENRAP, VISTAS and WRAP 2002 36 km MM5 simulations used several common science options:

- Lambert Conformal Projection with center at (97°, 40°) and standard parallels at (33°, 45°).
- 164 by 128 36 km by 36 km horizontal grids covering the continental U.S. and adjacent regions.
- 34 vertical layers up to 100 mb (~15 km AGL).
- Pleim-Xiu Land Surface Module (LSM).
- Asymmetric Convective Mixing (ACM) Planetary Boundary Layer (PBL) model.
- RRTM long-wave radiation.
- Dudhia short-wave radiation.
- No Shallow convection.

However, there were some differences in the choice of science options:

- VISTAS and CENRAP MM5 simulations used the Kain Fritsch 2 cumulus parameterization, whereas WRAP MM5 used Kain Fritsch 1.
- VISTAS and CENRAP MM5 simulations used the Reisner 1 moist physics while WRAP MM5 used Reisner 2.
- All three MM5 simulations used Four Dimensional Data Assimilation (FDDA) analysis nudging at the surface for winds, but WRAP also used surface analysis nudging to temperature and moisture.
- All three MM5 simulations used analysis nudging FDDA above the PNL to winds, temperature and moisture.

Much of the difference in the model performance for the three MM5 simulations was related to the surface temperature and moisture analysis nudging used in the interim WRAP MM5 simulations that resulted in better surface temperature model performance, but caused instabilities resulting in degradation in meteorological model performance above the surface. The final WRAP 2002 36 km MM5 simulation did not use the surface temperature and moisture FDDA and used the Betts-Miller cumulus scheme instead of Kain Fritsch that resulted in much improved meteorological model performance in the western States (Kemball-Cook et al., 2005).

A.1 Surface Meteorological Model Performance

The performance of the three MM5 simulations at the surface was evaluated through comparisons against observed surface wind, temperature and humidity measurements from the ds472 observational database. The METSTAT program was used to evaluate the MM5 simulations for each month of 2002 and across the 11 subdomains shown in Figure A-1. These subdomains are as follows:

- 1 = Pacific NW
- 2 = SW
- 3 = North
- 4 = Desert SW
- 5 = CenrapN
- 6 = CenrapS
- 7 = Great Lakes
- 8 = Ohio Valley
- 9 = SE
- 10 = NE
- 11 = MidAtlantic

Emery and Tai (2001) have developed model performance benchmarks by analyzing over 30 MM5RAMS meteorological model simulations and tabulating the typical level of performance that a good meteorological model achieves. These performance benchmarks are not intended to be pass/fail grades; rather they provide a framework to evaluate the model performance against past applications. Since many of the past MM5/RAMS meteorological model simulations that the benchmarks were developed from were in support of urban ozone modeling that are typically fairly stagnant conditions with little or no precipitation and involved multiple iterations to achieve the final base case simulation. Thus, we may not expect the 2002 annual MM5 simulations to achieve a similar level of performance given the complicating factors of precipitation and complex terrain associate with many Class I areas in the west. Table A-1 lists the meteorological model performance benchmarks for wind speed, wind direction, temperature and humidity.

Table A-1. Meteorological model performance benchmarks (Source: Emery et al., 1999).

Statistic	Wind Speed	Wind Direction	Temperature	Humidity
RMSE	≤ 2 m/s			
Mean Bias	$\leq \pm 0.5$ m/s	$\leq \pm 10^\circ$	$\leq \pm 0.5$ K	$\leq \pm 1.0$ g/kg
Index of Agreement	≤ 0.6		≤ 0.8	≤ 0.6
Gross Error		$\leq 30^\circ$	≤ 2.0 K	≤ 2.0 g/kg

Below we present the evaluation of the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations against surface meteorological observations for the four seasonal months of January, March, July and October and the CENRAP North (CenrapN) and CENRAP South (CenrapS) subdomains (i.e., subdomains 5 and 6 in Figure A-1). The surface evaluation of the three MM5 2002 36 km simulations outside of the CENRAP subdomains can be found in Kemball-Cook et al., (2004).

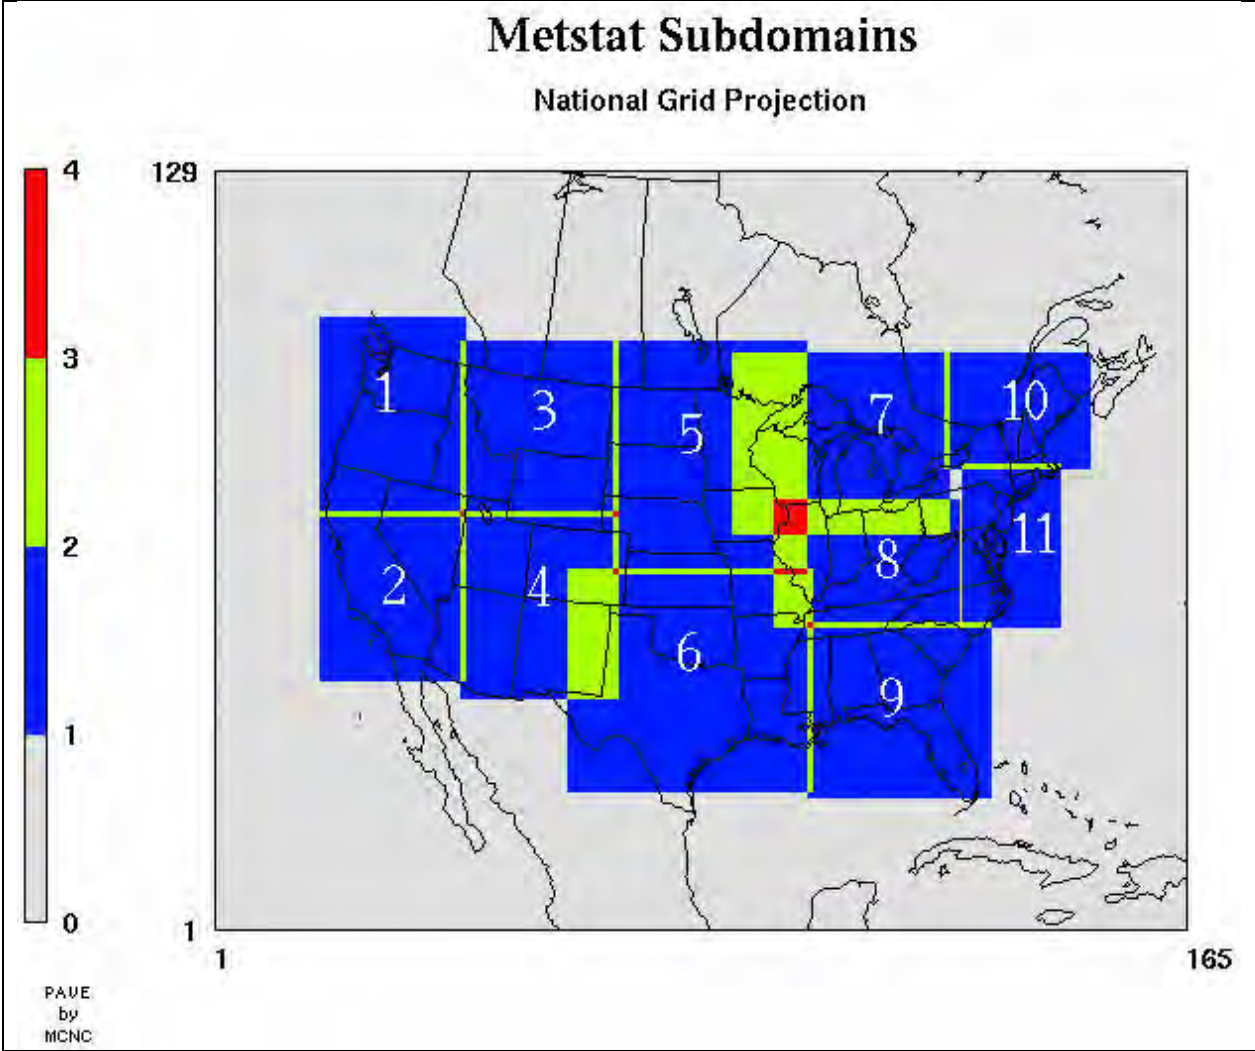

Figure A-1. Eleven subdomains where monthly evaluation of the MM5 simulations surface model performance was evaluated.

A.1.1 Temperature

Figure A-2 displays the surface temperature model performance for the CENRAP, VISTAS and WRAP 2002 36 km MM5 simulations in the CenrapN and CenrapS subdomains and the months of January, March, July and October. The WRAP MM5 simulations are performing best for January temperature in both CENRAP domains exhibiting low bias and the lowest error that are within the benchmark. The VISTAS MM5 run is performing next best with bias well within the benchmark and error within but close to the error benchmark. The CENRAP MM5 simulation performs well for the CenrapS domain with zero bias and error within, but approaching the benchmark. However, the CENRAP performance for the CenrapN domain does not achieve the performance benchmarks due to a too cold bias.

The temperature performance in March is similar to January with both the VISTAS and WRAP MM5 simulations achieving the benchmark for both CENRAP subdomains. Again the CENRAP MM5 simulation has a near zero bias and achieves the error benchmark in the CenrapS subdomain, but is too cold in the CenrapN domain falling out of the bias benchmark range.

In July the three simulations achieve the temperature benchmark in both CENRAP subdomains, although the WRAP MM5 simulation is cooler with the CenrapS bias right at the -0.5 K lower bound benchmark. The CENRAP MM5 simulation is slightly warmer than the VISTAS MM5 simulation.

In October, all three MM5 simulations achieve the temperature performance benchmarks. The WRAP MM5 simulation performs best with near zero bias and lower error than either the VISTAS or CENRAP simulations. The VISTAS and CENRAP MM5 simulations exhibit nearly identical temperature performance in October with a near zero bias for the CenrapS subdomain and a cool bias for the CenrapN subdomain.

In conclusion, the WRAP MM5 simulation is always performing best for surface temperature with the lowest bias and usually the lowest error. The VISTAS MM5 simulation is performing next best as the CENRAP MM5 simulation exhibits a cool bias for the CenrapN subdomain in January and March that exceed the performance benchmarks.

CENRAP / VISTAS / WRAP January Temperature Performance Comparison Over CENRAP Domain

CENRAP / VISTAS / WRAP March Temperature Performance Comparison Over CENRAP Domain

Figure A-2a. Temperature performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and January (top) and March (bottom).

CENRAP / VISTAS / WRAP July Temperature Performance Comparison Over CENRAP Domain

CENRAP / VISTAS / WRAP October Temperature Performance Comparison Over CENRAP Domain

Figure A-2b. Temperature performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

A.1.2 Humidity

The humidity performance for the three MM5 simulations is comparable and always achieves the performance benchmarks. The humidity bias is always near zero for all three runs and four months. In January, March and October the humidity error is at or less than half of the 2.0 g/kg benchmark. However, in July there is more error in the humidity with it within but approaching the benchmark value for all three models.

In conclusion, all three MM5 simulations achieved the humidity benchmark performance goals for all months studied. No model simulation exhibited superior performance over another.

CENRAP / VISTAS / WRAP January Humidity Performance Comparison Over CENRAP Domain

CENRAP / VISTAS / WRAP March Humidity Performance Comparison Over CENRAP Domain

**CENRAP / VISTAS / WRAP July Humidity Performance
Comparison Over CENRAP Domain**

**CENRAP / VISTAS / WRAP October Humidity Performance
Comparison Over CENRAP Domain**

Figure A-3b. Humidity performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

A.1.3 Winds

The model performance for wind speed and direction and January is almost identical and within the benchmarks for all three models and both CENRAP subdomains. In fact, the performance is so close the CenrapS symbols are plotted over and obliterate the CenrapN performance symbols.

In March, the wind performance is within the benchmark for all three MM5 simulations, which exhibit similar performance statistics. The wind performance in the CenrapS subdomain is slightly better than CenrapN with the CENRAP MM5 simulations showing the largest wind speed RMSE in the CenrapN subdomain, although still within the benchmarks.

Slight degraded wind direction performance is seen in July with the error increases to just below 20 degrees to just below the 30 degree benchmark value for all three models. Similar wind speed RMSE is seen for all three models.

The October wind performance is within the benchmarks for all three models with performance between that seen for January/March and July.

In summary, the models exhibited similar model performance for surface wind speed and direction.

CENRAP / VISTAS / WRAP January Wind Performance Comparison over CENRAP Domain

CENRAP / VISTAS / WRAP March Wind Performance Comparison Over CENRAP Domain

Figure A-4a. Wind Speed and Wind Direction performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and January (top) and March (bottom).

Figure A-4b. Wind Speed and Wind Direction performance for the CENRAP, VISTAS and interim WRAP 2002 36 km MM5 simulations, the CenrapN and CenrapS subdomains and July (top) and October (bottom).

A.2 Upper-Air Meteorological Evaluation

Figure A-5 displays an example comparison of the vertical profile of predicted and observed winds and temperature for Midland, Texas and January 7 2002 at 12 GMT (6am LST) and for July 16, 2002 at 00 GMT (6pm LST). Above the surface, all three models do a good job in replicating the observed temperature, dew point temperature and winds at 6a on January 7, 2002. Although the WRAP MM5 simulation predicts the surface temperature better than the other two simulations, the vertical structure of the temperature and the surface temperature inversion is not reproduced as well.

All three models understate the afternoon PBL depth on July 16, 2002 at Midland Texas. This phenomenon was seen at other sites as well.

The upper-air meteorological model evaluation found that all three models had difficulty reproducing the observed nocturnal inversion. The day time convective mixing depths were also typically underestimated.

Although the WRAP MM5 simulation reproduced the surface temperature the best of the three models, it was worst at reproducing the observed vertical temperature structure and resultant level of mixing. These results are likely due to the surface data assimilation of temperature employed by the WRAP interim MM5 simulation and resulted in WRAP eliminating the surface temperature and humidity FDDA in their final simulation.

Figure A-5. Comparison of predicted and observed vertical temperature, dew point and winds profiles for the CENRAP (left), VISTAS (middle) and WRAP (right) at Midland Texas on January 7, 2002 at 12 GMT (top) and July 16, 2002 at 00 GMT (bottom).

A.4 Precipitation Model Performance Evaluation

The three MM5 model simulation precipitation estimates were evaluated by comparing the monthly average spatial distributions and amounts with observed values from the observed CPC 0.25 by 0.25 degree (approximately 28 km by 28 km) gridded analysis fields. The CPC analysis fields are gridded from on U.S. land-based observations, consequently the gridded observed fields are not available over the oceans and Canada and Mexico. The CPC observed monthly average precipitation fields were displayed using the MM5 modeling domain. The MM5 total precipitation estimates were accumulated for a month and plotted. Here total precipitation includes both explicit large scale synoptic precipitation as well as the subgrid-scale convective precipitation from the cumulus parameterization (Kain Fritsch 1 or 2).

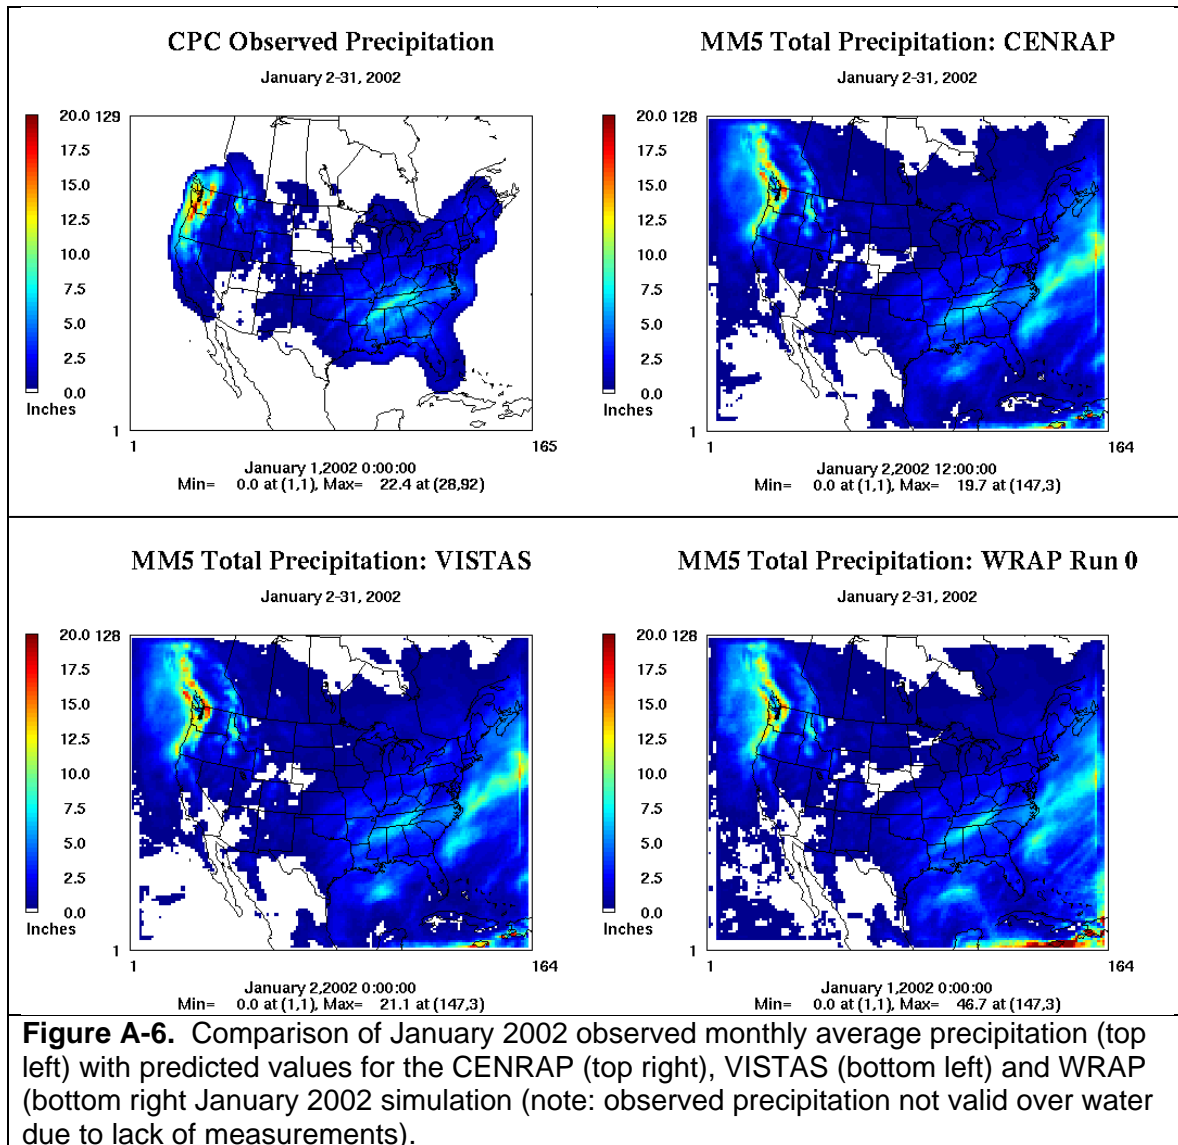

Figures A-6 through A-9 display the monthly average precipitation fields for the months of January, March, July and October and the CPC observed and CENRAP, VISTAS and interim WRAP MM5 simulations. In January (Figure A-6), all three models reproduce the observed monthly average precipitation well with enhanced predicted and observed precipitation over the Pacific Northwest and the Appalachian Mountains. The MM5 simulations also estimated enhanced precipitation in off-shore areas north of Seattle, over the Atlantic Ocean and in the Gulf of Mexico that can not be either confirmed or refuted by the CPC observations. MM5 does overstate the amount of precipitation in January over the northern CENRAP region including over Minnesota, Iowa and Nebraska.

The three models also do a good job in reproducing the observed spatial distribution and amounts of the precipitation in March 2002 (Figure A-7). Elevated precipitation areas in the Pacific Northwest and across the lower Midwest from Arkansas and up into the Ohio River Valley and adjacent areas. The MM5 simulations do understate the highest observed precipitation amounts in Arkansas. The MM5 simulations also overstate the amount of precipitation in the desert southwest (Four Corners) area in March.

The MM5 monthly average precipitation performance is dramatically worse in July 2002 (Figure A-8). Precipitation is overstated by all three MM5 simulations throughout the U.S. and particularly in the southern states, from Arkansas across Texas to the southeastern U.S. particularly Florida South and North Carolina. This over-prediction bias is due to convective precipitation from the cumulus parameterization (either Kain Fritsch 1 or 2). This overactive precipitation is the result of the over-prediction bias I humidity seen in many subdomains (see Table A-3b and Kemball-Cook et al., 2004a).

In October 2002, the three MM5 simulations reproduced the observed monthly average rainfall fairly well across the U.S. (Figure A-9). The models predict the location of the maximum precipitation in southern Louisiana well, but under-predict the magnitude, which may be due to a slight spatial displacement offshore in the Gulf of Mexico. The MM5 simulations understate the precipitation over the CENRAP region, which explains the dry humidity bias in the CenrapS subdomain in October (Figure A-3b).

In conclusion, the three MM5 simulations do a good job in simulating the observed precipitation when it is due to synoptic weather systems. However, when precipitation is due to convective activity as seen in July that is simulated by the MM5 cumulus parameterization, MM5 greatly overstates the precipitation amounts. This is particularly pronounced in the southern states from the Four Corners area to Florida with the interim WRAP simulation exhibiting the largest over-prediction bias. In the final WRAP MM5 simulation the Betts-Miller cumulus parameterization was used that greatly reduced the convective precipitation amounts resulting in better model performance (Kemball-Cook et al., 2005). However, an overestimation bias under convective precipitation conditions still was present.

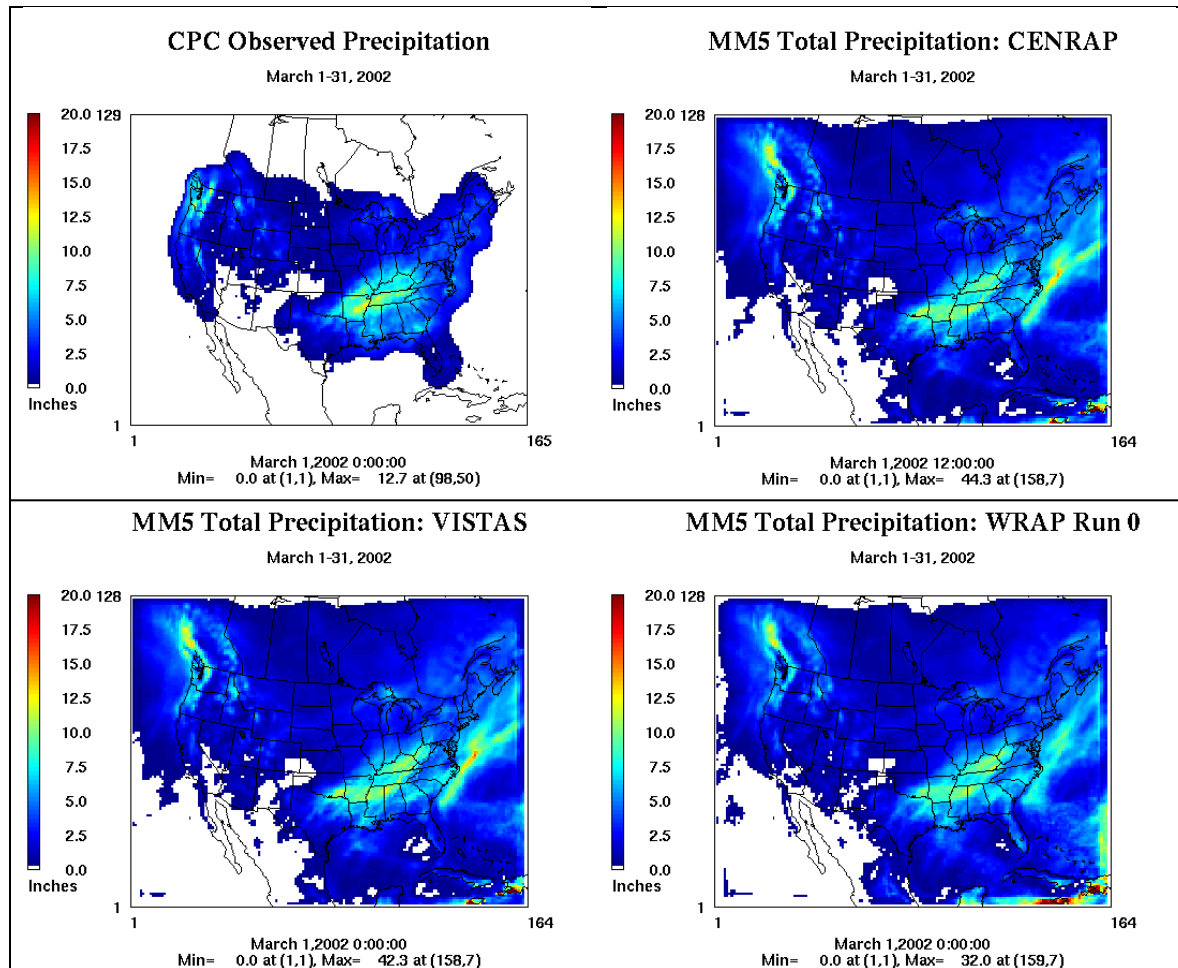

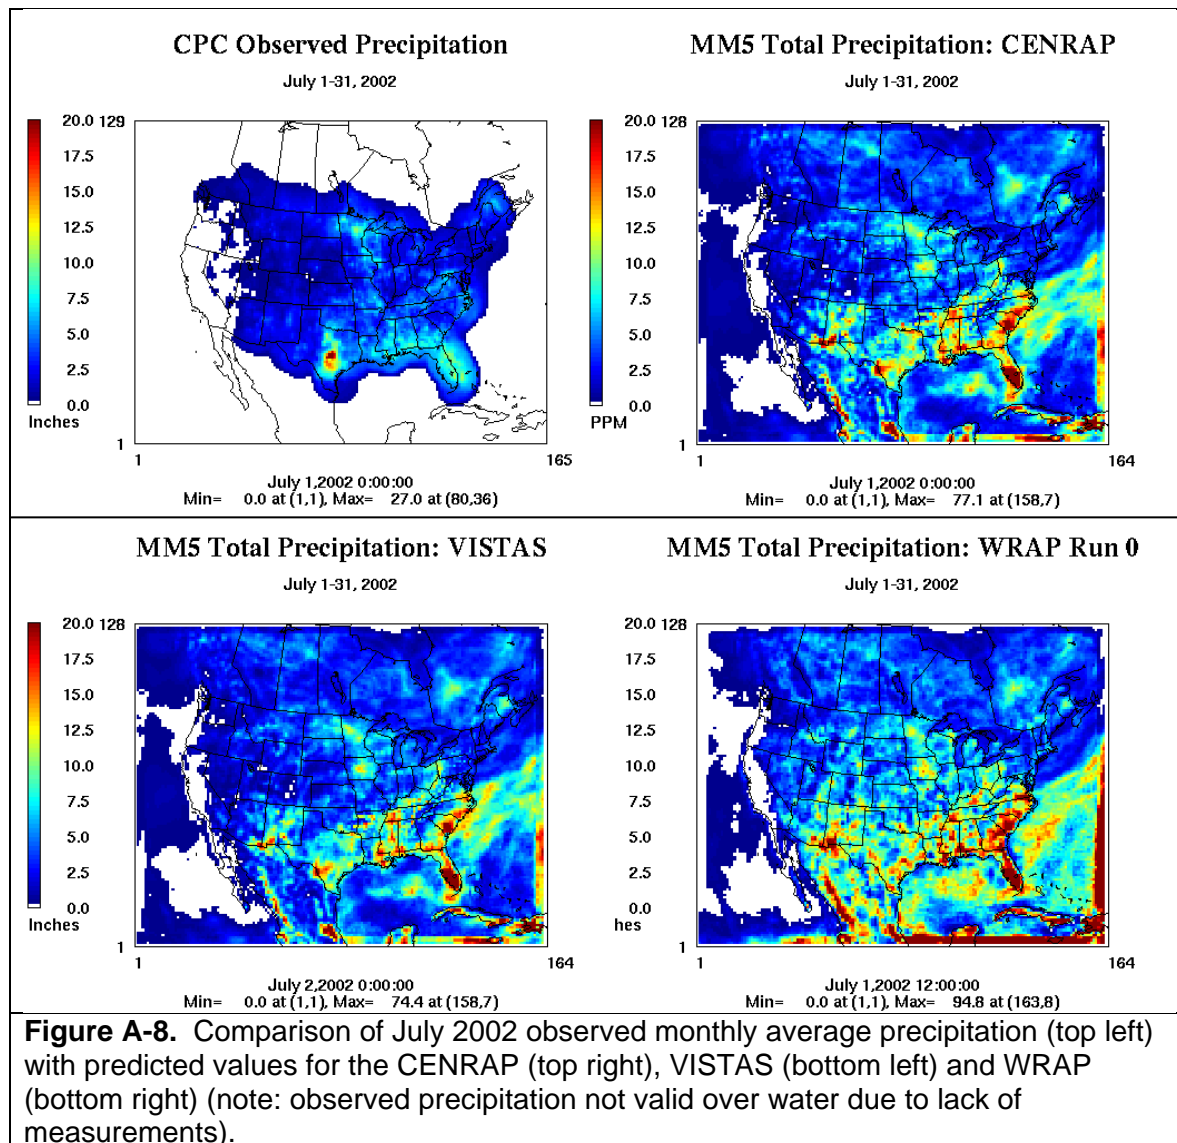

Figure A-7. Comparison of March 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right January 2002 simulation (note: observed precipitation not valid over water due to lack of measurements)).

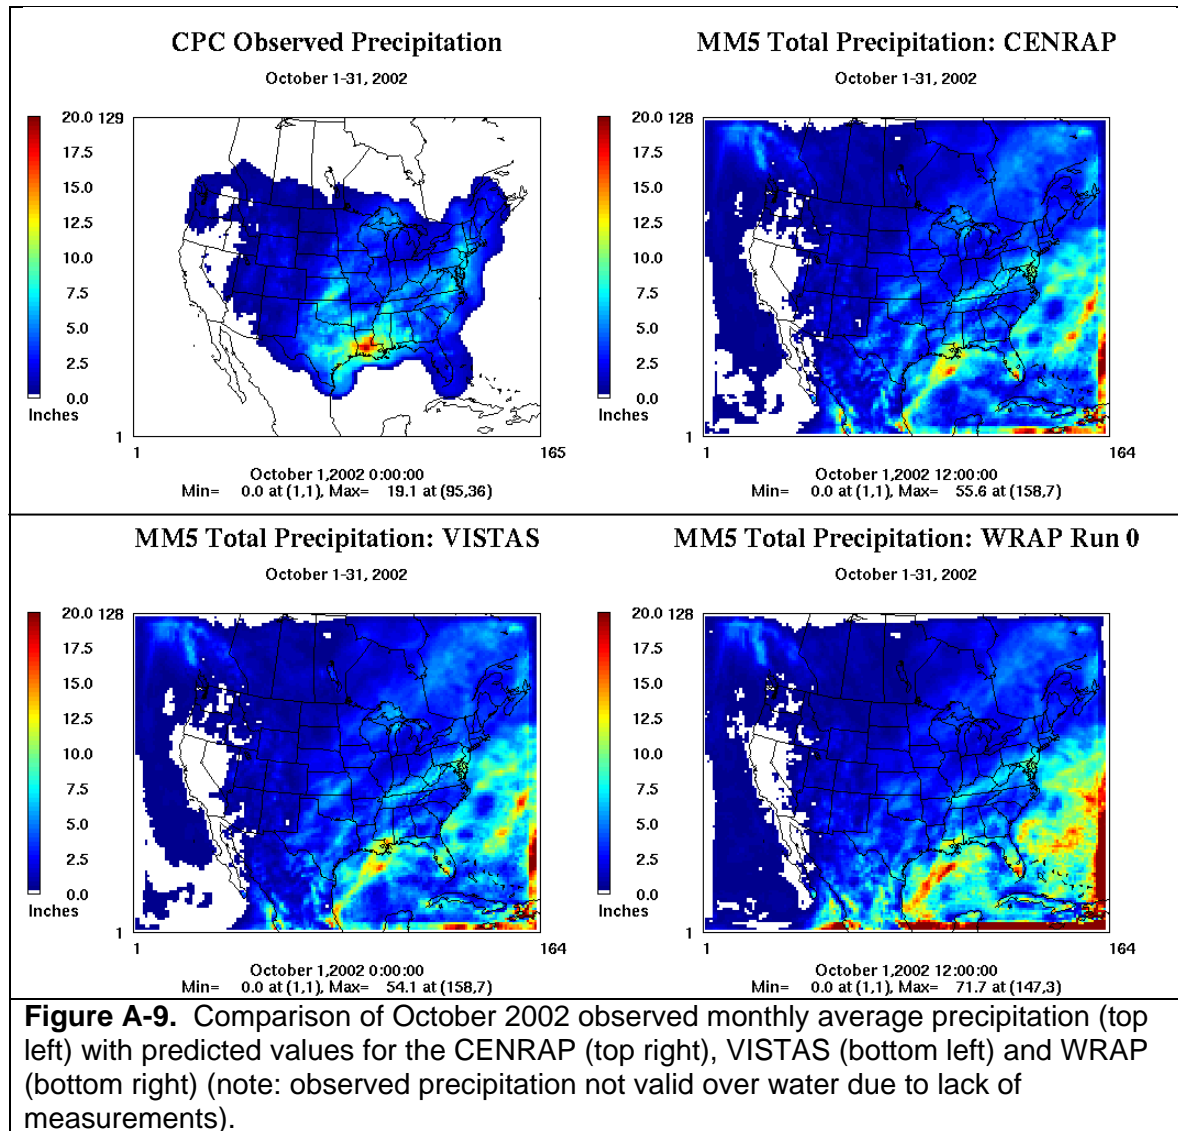

Figure A-9. Comparison of October 2002 observed monthly average precipitation (top left) with predicted values for the CENRAP (top right), VISTAS (bottom left) and WRAP (bottom right) (note: observed precipitation not valid over water due to lack of measurements).

APPENDIX C

Model Performance Evaluation for the CMAQ 2002 Base F Base Case Simulation in the CENRAP Region

C.1 2002 Typical Base F Model Performance Evaluation Scenario

This Appendix presents the operational evaluation of the CMAQ model for the 2002 36 km Typical Base F emissions scenario. The final CENRAP 2002 and 2018 emissions scenarios used in the 2018 visibility projections was Base G. The main differences between Base G and Base F emissions inventories were updated Mexican emissions in the northern states, addition of Mexican emissions in the southern states that were not included in CENRAP's emission inventories prior to Base G and correction of a few point source stack parameters and emissions in the CENRAP states and Canada (see: http://pah.cert.ucr.edu/aqm/cenrap/OA_typ02g36.plots/log_inv_catg_Typ02g.doc). Figure C-1 displays the differences in annual average PM_{2.5} and ozone concentrations between the 2002 Typical Base G and Base F simulations. Most of the differences in the two simulations are concentrations within Mexico where no monitoring data were available for the model evaluation. Thus, given the very small differences between the 2002 Typical Base F and G base case simulations, the model performance evaluation is presented for just the 2002 Typical Base F simulation (for additional comparisons of Base G and F see: http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#typ02gvstyp02f_mpe).

The CENRAP emissions and air quality modeling initially conducted 2002 base case modeling for two 2002 base case emissions scenarios: a 2002 Actual emissions base case; and a 2002 Typical emissions base case. For the 2002 Actual base case, day-specific SO₂ and NO_x emissions for large stationary point sources were used based on measured continuous emissions monitoring (CEM) data along with actual 2002 fire emissions. In the 2002 Typical base case, emissions for large stationary sources and fires were more representative of the 2000-2004 Baseline period. For large stationary sources' typical emissions, 5-years of CEM data were analyzed and typical seasonal and diurnally varying emissions were defined for when the sources were operating. For the typical fire emissions, the locations of the 2002 Actual fire emissions were retained, but the intensity was reduced or increased to match the average conditions over the 5-year Baseline. The original intent of the CENRAP modeling of both a 2002 Actual and Typical base cases was to use the 2002 Actual base case for the model performance evaluation and the 2002 Typical base case with the 2018 emission scenario for the 2018 visibility projections.

The need to generate both the 2002 Typical and Actual base case inventories and perform CMAQ model simulations each time an emissions update or correction to the modeling occurred became burdensome and potentially could compromise the CENRAP schedule and available resources. For the Base F vintage emissions database, a model performance evaluation was conducted that compared the model performance of the 2002 Actual and Typical Base F CMAQ base case simulations to determine whether use of the Actual emissions substantially changed the interpretation of the model performance. The maximum change in model performance between the 2002 Actual and Typical base case was for sulfate and occurred during the summer months, when sulfate is the highest. Figure C-2 displays sulfate (SO₄), nitrate (NO₃), elemental carbon (EC) and organic matter carbon (OMC) performance for July 2002 across IMPROVE sites in the CENRAP region for the 2002 36 km Actual and Typical Base F CMAQ base case simulations. Although differences in predicted 24-hour SO₄ concentrations are sometimes discernable in the scatter plot, the basic model performance conclusions remains the same and the difference in fractional bias (-48% vs. -49%) and fraction error (58% vs. 59%) are not significant. Similarly, the difference in NO₃ model performance between the Actual and Typical Base F simulations are not significant. The performance of the CMAQ Actual and Typical simulation for EC and OMC is essentially identical. Given the similarity of the 2002 Base F Actual and Typical model performance evaluation, future CENRAP CMAQ model performance analysis were just performed on the Typical simulation.

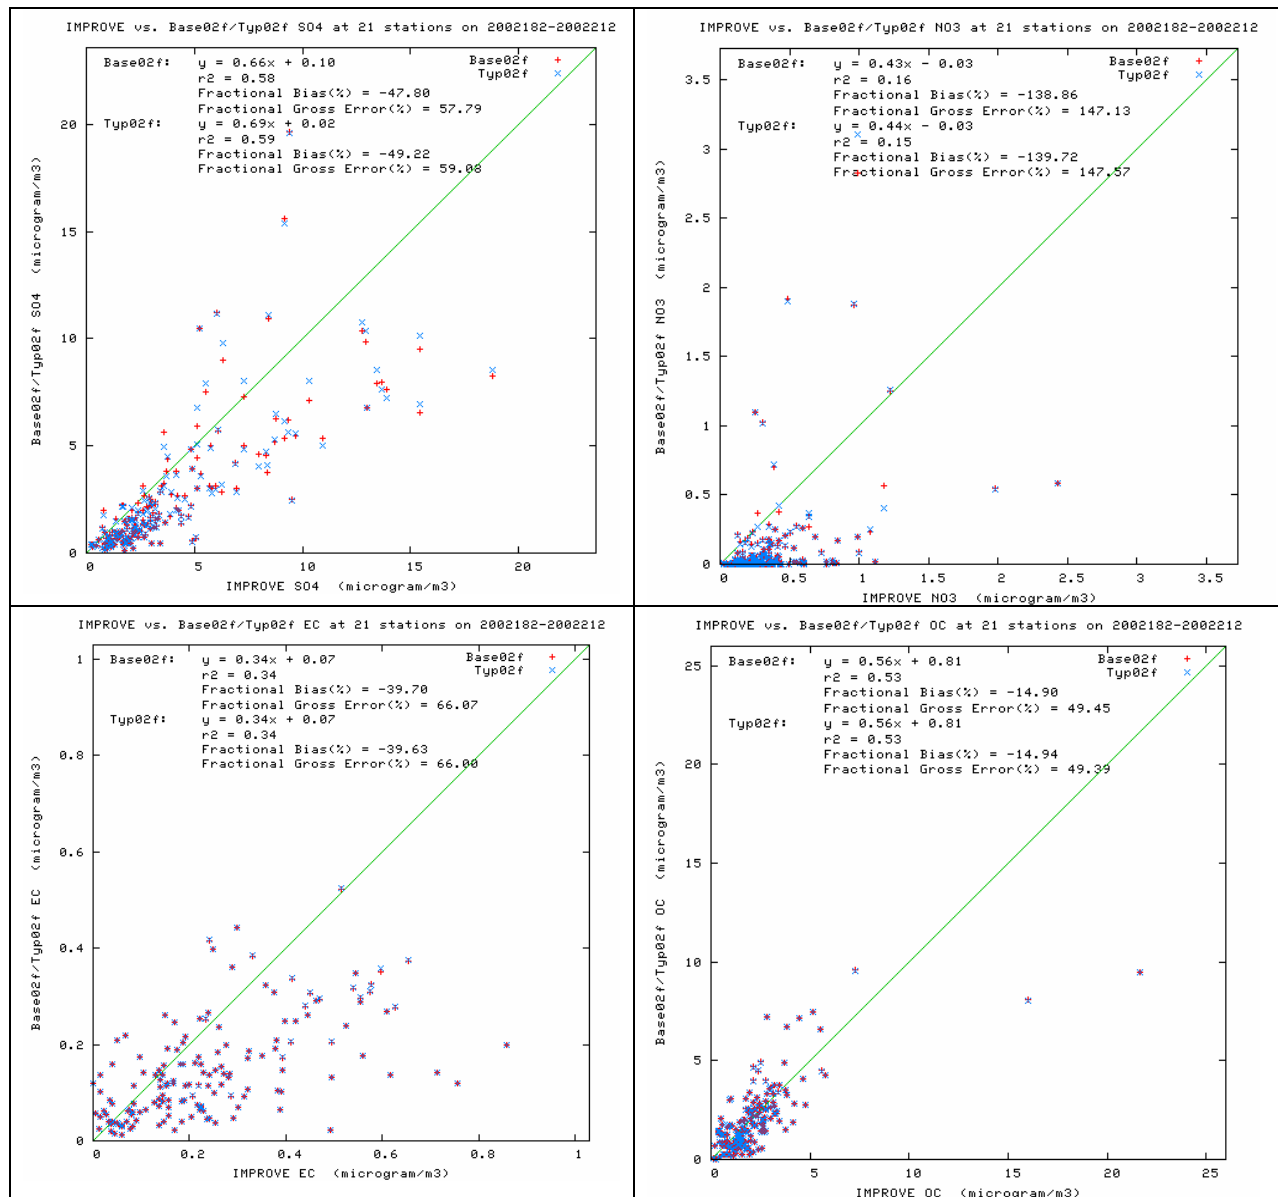

Figure C-2. Comparison of SO4 (top left), NO3 (top right), EC (bottom left) and OMC (bottom right) model performance for July 2002, the CENRAP region and the 2002 36 km Base F Actual (red) and Typical (blue) CMAQ base case simulation.

C.2 CMAQ Evaluation Methodology

EPA's integrated ozone, PM_{2.5} and regional haze modeling guidance calls for a comprehensive, multi-layered approach to model performance testing, consisting of the four major components: operational, diagnostic, mechanistic (or scientific) and probabilistic (EPA, 2007). The CMAQ model performance evaluation effort focused on the first two components, namely:

- **Operational Evaluation:** Tests the ability of the model to estimate PM concentrations (both fine and coarse) and the components at PM₁₀ and PM_{2.5} including the quantities used to characterize visibility (i.e., sulfate, nitrate, ammonium, organic carbon, elemental carbon, other PM_{2.5}, and coarse matter (PM_{2.5-10}). This evaluation examines whether the measurements are properly represented by the model predictions but does not necessarily ensure that the model is getting “the right answer for the right reason”; and
- **Diagnostic Evaluation:** Tests the ability of the model to predict visibility and extinction, PM chemical composition including PM precursors (e.g., SO_x, NO_x, and NH₃) and associated oxidants (e.g., ozone and nitric acid); PM size distribution; temporal variation; spatial variation; mass fluxes; and components of light extinction (i.e., scattering and absorption).

The diagnostic evaluation also includes the performance of diagnostic tests to better understand model performance and identify potential flaws in the modeling system that can be corrected. The diagnostic evaluation may also include the use of “probing tools” to understand why the model obtains a given prediction; probing tools include Process Analysis (PA), decoupled direct method (DDM) and source apportionment (SA).

In this final model performance evaluation for the 2002 Typical Base F CMAQ simulation, the operational evaluation has been given the greatest attention since this is the primary thrust of EPA's modeling guidance. However, we have also examined certain diagnostic features dealing with the model's ability to simulate sub-regional and monthly/diurnal gas phase and aerosol concentration distributions. In the course of the CENRAP and other modeling process numerous diagnostic sensitivity tests were performed to investigate and improve model performance. Key diagnostic tests performed are discussed and the results for the rest are available on the CENRAP modeling website: <http://pah.cert.ucr.edu/aqm/cenrap/index.shtml>.

C.2.1 Ambient Air Quality Data for CENRAP Model Evaluation

The ground-level model evaluation database for 2002 was compiled by the modeling team using several routine and research-grade databases. The first is the routine gas-phase concentration measurements for ozone, NO, NO₂ and CO archived in EPA's Aerometric Information Retrieval System (AIRS) Air Quality System (AQS) database. Other sources of observed information come from the various PM monitoring networks in the U.S. These include the: (a) Interagency Monitoring of Protected Visual Environments (IMPROVE); (b) Clean Air Status and Trends Network (CASTNET); (c) Southeastern Aerosol Research and Characterization (SEARCH); (d) EPA Federal Reference Method PM_{2.5} and PM₁₀ Mass Networks (EPA-FRM); (e) EPA Speciation Trends Network (STN) of PM_{2.5} species; and (f) National Acid Deposition Network (NADP). These PM

monitoring networks may also provide ozone and other gas phase precursors and product species, and visibility measurements at some sites. During the course of the CENRAP modeling, the numerous base case simulations were evaluated across the continental U.S. In this section we focus our evaluation on model performance within the CENRAP region. Table C-1 summarizes the observations collected at each monitoring network within the CENRAP region and their sampling frequency with Figure C-3 displaying the locations of the monitors for the various monitoring networks operating in the CENRAP region during 2002.

Table C-1. Ambient monitoring data available in the CENRAP region during 2002.

Monitoring Network	Chemical Species Measured	Sampling Frequency; Duration
IMPROVE	Speciated PM _{2.5} and PM ₁₀	1 in 3 days; 24 hr
CASTNET	Speciated PM _{2.5} , Ozone	Hourly, Weekly; 1 hr, Week
SEARCH	24-hr PM ₂₅ (FRM Mass, OC, BC, SO ₄ , NO ₃ , NH ₄ , Elem.); 24-hr PM coarse (SO ₄ , NO ₃ , NH ₄ , elements); Hourly PM _{2.5} (Mass, SO ₄ , NO ₃ , NH ₄ , EC, TC); and Hourly gases (O ₃ , NO, NO ₂ , NO _y , HNO ₃ , SO ₂ , CO)	Daily, Hourly;
NADP	WSO ₄ , WNO ₃ , WNH ₄	Weekly
EPA-FRM	Only total fine mass (PM _{2.5})	1 in 3 days; 24 hr
EPA-STN	Speciated PM _{2.5}	Varies; Varies
AIRS/AQS	CO, NO, NO ₂ , NO _x , O ₃	Hourly; Hourly

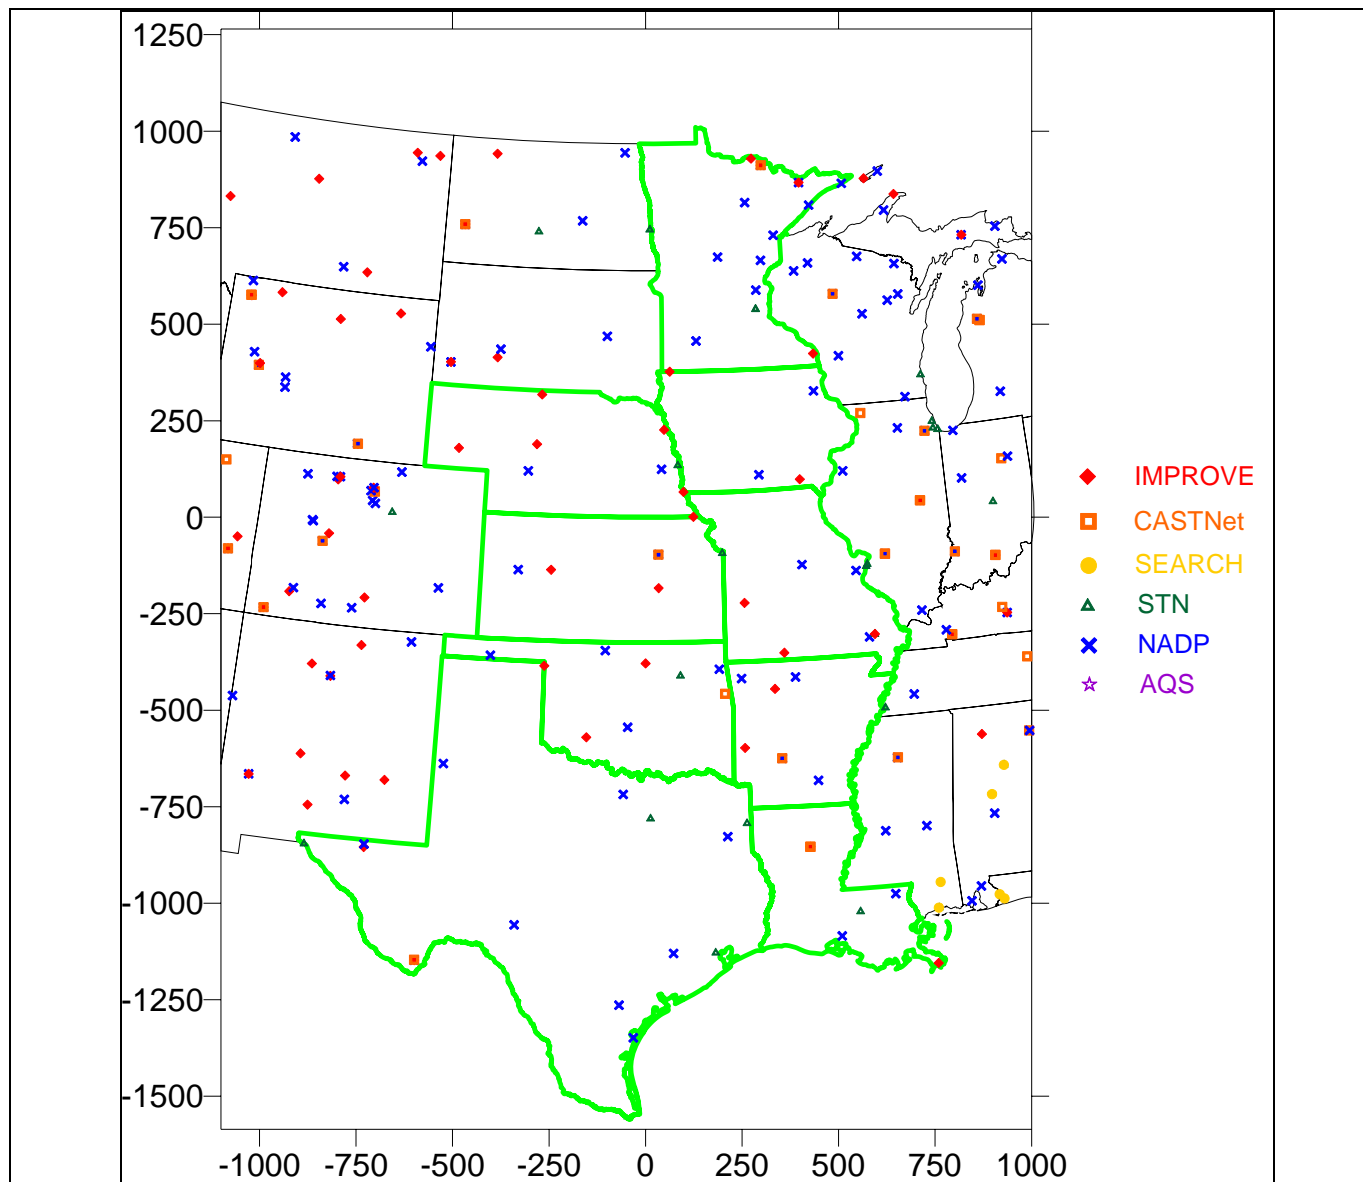

Figure C-3. Locations of surface monitors within the CENRAP states for sites operating during 2002.

C.2.2 Scope of CMAQ Model Performance Evaluation

The primary focus of the CMAQ Base F evaluation is on how well the model is able to replicate observed concentrations gas-phase pollutants and precursors, the various components of PM_{2.5}, total observed mass of PM_{2.5}, and wet deposition amounts. The CMAQ operational evaluation, model outputs are compared statistically and graphically with observational data obtained from the IMPROVE, CASTNet, STN, NADP and AQS monitoring networks. Because the SEARCH network is located in the southeastern U.S. (VISTAS region) outside of the CENRAP region, it is not a major component of our evaluation. Also, since the EPA-FRM network focuses on just PM_{2.5} mass measurements primarily in PM_{2.5} nonattainment or near nonattainment areas it is not very relevant for simulating regional haze at mainly remote Class I areas so is also not used in our model performance evaluation. The primary focus of the operational evaluation of the CMAQ 2002 Base F simulation is the performance of PM components in the CENRAP region for predicting regional haze at Class I areas.

Many statistical performance measures have been calculated using the different monitoring networks and across the different model performance subdomains (e.g., RPO regions). Table C-2 lists the definitions of the model performance evaluation statistical metrics. These performance metrics are routinely generate by the UCR Analysis Tool and are available on the project website. Many of them are measures of bias and error that are somewhat redundant.

Table C-2. Statistical Measures Used in the CENRAP CMAQ Model Evaluation.

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Accuracy of paired peak (A_p)	Paired_Peak	$\frac{P - O_{peak}}{O_{peak}}$	P_{peak} = paired (in both time and space) peak prediction
Coefficient of determination (r^2)	Coef_Determ	$\frac{\left[\sum_{i=1}^N (P_i - \bar{P})(O_i - \bar{O}) \right]^2}{\sum_{i=1}^N (P_i - \bar{P})^2 \sum_{i=1}^N (O_i - \bar{O})^2}$	P_i = prediction at time and location i ; O_i = observation at time and location i ; \bar{P} = arithmetic average of P_i , $i=1,2,\dots,N$; \bar{O} = arithmetic average of O_i , $i=1,2,\dots,N$
Normalized Mean Error (NME)	Norm_Mean_Err	$\frac{\sum_{i=1}^N P_i - O_i }{\sum_{i=1}^N O_i}$	Reported as %
Root Mean Square Error ($RMSE$)	Rt_Mean_Sqr_Err	$\left[\frac{1}{N} \sum_{i=1}^N (P_i - O_i)^2 \right]^{1/2}$	Reported as %
Fractional Gross Error (F_E)	Frac_Gross_Err	$\frac{2}{N} \sum_{i=1}^N \left \frac{P_i - O_i}{P_i + O_i} \right $	Reported as %
Mean Absolute Gross Error ($MAGE$)	Mean_Abs_G_Err	$\frac{1}{N} \sum_{i=1}^N P_i - O_i $	
Mean Normalized Gross Error ($MNGE$)	Mean_Norm_G_Err	$\frac{1}{N} \sum_{i=1}^N \frac{ P_i - O_i }{O_i}$	Reported as %
Mean Bias (MB)	Mean_Bias	$\frac{1}{N} \sum_{i=1}^N (P_i - O_i)$	Reported as concentration (e.g., $\mu\text{g}/\text{m}^3$)

Statistical Measure	Shorthand Notation	Mathematical Expression	Notes
Mean Normalized Bias (MNB)	Mean_Norm_Bias	$\frac{1}{N} \sum_{i=1}^N \frac{(P_i - O_i)}{O_i}$	Reported as %
Mean Fractionalized Bias (Fractional Bias, MFB)	Mean_Fract_Bias	$\frac{2}{N} \sum_{i=1}^N \left(\frac{P_i - O_i}{P_i + O_i} \right)$	Reported as %
Normalized Mean Bias (NMB)	Norm_Mean_Bias	$\frac{\sum_{i=1}^N (P_i - O_i)}{\sum_{i=1}^N O_i}$	Reported as %
Bias Factor (BF)	Bias Factor	$\frac{1}{N} \sum_{i=1}^N \left(\frac{P_i}{O_i} \right)$	Reported as BF:1 or 1: BF or in fractional notation (BF/1 or 1/BF).

C.2.3 Operational Model Evaluation Approach

The CENRAP modeling databases will be used to develop the visibility State Implementation Plan (SIP) due in December 2007 as required by the Regional Haze Rule (RHR). Accordingly, the primary focus of the operational evaluation is on the six components of fine particulate (PM_{2.5}) and Coarse Matter (PM_{2.5-10}) within the CENRAP region that are used to characterize visibility at Class I areas:

- Sulfate (SO₄);
- Particulate Nitrate (NO₃);
- Elemental Carbon (EC);
- Organic Mass Carbon (OMC);
- Other inorganic fine particulate (IP or Soil); and
- Coarse Matter (CM).

The model performance for ozone and precursor and product species (e.g., SO₂ and HNO₃) is also evaluated to build confidence that the modeling system is sufficiently reliable to project future-year visibility.

C.2.5 Performance Evaluation Tools

One of the many challenges in evaluating an annual PM/ozone model simulation is how to synthesize model performance given the sheer volume of output from an annual simulation. The model is run on a 148 x 112 x 19 grid with approximately 30 species producing hourly outputs for each day of the year. This results in approximately 90 trillion concentration estimates that are produced for an annual simulation. Thus, the synthesis and interpretation of numerous graphical and tabular displays of model performance into a few concise and descriptive displays that identify the most salient features of model performance is necessary. As part of the CENRAP modeling, as well as work performed by WRAP, VISTAS, MRPO and MANE-VU, several analysis tools and summary displays have been developed and are used:

UCR Analysis Tools: The University of California at Riverside (UCR) Analysis Tools have been used extensively to evaluate the CMAQ and CAMx models for CENRAP (e.g., Morris et al., 2005), WRAP (Tonnesen et al., 2004), VISTAS (Morris et al., 2004) as well as other studies and are run on a Linux platform separately for each network. Numerous graphical displays of model performance are automatically generated using gnuplot. The software generates the following summary and graphical displays of model performance:

- Tabular statistical measures (see Table C-2);
- Time Series Plots for each site and species; and
- Scatter Plots for each species by allsite_allday, allday_onesite and allsite_oneday.

The UCR Analysis Tool is run for a specific subregion (e.g., by RPO region) and for selected monitoring networks. Because each monitoring network has its own measurement artifacts, the model is evaluated separately for each monitoring network.

Summary Bias/Error Plots: The modeling team has developed additional displays of model performance statistics that elucidate model performance in a concise manner: (1) monthly time series plots of average bias and error; (2) soccer plots that display bias versus error and compares them to model performance goals and criteria; and (3) tools to analyze visibility model performance for the worst and best 20 percent visibility days that are used in visibility projections.

GA DNR Analysis Plots: Dr. James Boylan of the Georgia Department of Natural Resources has extended the concept in EPA's draft PM fine particulate and regional haze modeling guidance that model performance for species that make up a major contribution to visibility impairment be subjected to more stringent goals than species that are minor contributors by developing concentration-dependent performance goals and "Bugle Plots" to display them (Boylan, 2004).

The evaluation of the CENRAP 2002 36 km Base F CMAQ simulation used each of the analysis tools listed above taking advantage of their different descriptive and complimentary nature. The use of these analysis tools generated thousands of statistical measures and graphical displays of model performance that cannot all be displayed in this report. The modeling team has gone through the plots and measures using slide shows to identify those displays that are most descriptive in conveying model performance so should be included in this TSD. The complete set of model performance statistics and graphical performance displays can be found on the CENRAP modeling Website at:

http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml#cmaq_typ02f_mpe

Note that model performance statistics are calculated separately for each of the monitoring networks. Different PM measurement technology can produce different measurement values even when measuring the same air parcel. Thus, when calculating model performance metrics, measurements in different networks are not mixed.

C.2.4 Subdomains Analyzed

CENRAP has been analyzing model performance in five subdomains corresponding to the states contained in the five RPOs (see Figure 1-1):

- CENRAP
- MRPO
- VISTAS
- MANE-VU
- WRAP

As CENRAP has refined its emissions inventory, the changes in model performance from one 2002 base case to another has diminished to the point where little has changed in the last few iterations. Thus, the CMAQ 2002 36 km Base F evaluation presented in this section was just performed for the CENRAP region and the reader is referred to the modeling Website (<http://pah.cert.ucr.edu/aqm/cenrap/cmaq.shtml>) and Morris and co-workers (2005) for the evaluation outside of the CENRAP region and the diagnostic model evaluation.

C.2.5 Model Performance Goals and Criteria

The issue of model performance goals for PM species is an area of ongoing research and debate. For ozone modeling, EPA has established performance goals for 1-hour ozone normalized mean bias and gross error of $\pm 15\%$ and $\pm 35\%$, respectively (EPA, 1991). EPA's draft fine particulate modeling guidance notes that performance goals for ozone should be viewed as upper bounds of model performance that PM models may not be able to always achieve and we should demand better model performance for PM components that make up a larger fraction of the PM mass than those that are minor contributors (EPA, 2001). EPA's final modeling guidance does not list any specific model performance goals for PM and visibility modeling and instead provides a summary of PM model performance across several historical applications that can be used for comparisons if desired. Measuring PM species is not as precise as ozone monitoring. In fact, the differences in measurement techniques for some species likely exceed the more stringent performance goals, such as those for ozone. For example, recent comparisons of the PM species measurements using the IMPROVE and STN measurement technologies found differences of approximately $\pm 20\%$ (SO₄) to $\pm 50\%$ (EC) (Solomon et al., 2004).

For the CENRAP, VISTAS and WRAP modeling we have adopted three levels of model performance goals and criteria for bias and gross error as listed in Table C-3. Note that we are not suggesting that these performance goals be adopted as guidance or that they are the most appropriate goals to use. Rather, we are just using them to frame and put the PM model performance into context and to facilitate model performance intercomparison across episodes, species, models and sensitivity tests.

Table C-3. Model performance goals and criteria used to assist in interpreting modeling results.

Fractional Bias	Fractional Error	Comment
#∇15%	#35%	Ozone model performance goal for which PM model performance would be considered good – note that for many PM species measurement uncertainties may exceed this goal.
#∇30%	#50%	Proposed PM model performance goal that we would hope each PM species could meet
#∇60%	#75%	Proposed PM criteria above which indicates potential fundamental problems with the modeling system.

As noted in EPA’s PM modeling guidance, less abundant PM species should have less stringent performance goals (EPA, 2001; 2007). Accordingly, we are also using performance goals that are a continuous function of average concentrations, as proposed by Dr. James Boylan at the Georgia Department of Natural Resources (GA DNR), that have the following features (Boylan, 2004):

- Asymptotically approaching proposed performance goals or criteria (i.e., the ∇30%/50% and ∇60%/75% bias/error levels listed in Table C-1) when the mean of the observed concentrations are greater than 2.5 ug/m³.
- Approaching 200% error and ∇200% bias when the mean of the observed concentrations are extremely small.

Bias and error are plotted as a function of average concentrations. As the mean concentration approach zero, the bias performance goal and criteria flare out to ∇200% creating a horn shape, hence the name “Bugle Plots”. Dr. Boylan has defined three Zones of model performance: Zone 1 meets the ∇30%/50% bias/error performance goal and is considered “good” model performance; Zone 2 lies between the ∇30%/50% performance goal and ∇60%/75% performance criteria and is an area where concern for model performance is raised; and Zone 3 lies above the ∇60%/75% performance criteria and is an area of questionable model performance.

C.2.6 Performance Time Periods

The CMAQ 2002 36 km Base F evaluation, model performance statistics and graphical displays are generated monthly using the native averaging times of each monitoring network (i.e., 24-hour for IMPROVE and STN; weekly for CASTNet and NADP; and hourly for AQS). As the focus of the RHR is on daily average visibility that is calculated from daily average PM species concentrations then the evaluation of the model for 24-hour concentrations is particularly relevant. The RHR places particular emphasis on the Worst 20% (W20%) and Best 20% (B20%) days at Class I areas. Thus, we also place particular emphasis on the model performance for PM species on the W20% and B20% days during 2002 at Class I areas.

C.2.7 Key Measures of Model Performance

Although we have generated numerous statistical performance measures (see Table C-2) that are available on the CENRAP modeling website, when comparing model performance across months, subdomains, networks, grid resolution, models, studies, etc. it is useful to have a few key measurement statistics to be used to facilitate the comparisons. It is also useful to have a subset of the 2002 year that can represent the entire year so that a more focused evaluation can be conducted. We have found that the Mean Fractional Bias and Mean Fractional Gross Error appear to be the most consistent descriptive measure of model performance (Morris et al., 2004b; 2005). The Fractional Bias and Error normalize by the average of the observed and predicted value (see Table C-2) because it provides descriptive power across different magnitudes of the model and observed concentrations and is bounded by -200% to +200%. This is in contrast to the normalized bias and error (as recommended for ozone performance goals, EPA, 1991) that is normalized by just the observed value so can “blow up” to infinity as the observed value approaches zero. Below we perform a focused evaluation of model performance for four months of the 2002 year that are used to represent the seasonal variation in performance:

- January
- April
- July
- October

We also present fractional bias and error for all months of 2002 using time series and bugle plots.

C.3 Operational Model Performance Evaluation in the CENRAP Region

In the following discussions we use selected monthly scatter plots, time series plots and model performance statistical measures from the UCR Analysis Tools application to the 2002 CMAQ Base F base case simulation in an operational evaluation of the model for PM species. We focus on the six main components of PM that are used to project visibility.

C.3.1 Sulfate (SO₄) Monthly Model Performance

C.3.1.1 SO₄ in January 2002

Figure C-4a displays scatter plots of predicted and observed SO₄ concentrations or wet depositions for sites in the CENRAP regions using observations from the IMPROVE, STN, CASTNet and NADP monitoring networks; the IMPROVE and STN SO₄ concentrations are 24-hour averages whereas the CASTNet SO₄ concentrations and NADP SO₄ wet deposition are weekly averages. The January SO₄ performance at the IMPROVE and STN networks in the CENRAP region is quite good with low fractional bias (-12% to -13%) and some scatter (fractional error of 42% and 34%) but centered in the 1:1 line of perfect agreement. There is a net SO₄ underestimation bias in January across the CASTNet network (fractional bias of -34%) with wet SO₄ deposition overstated on average across the NADP sites in the CENRAP region (+40% fractional bias). Whether the overstated SO₄ wet deposition is a contributor to the SO₄ concentration underestimation bias is unclear, but it is in the correct direction to account for it.

The time series comparisons of predicted and observed 24-hour SO₄ concentrations at CENRAP Class I area IMPROVE sites during January 2002 shown in Figure C-4b are quite encouraging. Although there are some days and sites with mismatches (e.g., January 26 at BOWA and VOYA) and sites with systematic performance problems (SO₄ underestimated at BIBE), the time series in general are quite good with the model tracking the observed temporal variation in daily sulfate in January and some sites exhibiting remarkable agreement (e.g., MING).

Figure C-4c displays the spatial variations in the predicted and IMPROVE observed SO₄ concentrations for January 20, 23, 26 and 29, 2002, which are four consecutive days of IMPROVE monitoring using its 1:3 day monitoring frequency. On January 20 both the model and observations agree on that an elevated sulfate cloud is entering the CENRAP region across southern Illinois and Missouri. There is a sharp SO₄ concentration gradient going east to west with both the model and observations estimating relatively clean SO₄ values over Colorado. By January 23 the model and observations agree that elevated SO₄ exists along a diagonal orientation from Chicago to East Texas. Although there are some SO₄ model/observed spatial mismatches on this day (e.g., northern Louisiana and western Arkansas) the model generally reproduces the areas of elevated and low observed SO₄. By January 29 the model and observations agree that SO₄ has cleaned out of the CENRAP region. Although there are elevated SO₄ observations in western North Dakota and northern Minnesota not reflected in the model. On January 29 there is an elevated tongue of SO₃ entering the CENRAP region through southern Illinois stretching to the southwest almost to Big Bend in western Texas. Observed SO₄ is measured at Big Bend but the modeled high SO₄ is slightly east of there. There is very good agreement on this day between the predicted and observed spatial distribution of SO₄.

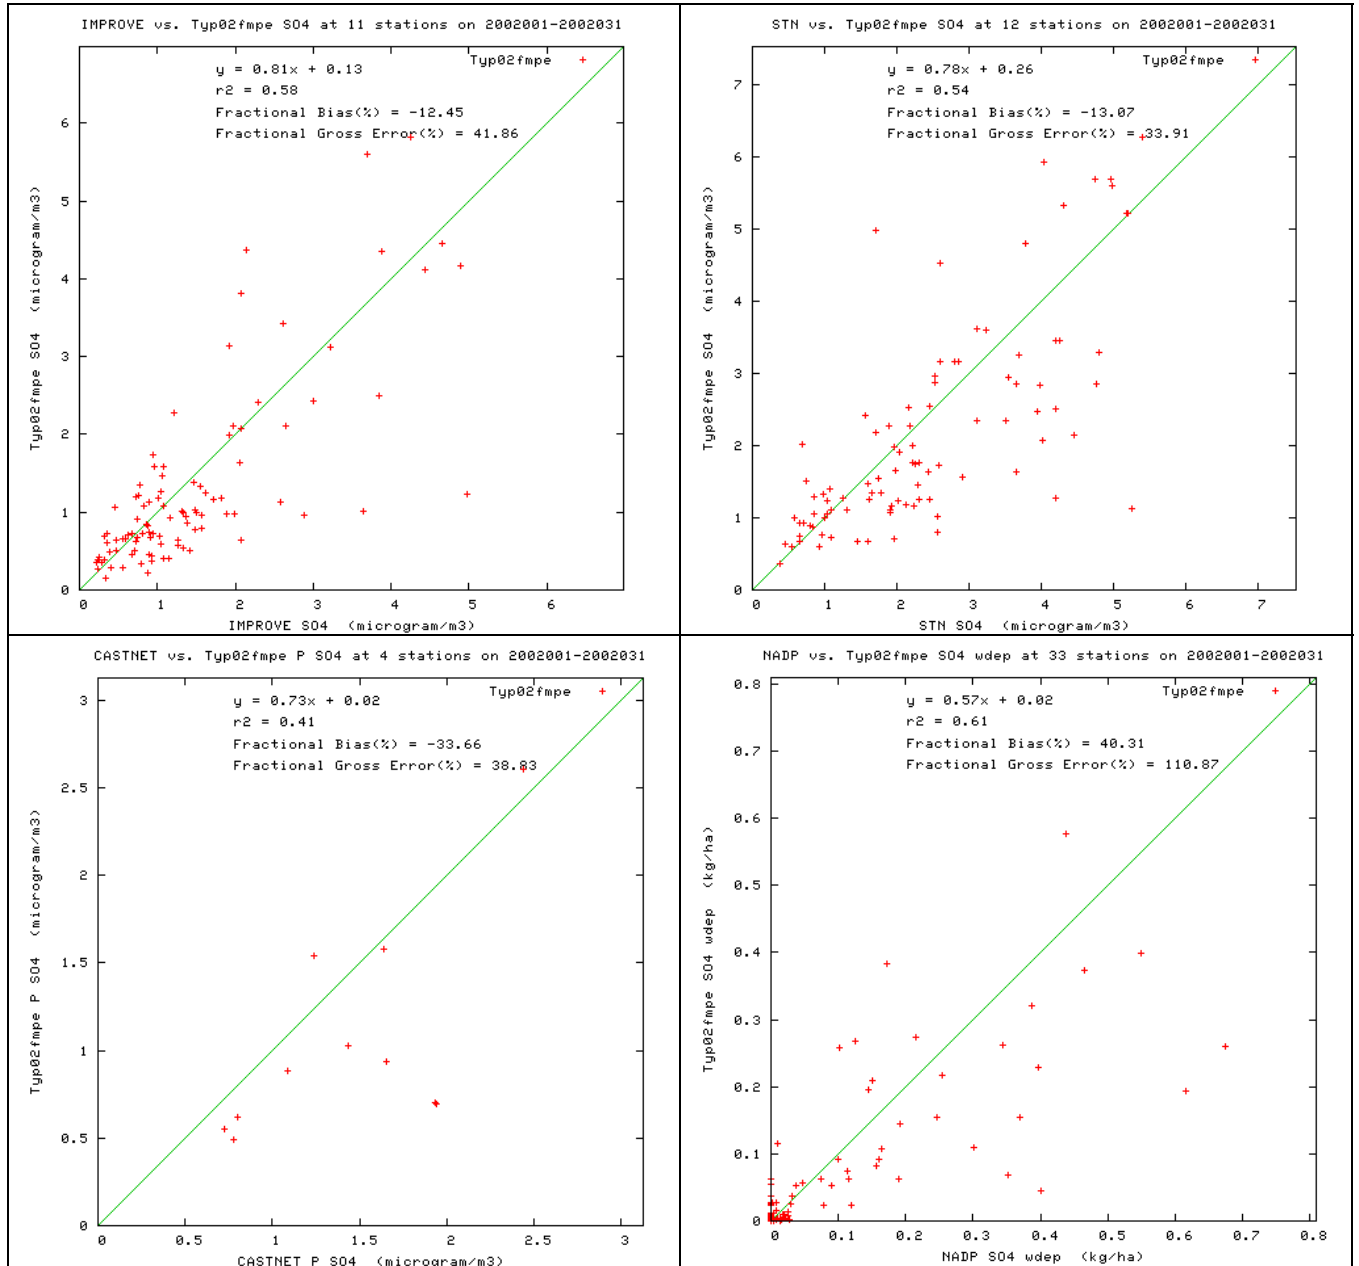

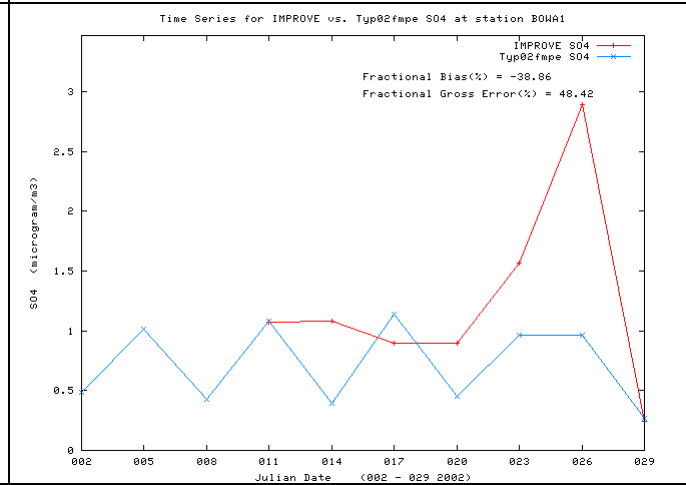

Figure C-4a. Scatter plots of predicted and observed sulfate (SO4) concentrations for January 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

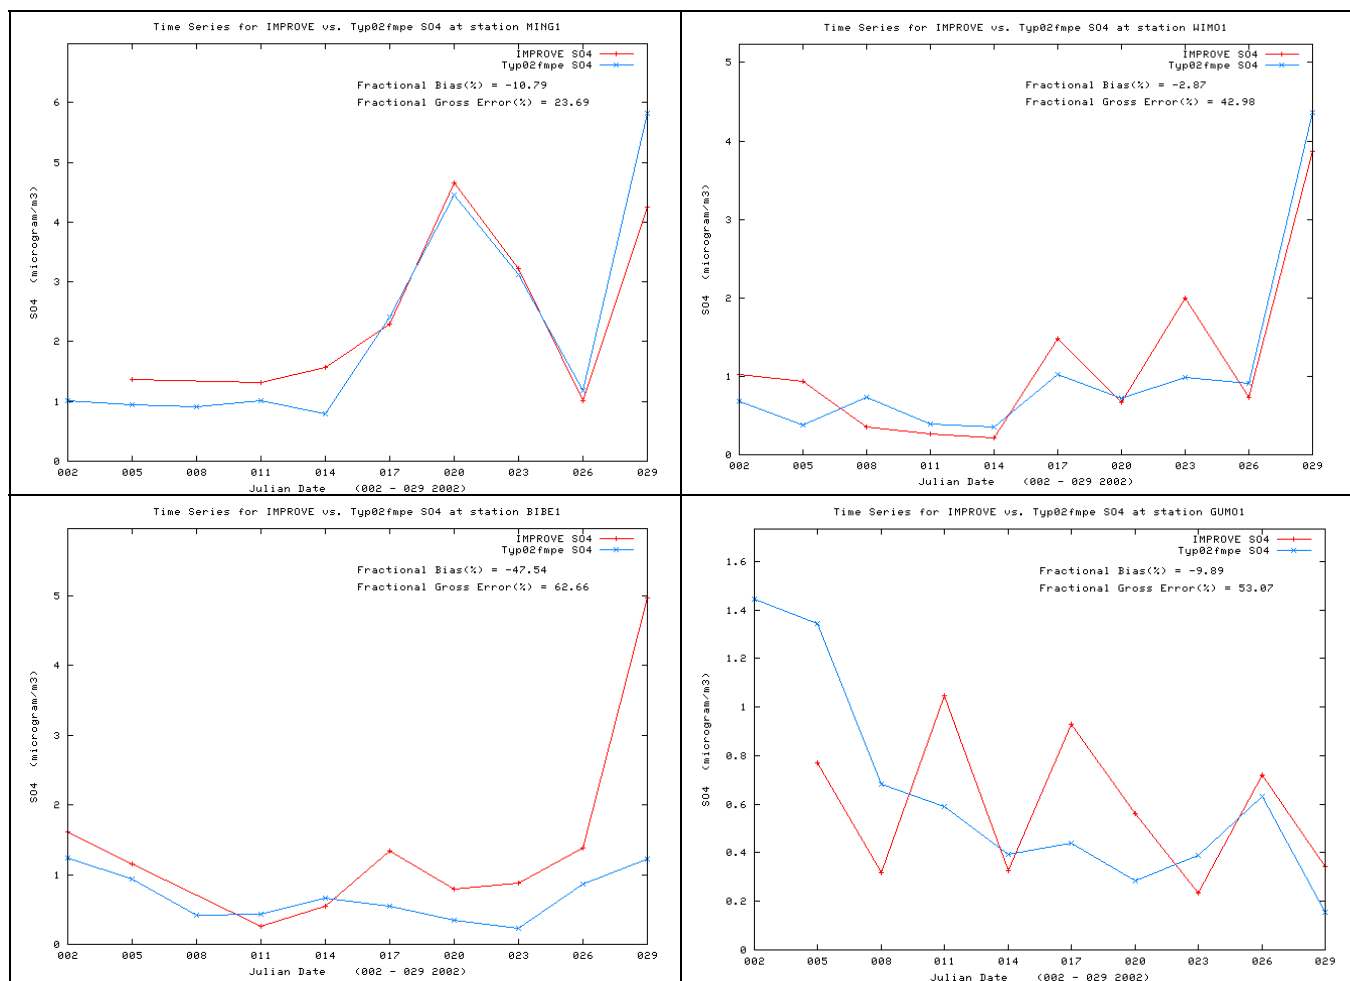

Figure C-4b. Time series of predicted and observed 24-hour sulfate (SO₄) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

Figure C-4c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour SO4 concentrations for January 20, 23, 26 and 29, 2002.

C.3.1.2 SO₄ in April 2002

In April CMAQ underestimates the observed SO₄ in the CENRAP region with fractional bias values of -52%, -30% and -58% across the IMPROVE, STN and CASTNet networks (Figure C-5a). The fractional bias for wet SO₄ deposition is quite low (3%) albeit with a lot of scatter which is reflected in high fractional error (78%). The ability of the model to reproduce the temporal variability of the April observed SO₄ concentrations at the IMPROVE sites is quite variable. The SO₄ under-prediction bias is clearly present at several sites (e.g., HEGL, BIBE and GUMO), whereas there is quite good agreement at others (UPBU, BRET and VOYA). Comparisons of the spatial distributions of the predicted and observed SO₄ concentrations on April 5, 8, 11 and 14 are shown in Figure C-5c. On April 5 the model reproduces the half circle of elevated SO₄ across Texas-Louisiana, but appears to not be as large an area as observed coming up short from some of the sites (e.g., BIBE and GUMO). Model and observations agree that April 8 is a relatively low SO₄ day in the CENRAP region with just a small intrusion of elevated values across Mississippi. On April 14 the model has two separate clouds of elevated SO₄, one over East Texas-Louisiana and one over northeastern Illinois and eastward with a clean area in between in southern Missouri. The observations agree except that it has these two elevated SO₄ areas connected with the southern Missouri area not as clean as in the model.

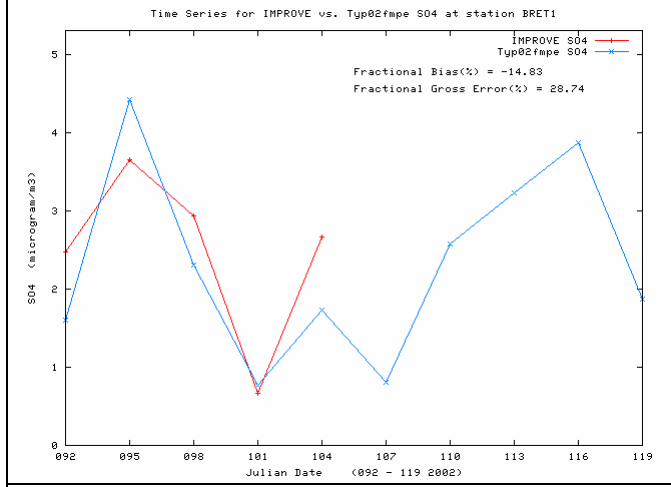

Figure C-5a. Scatter plots of predicted and observed sulfate (SO4) concentrations for April 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-5b. Time series of predicted and observed 24-hour sulfate (SO4) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.1.3 SO₄ in July 2002

SO₄ concentrations are also underestimated by CMAQ in July (Figure C-6a) with fractional bias value ranging from -22 to -52%. Wet SO₄ deposition is slightly overstated (22%) with a lot of scatter (83% error). The July SO₄ under-prediction bias is also reflected in the time series plots (Figure C-6b). Comparisons of the predicted and observed spatial distribution of SO₄ in the CENRAP region for July 7, 10, 13 and 16, 2002 are shown in Figure C-6c. In general the model and observations agree on the locations of the elevated SO₄, except that the observed extent is somewhat larger so that the modeled elevated SO₄ fails to impact some of the sites on the edge of the elevated cloud of SO₄ (e.g., Big Bend, Guadalupe Mountains and northwestern Oklahoma).

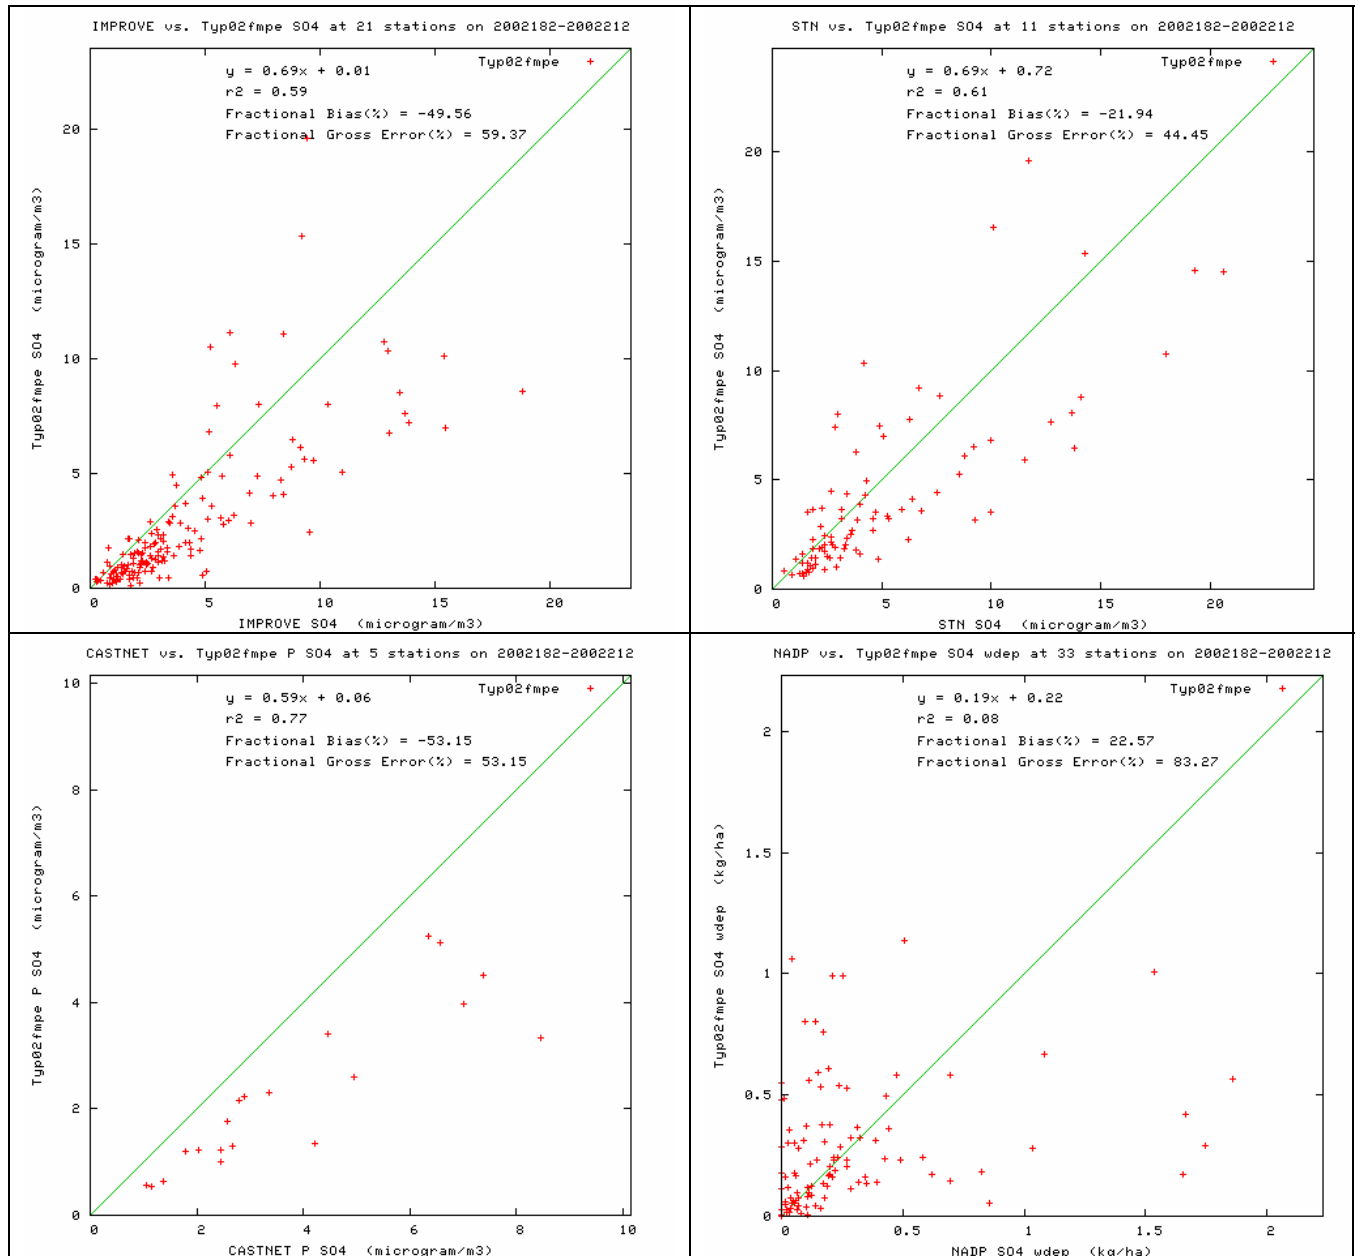

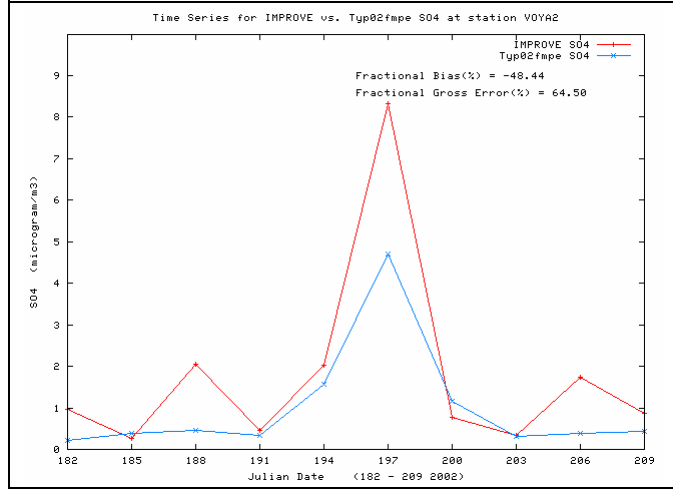

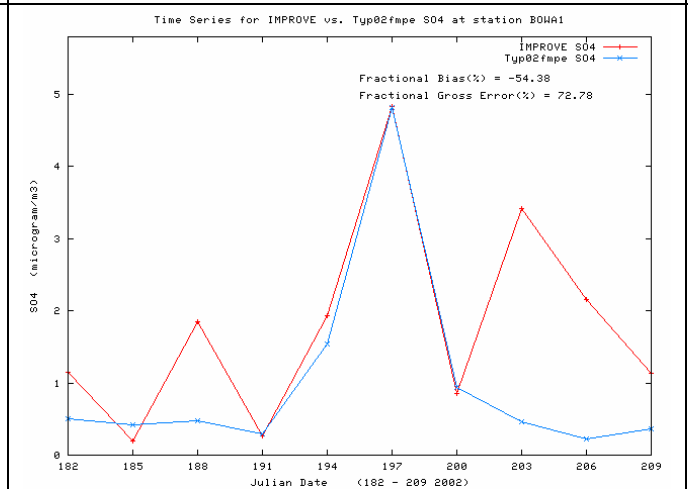

Figure C-6a. Scatter plots of predicted and observed sulfate (SO₄) concentrations for July 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-6b. Time series of predicted and observed 24-hour sulfate (SO₄) concentrations at CENRAP IMPROVE CLASS I AREA sites in July 2002 for CMAQ 2002 36 km Base F base case simulation.

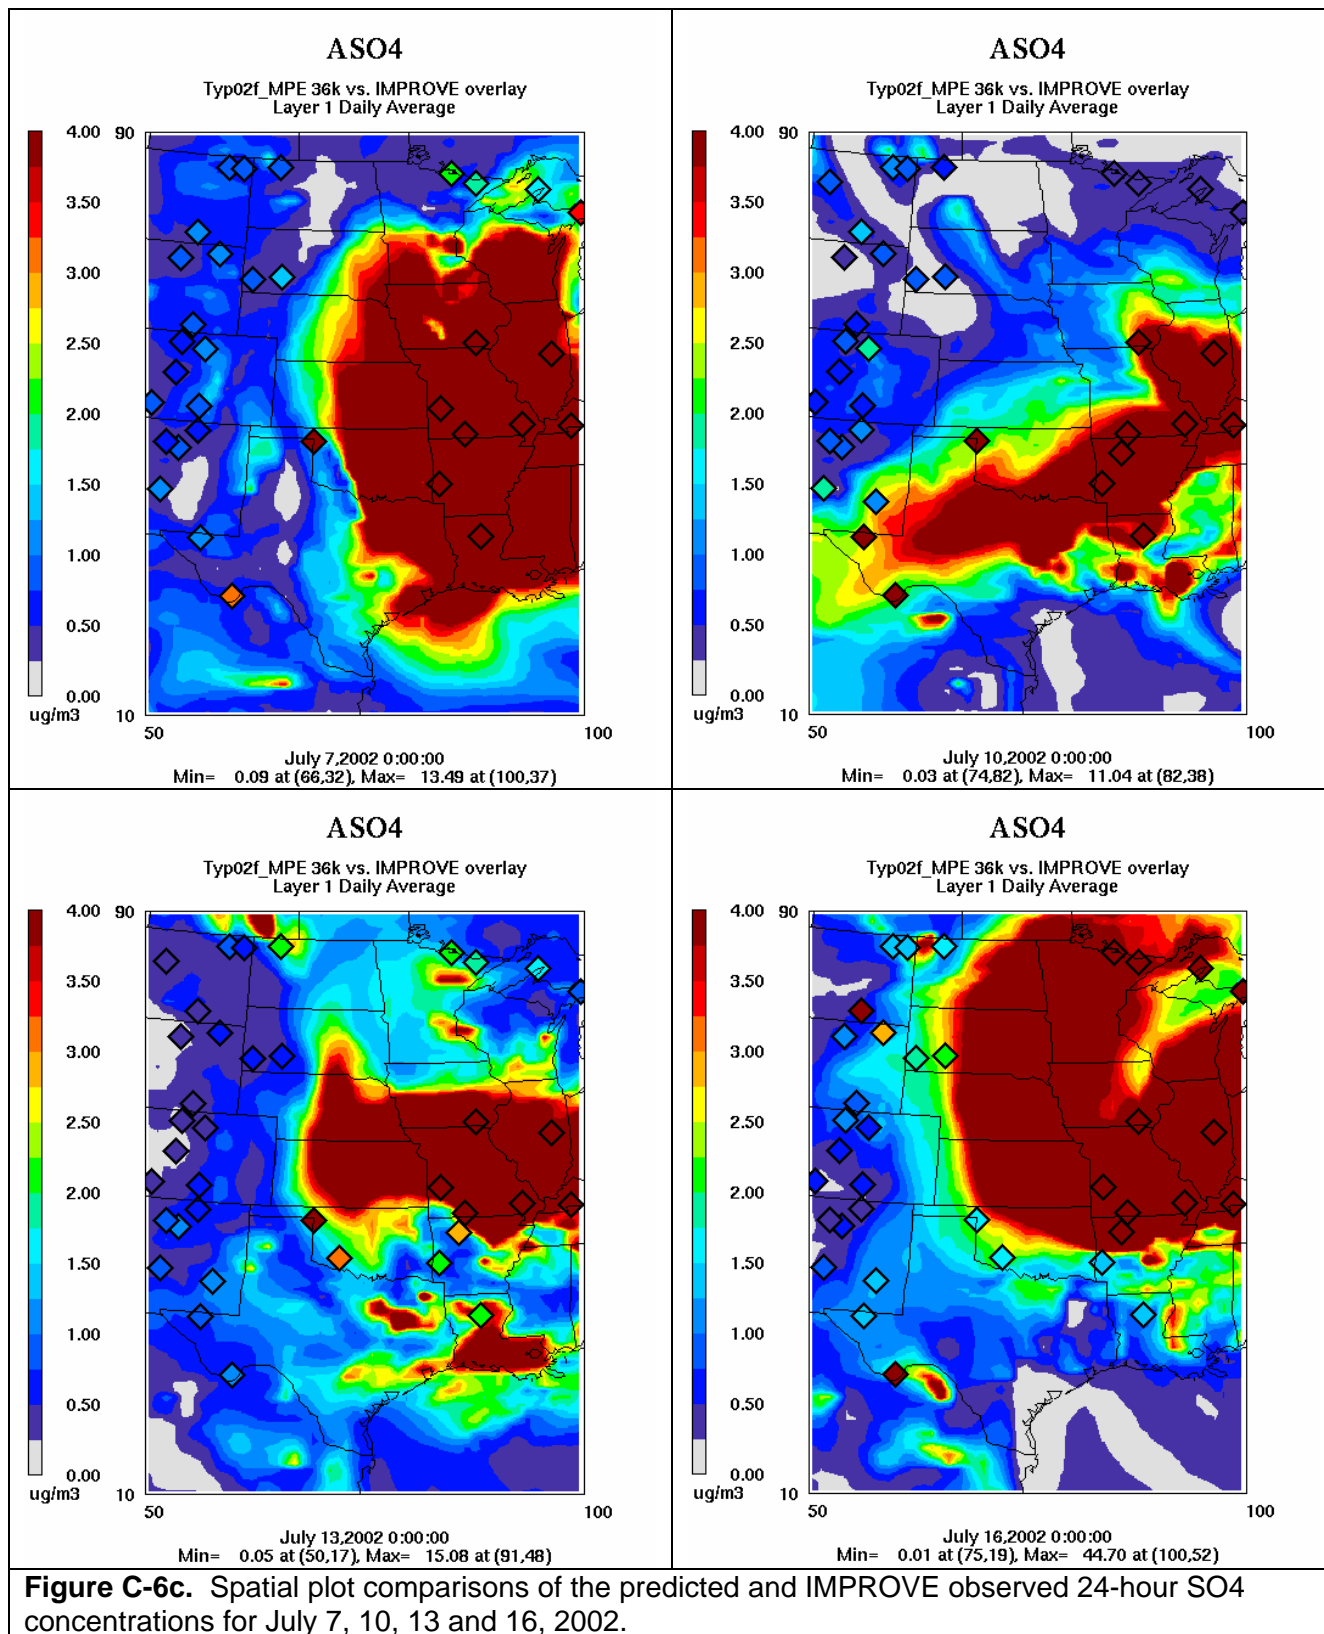

Figure C-6c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour SO4 concentrations for July 7, 10, 13 and 16, 2002.

C.3.1.4 SO4 in October 2002

In October 2002, CMAQ is doing a better job of reproducing the observed SO4 concentrations with much lower fractional bias values (-6%, 0% and -23%) and fractional errors < 40% (Figure C-7a). The observed SO4 time series are also reproduced well by the model, although an under-prediction bias is clearly evident at Big Bend, Guadalupe Mountains and Wichita Mountains. The model also reproduces the observed spatial distribution of SO4 well in October (Figure C-7c).

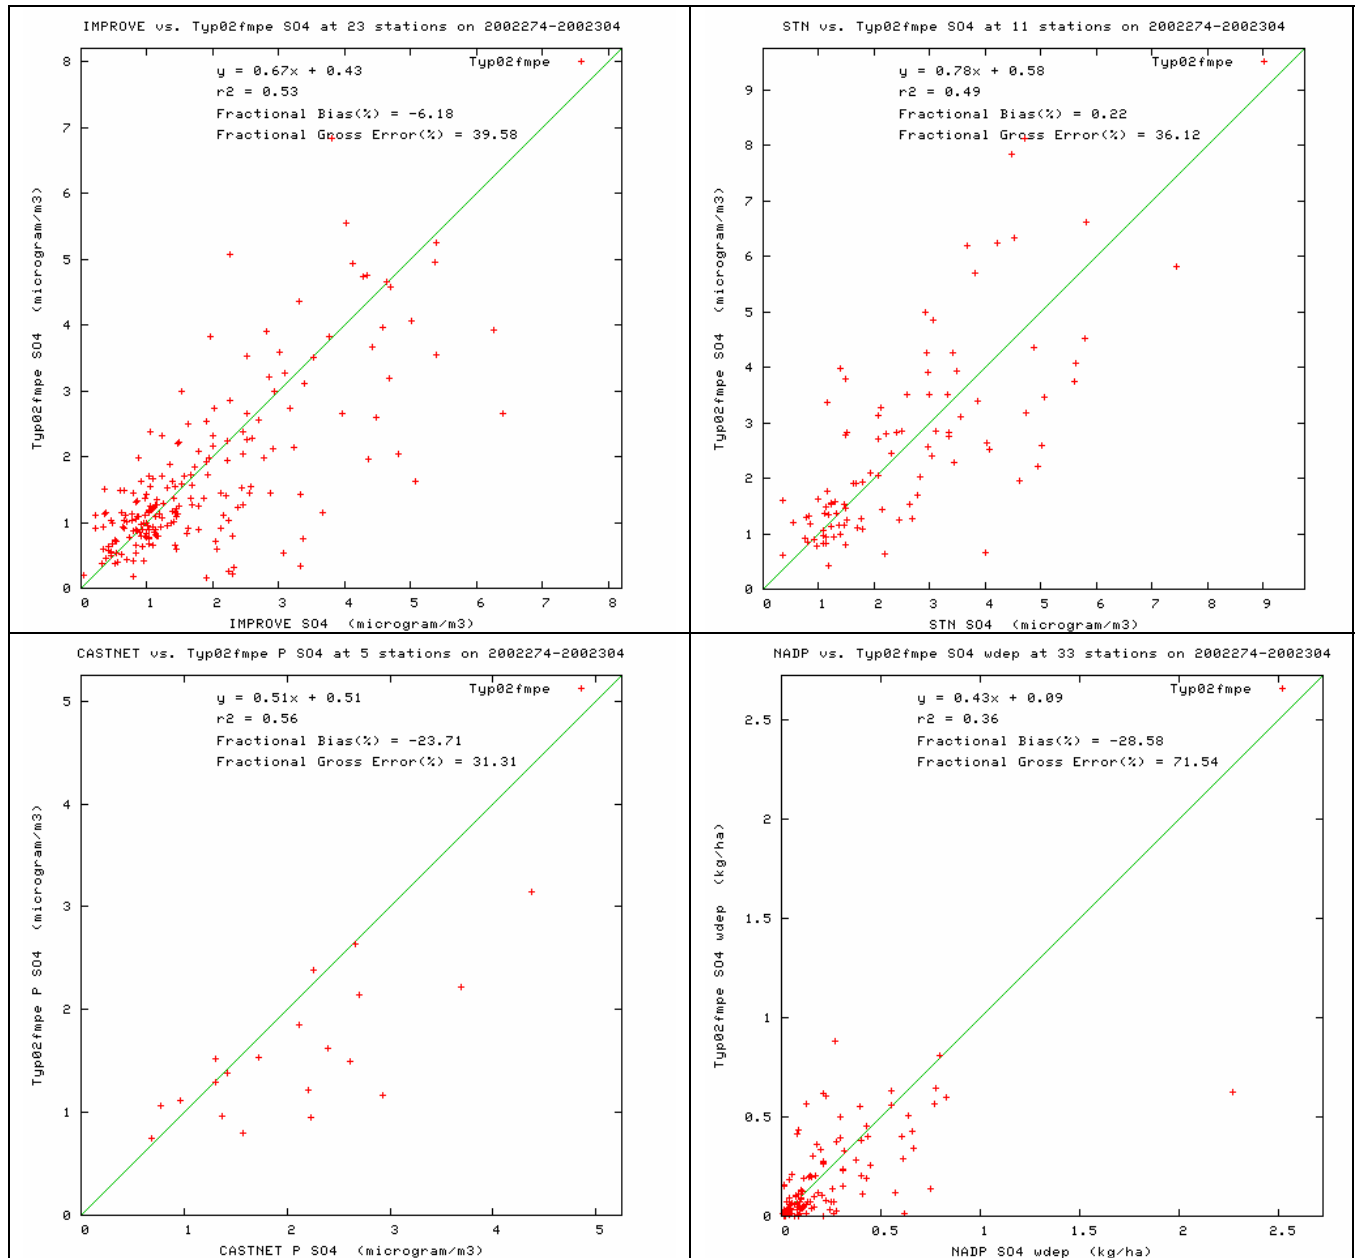

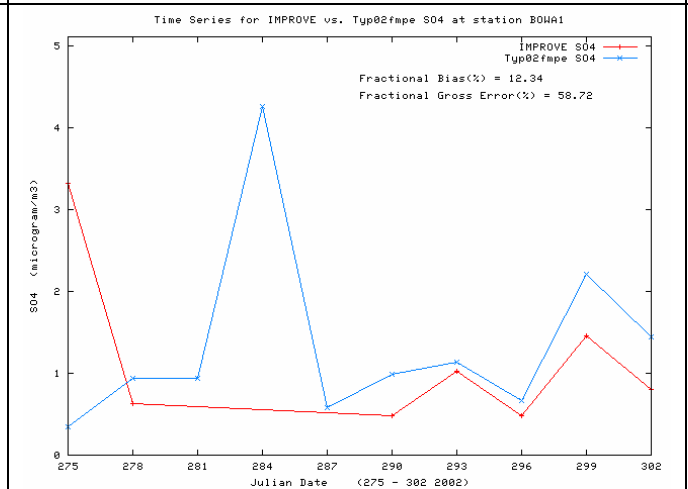

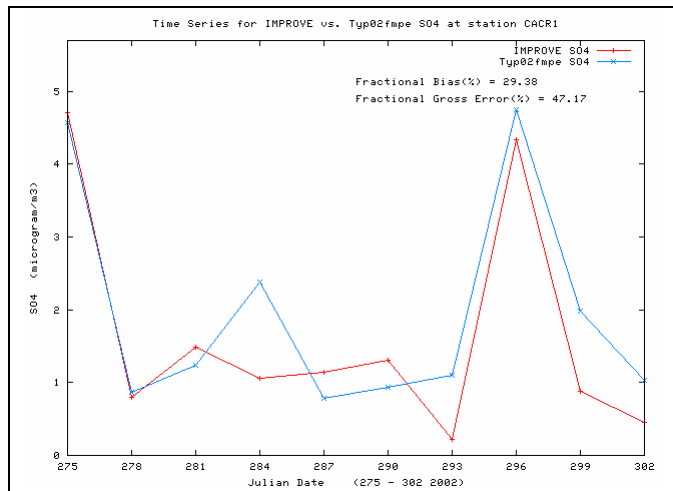

Figure C-7a. Scatter plots of predicted and observed sulfate (SO4) concentrations for October 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-7b. Time series of predicted and observed 24-hour sulfate (SO₄) concentrations at CENRAP IMPROVE CLASS I AREA sites in October 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.1.5 SO₄ Monthly Bias and Error

Figure C-8 compares the monthly SO₄ fractional bias and error across the CENRAP region for the three monitoring networks. The under-prediction bias is clearly evident the first 8-10 months of the year. This underestimation bias is greatest across the CASTNet network which persists through out the year and is least for the STN network where it disappears by August-September. The monthly SO₄ fractional errors are generally between 30% and 60% and are greatest in the summer when SO₄ concentrations are the highest.

Figure C-9 presents a Bugle Plot of monthly So₄ fractional bias and error statistics and compares them against the proposed PM model performance goal and criteria (see Table C-3). For the STN network, it appears that SO₄ performance for all months achieves the proposed PM model performance goal. For the IMPROVE network, approximately half of the months achieve the proposed PM performance goal with the other half exceed the goal but within the performance criteria. Across the CASTNet network most months exceed the proposed goal and are within the criteria. Although the CASTNet fractional bias for some months is right at the criteria ($\leq \pm 60\%$). With the exception of two IMPROVE months, all of the monthly SO₄ fractional error performance statistics achieve the proposed PM model performance goal.

C.3.2 Nitrate (NO₃) Monthly Model Performance

The following sections discuss the monthly NO₃ model performance across the IMPROVE, STN and CASTNet monitoring networks in the CENRAP region.

C.3.2.1 NO₃ in January 2002

January NO₃ CMAQ model performance is characterized by an overestimation bias across the CENRAP region (Figure C-10a). The fractional bias values for the IMPROVE, STN and CASTNet networks are 38%, 29% and 61%. Unlike SO₄, wet deposition of NO₃ is also overstated in January (43%). Fractional errors range from 90%-100% for the IMPROVE and CASTNet networks and are lower (54%) for the STN network and higher (114%) for the NADP network.

With the exception of Breton Island and Big Bend, the model NO₃ over-prediction bias occurs at the other 8 CENRAP Class I areas (Figure C-10b). The observed time series is reproduced reasonable well at a couple sites, such as Wichita Mountains and the first half of January for Voyageurs. However, for most sites the observed NO₃ time series is not reproduced very well and is extremely poorly reproduced for Breton Island, Big Bend and Guadalupe Mountains.

The model typically estimates a larger area of elevated NO₃ concentrations than is observed. This is shown for January 20, 23, 26 and 29 in Figure C-10c. Whereas the model exhibits large areas of brown indicated daily average NO₃ concentrations of 4 µg/m³ or higher, the observed values of this high rarely occur and are usually limited to the central Illinois site. On January 20 the model estimates the entire eastern half of the CENRAP region should be covered by elevated NO₃ concentrations, whereas the observations indicate much lower values. On January 23 the modeled elevated NO₃ concentrations lies between the IMPROVE monitoring sites, although the central Illinois site suggests high NO₃ did occur in the region. The observations on January 26 also suggest lower NO₃ than the model is predicting. On January 29 the model estimates elevated NO₃ from the central Illinois site to Wichita Mountains, Oklahoma that is supported by these two observations. In general, the model is estimating more wide-spread elevated NO₃ concentrations than observed, whereas the observations suggest that the elevated NO₃ occurrences is less frequent and more spotty.

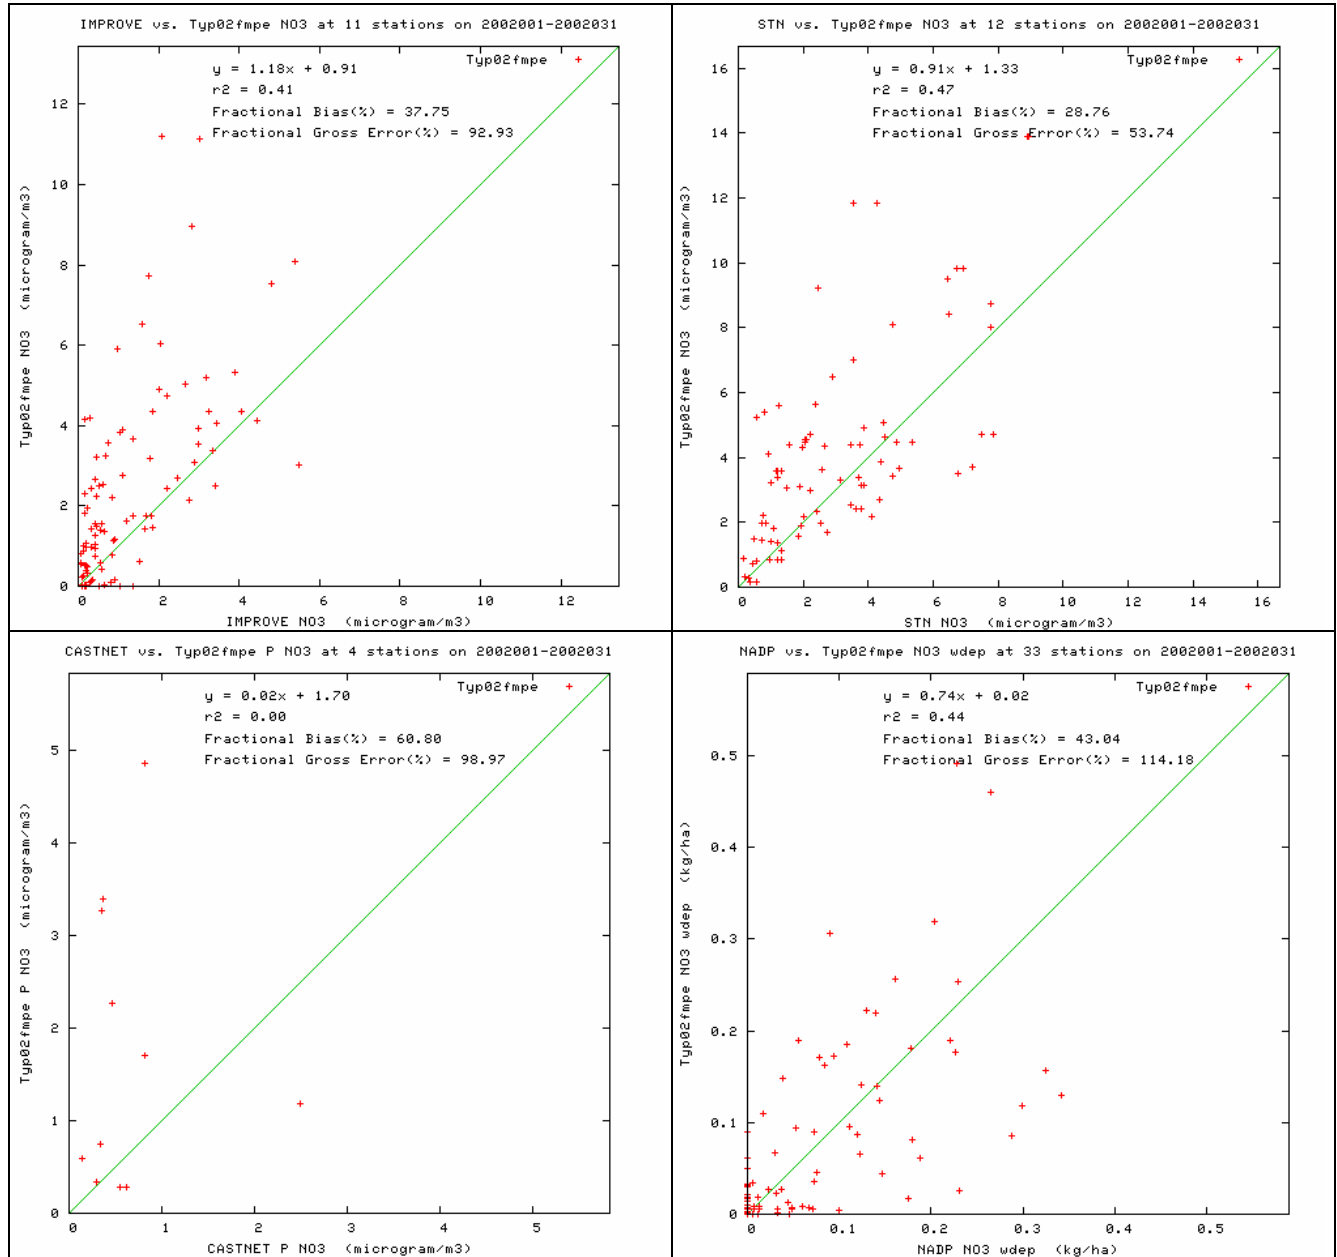

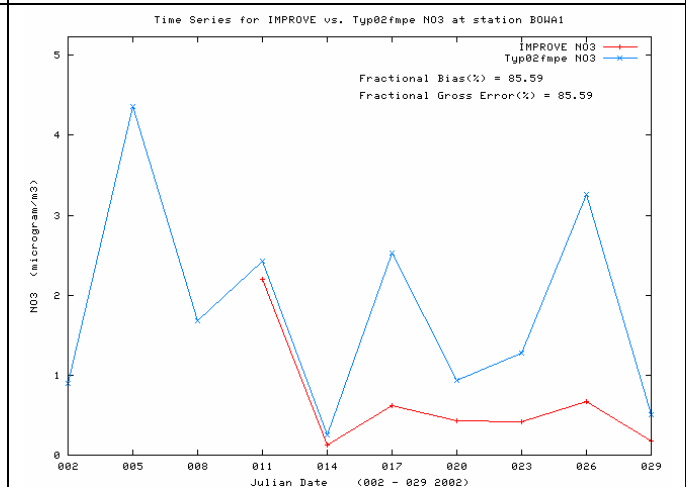

Figure C-10a. Scatter plots of predicted and observed nitrate (NO₃) concentrations for January 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

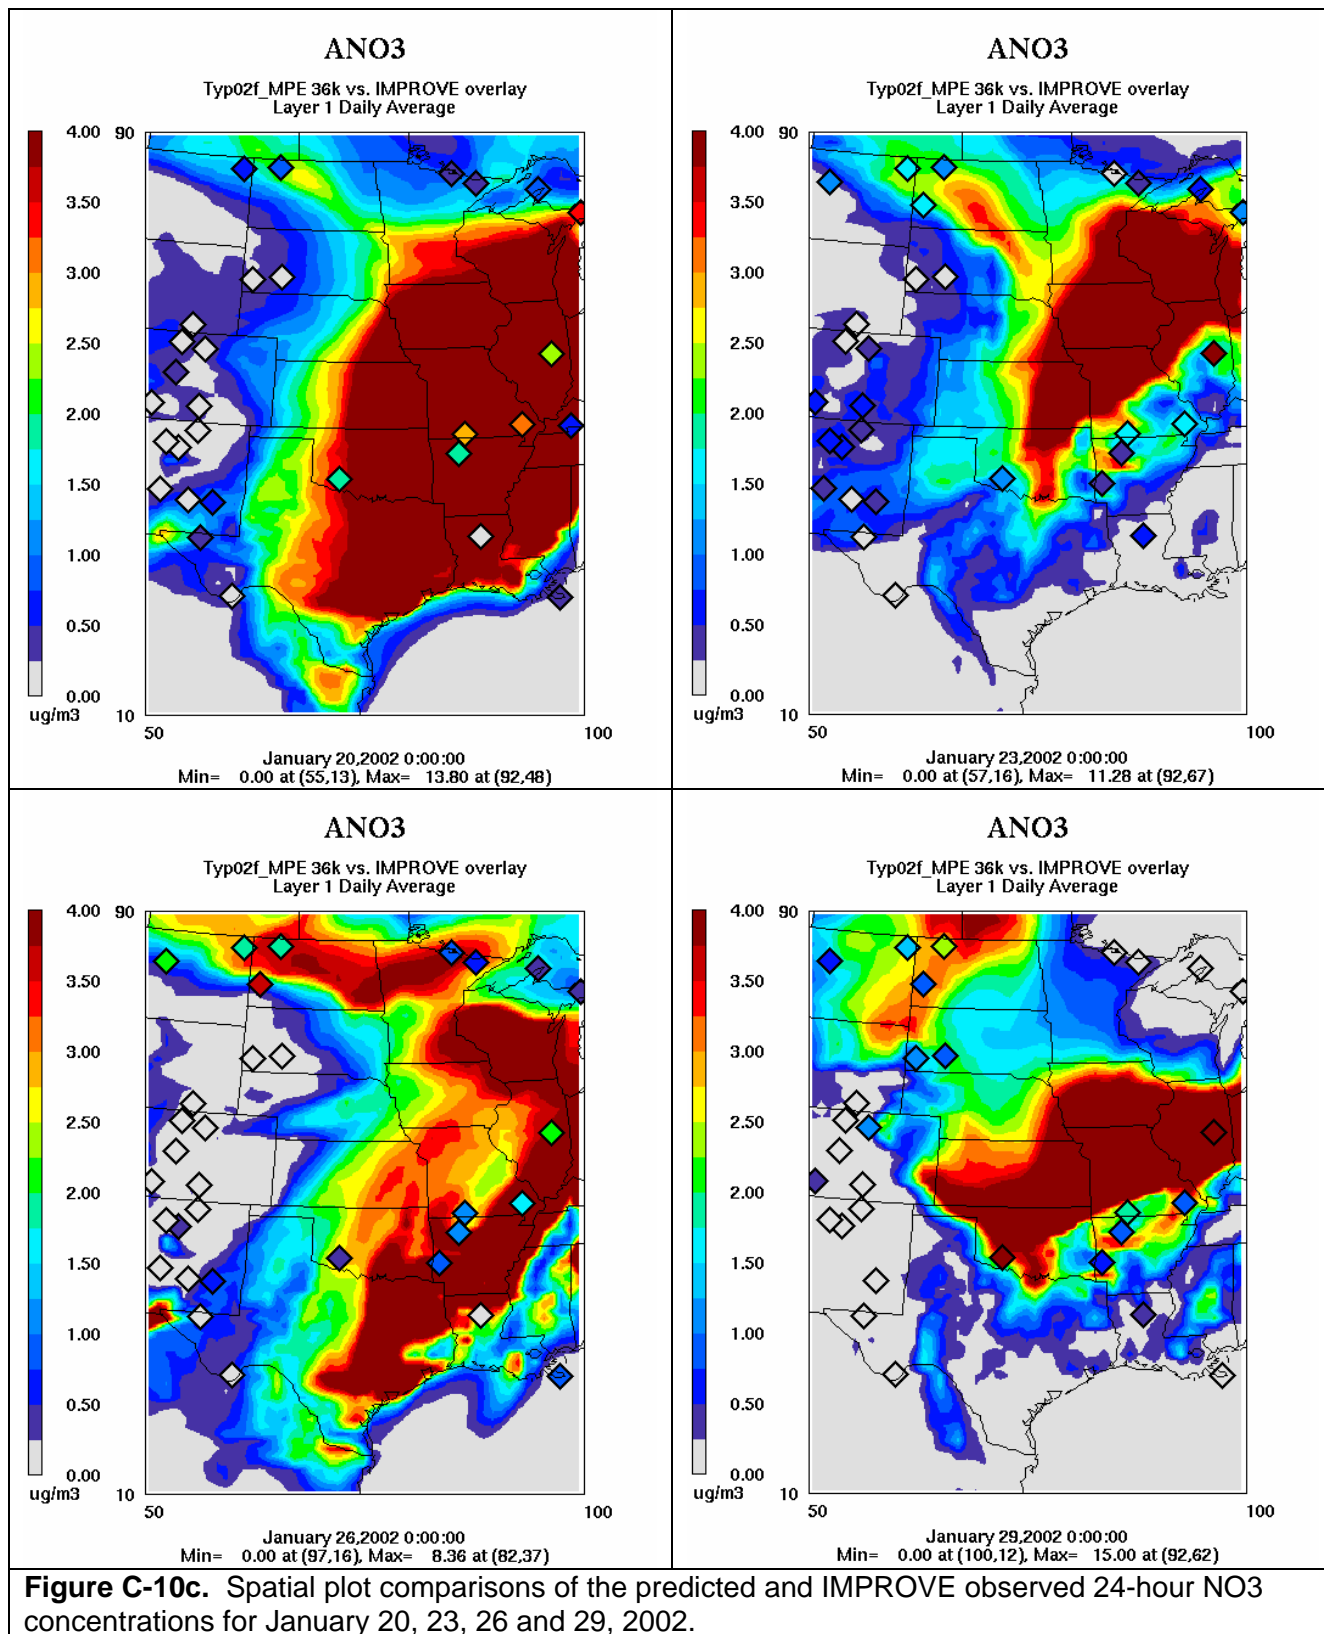

Figure C-10b. Time series of predicted and observed 24-hour nitrate (NO₃) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.2.2 NO₃ in April 2002

Unlike the NO₃ overestimation bias of January, the April NO₃ performance is characterized by an underestimation bias (Figure C-11a). This under-prediction bias appears to be driven by near zero model predictions when the observed values are small ($< 1 \mu\text{g}/\text{m}^3$), but positive. This effect is especially noticeable in the NO₃ time series (Figure C-11b) where at several sites the modeled NO₃ concentrations goes to zero (e.g., BRET, BIBE, GUMO), whereas the observed values has an approximately 0.2 $\mu\text{g}/\text{m}^3$ floor. The spatial maps suggest that the large April NO₃ under-prediction bias indicated by the performance statistics is not as bad as they suggest (Figure C-11c). Mostly the model is predicting low NO₃ values where low values are observed, just that the model approaches zero which results in a large relative difference with the observe values.

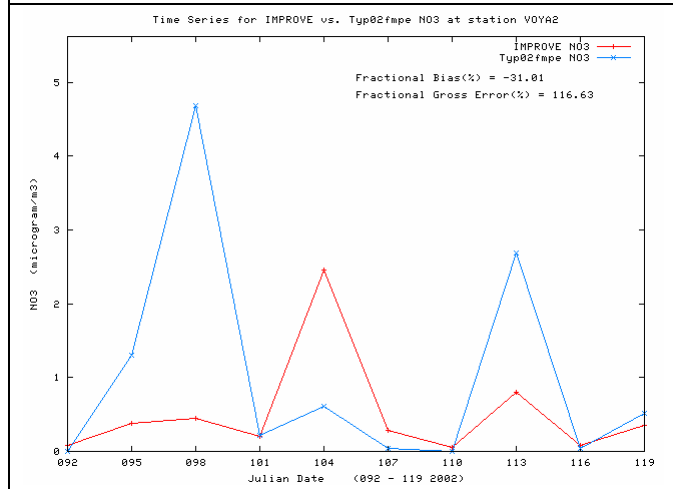

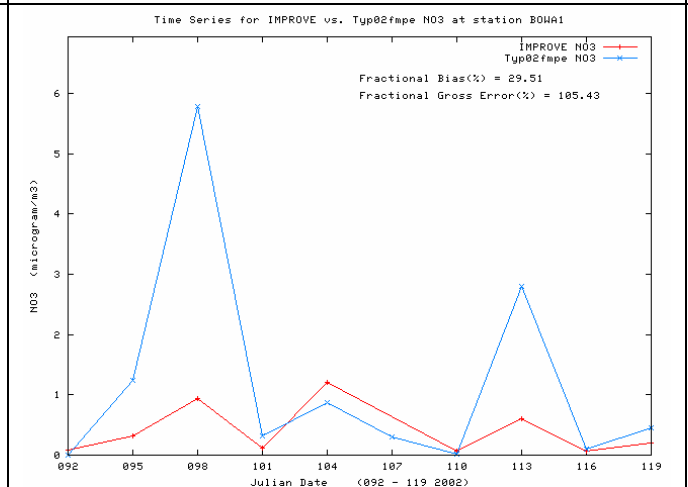

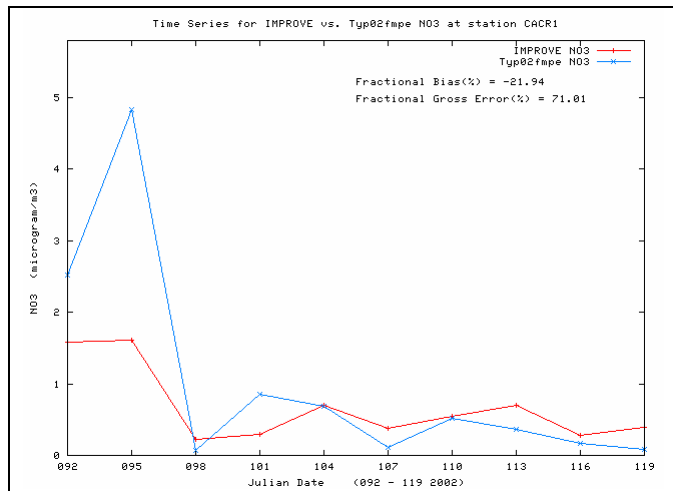

Figure C-11a. Scatter plots of predicted and observed nitrate (NO3) concentrations for April 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

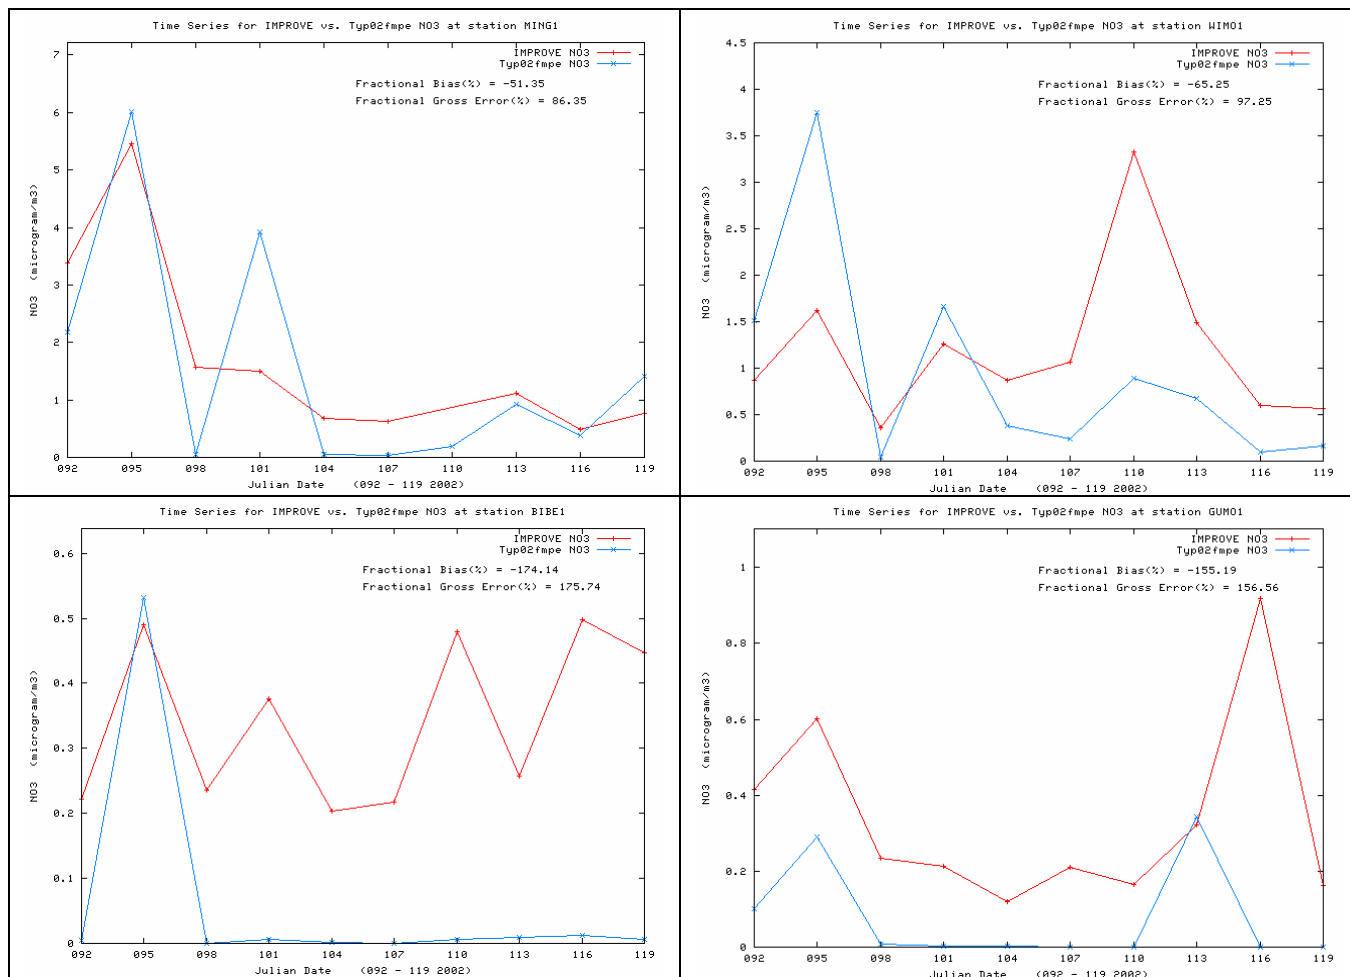

Figure C-11b. Time series of predicted and observed 24-hour nitrate (NO₃) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

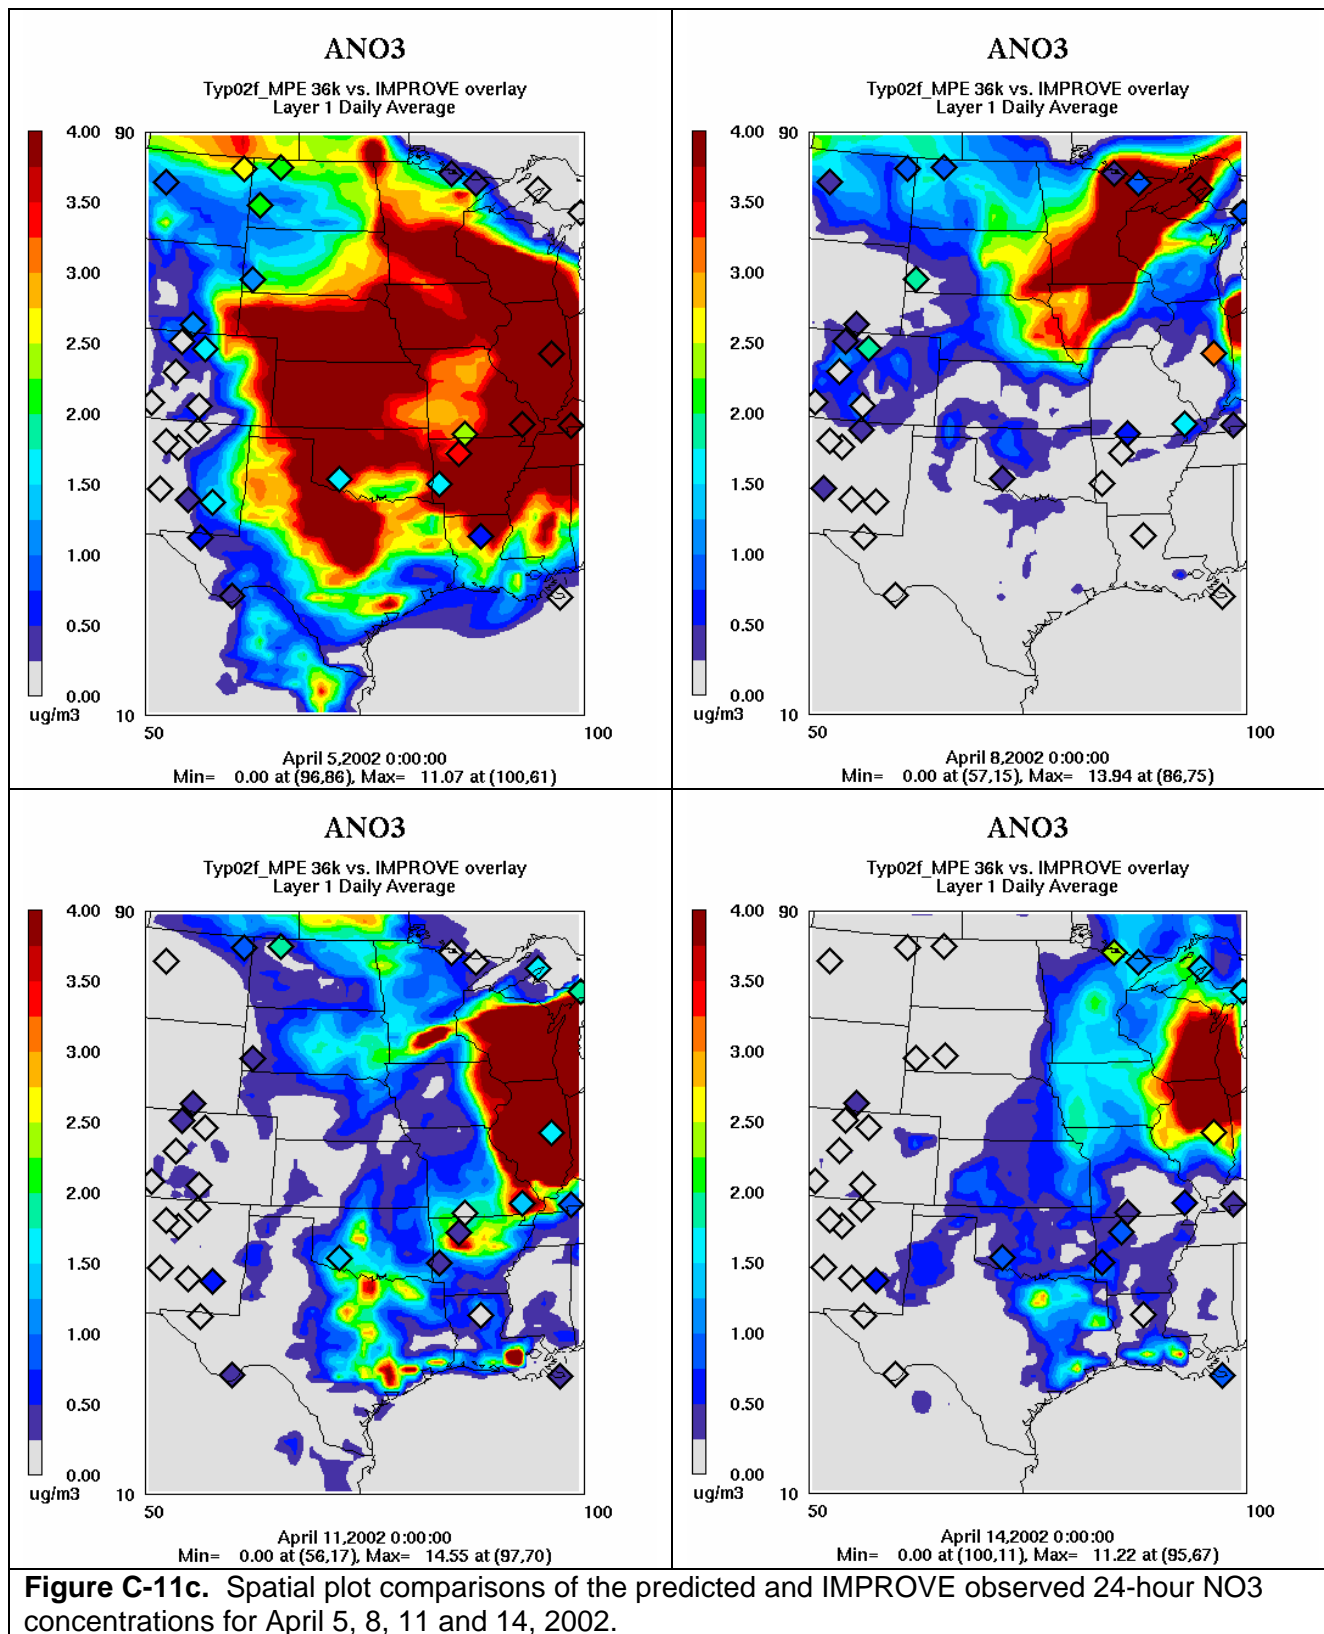

Figure C-11c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour NO₃ concentrations for April 5, 8, 11 and 14, 2002.

C.3.2.3 NO3 in July 2002

NO3 performance in July 2002 is also characterized by a large under-prediction bias that is driven by the frequent occurrence of near zero modeled values (Figure C-12). Both the model and observations agree that NO3 is mostly extremely low in July, just the model produces near zero values and resultant poor performance statistics.

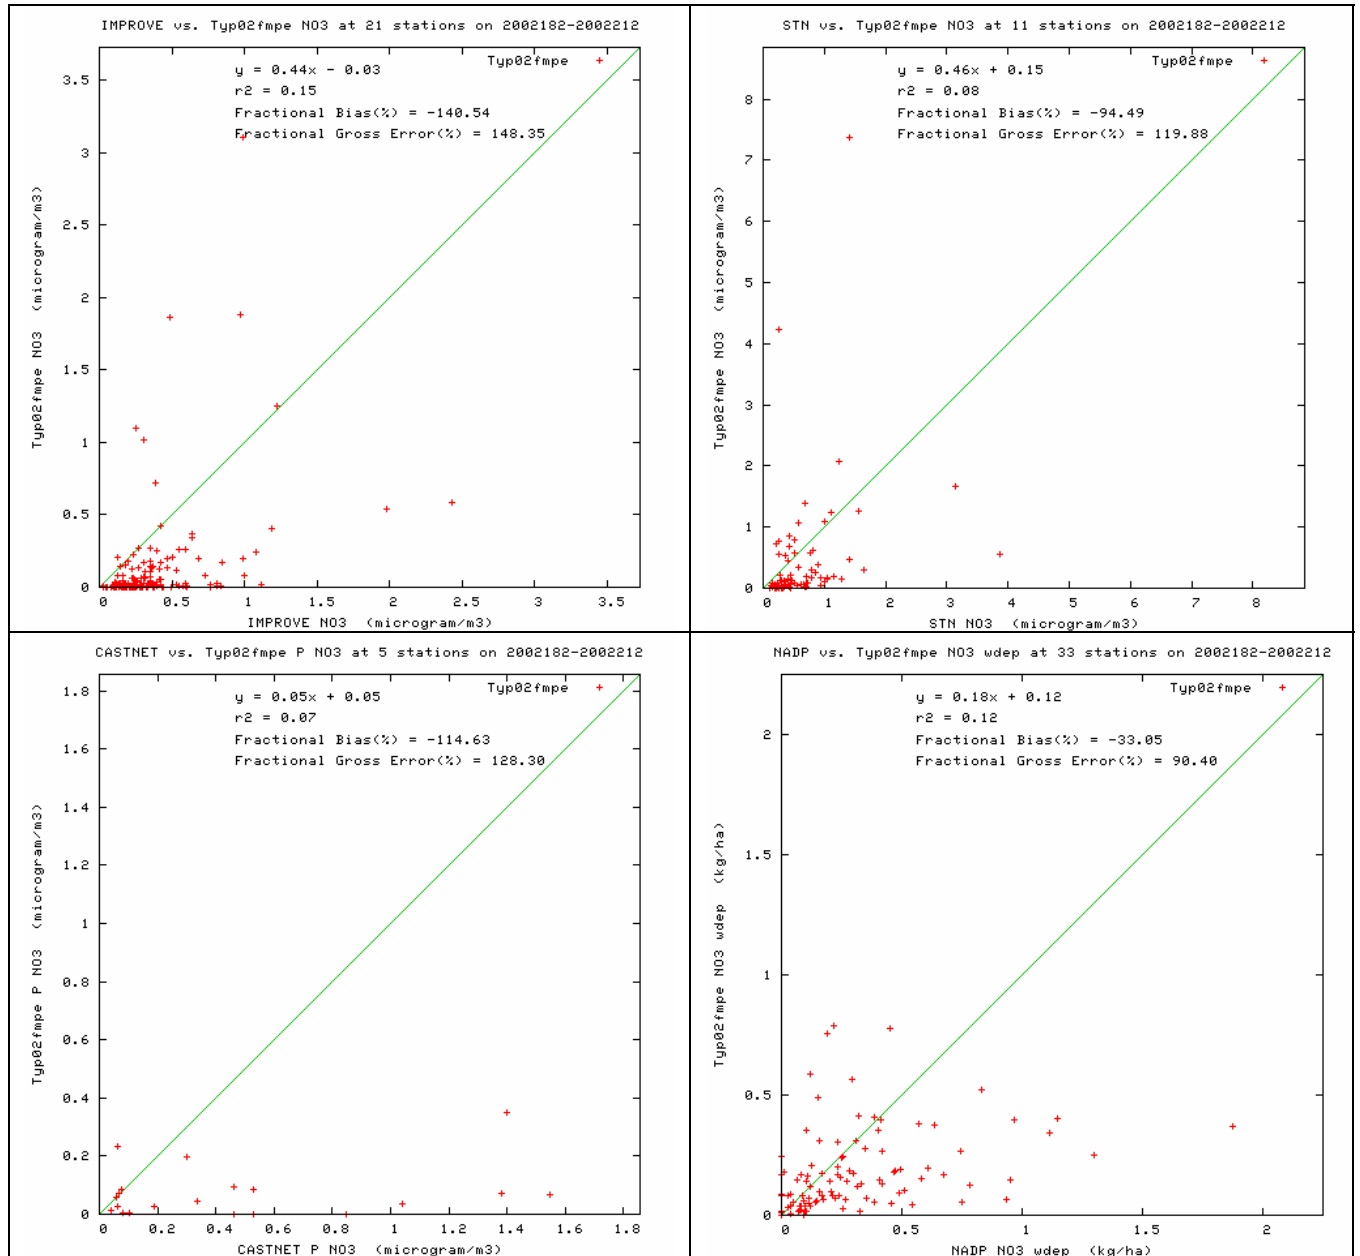

Figure C-12a. Scatter plots of predicted and observed nitrate (NO3) concentrations for July 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-12b. Time series of predicted and observed 24-hour nitrate (NO3) concentrations at CENRAP IMPROVE CLASS I AREA sites in July 2002 for CMAQ 2002 36 km Base F base case simulation.

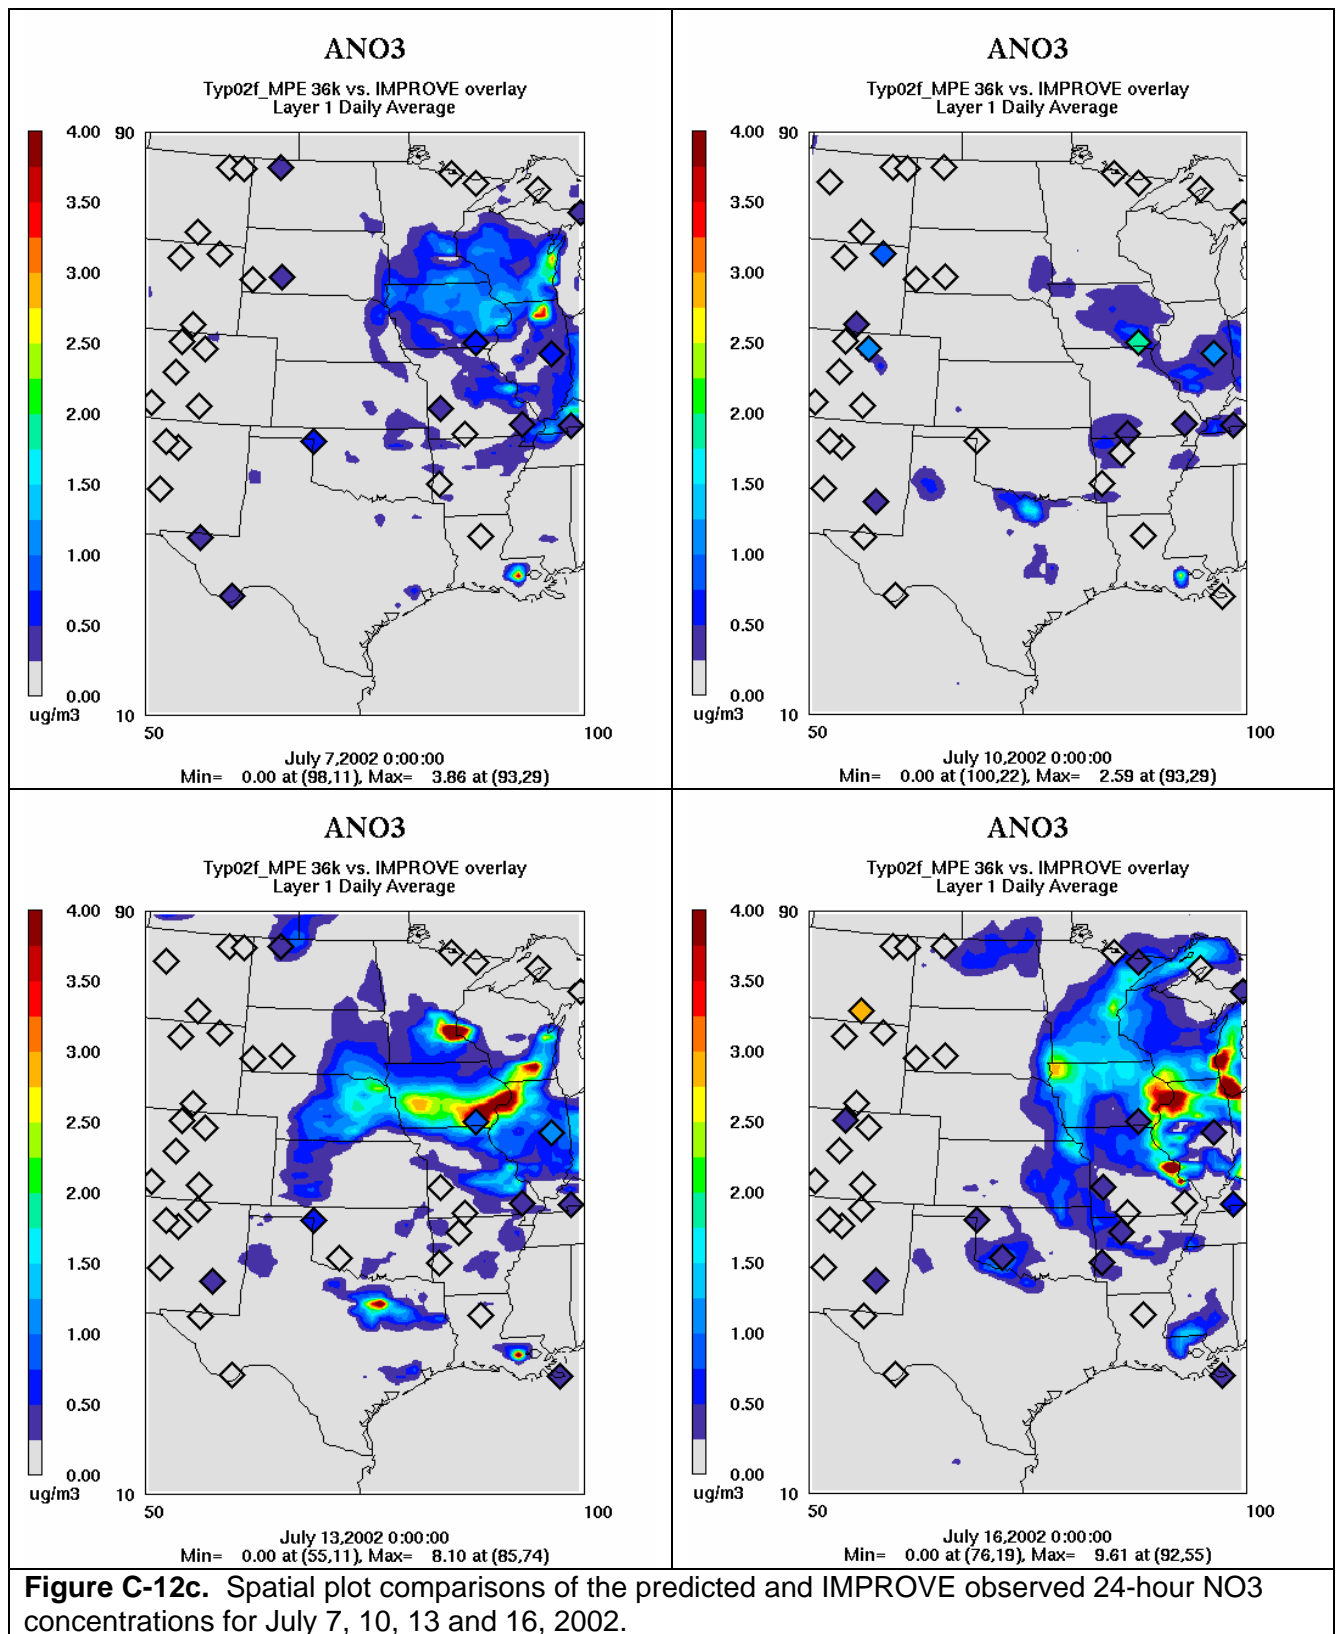

Figure C-12c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour NO3 concentrations for July 7, 10, 13 and 16, 2002.

C.3.2.4 NO3 in October 2002

Like January and unlike April and July, in October the model has a net NO₃ overestimation bias of about 30%-40% (Figure C-13a). This overestimation bias occurs at all sites but BRET, BIBE and GUMO that exhibit a NO₃ underestimation bias (Figure C-13b). The spatial maps suggest that the modeled elevated NO₃ concentrations are more wide-spread and less spotty than observed.

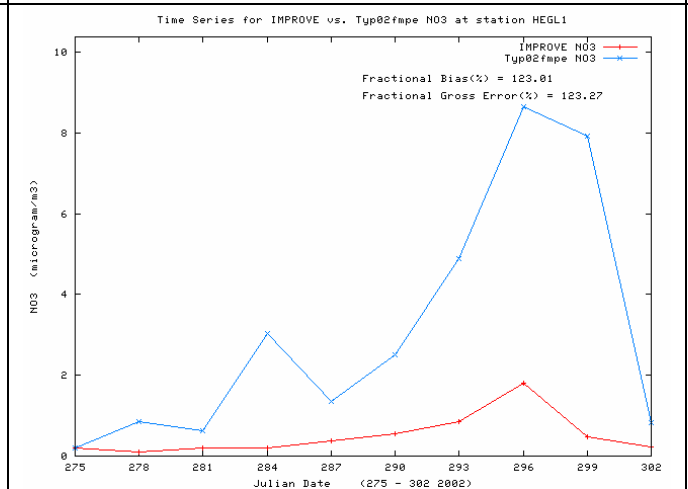

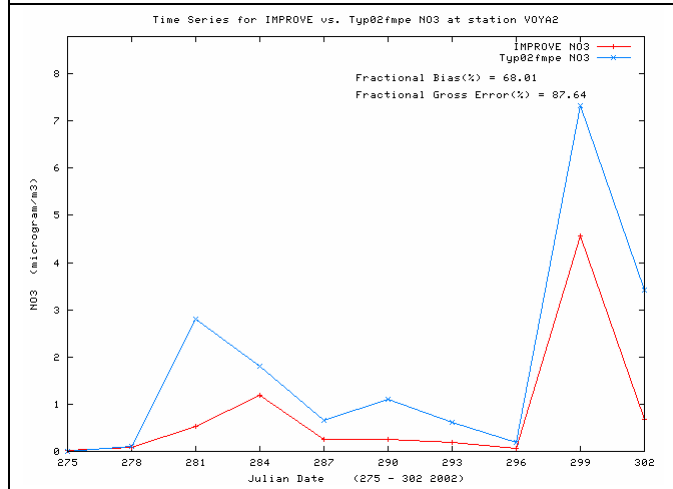

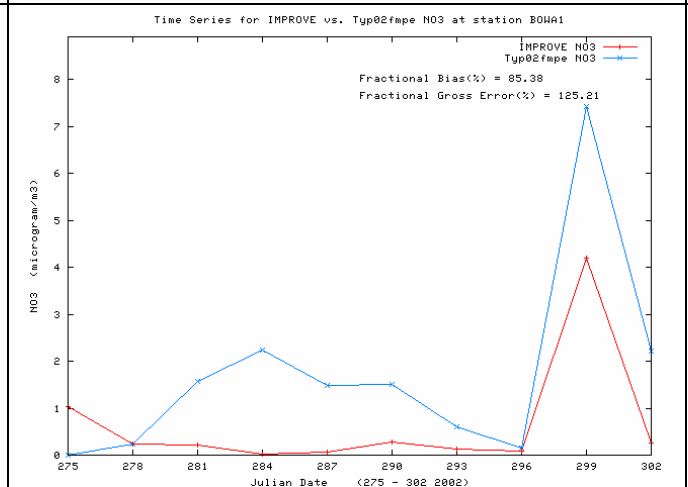

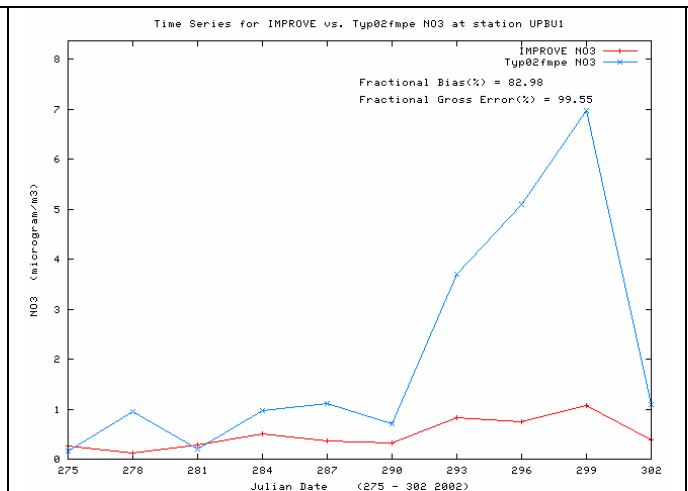

Figure C-13a. Scatter plots of predicted and observed nitrate (NO₃) concentrations for October 2002 and sites in the CENRAP region using IMPROVE (top left), STN (top right), CASTNet (bottom left) and NADP monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-13b. Time series of predicted and observed 24-hour nitrate (NO₃) concentrations at CENRAP IMPROVE CLASS I AREA sites in October 2002 for CMAQ 2002 36 km Base F base case simulation.

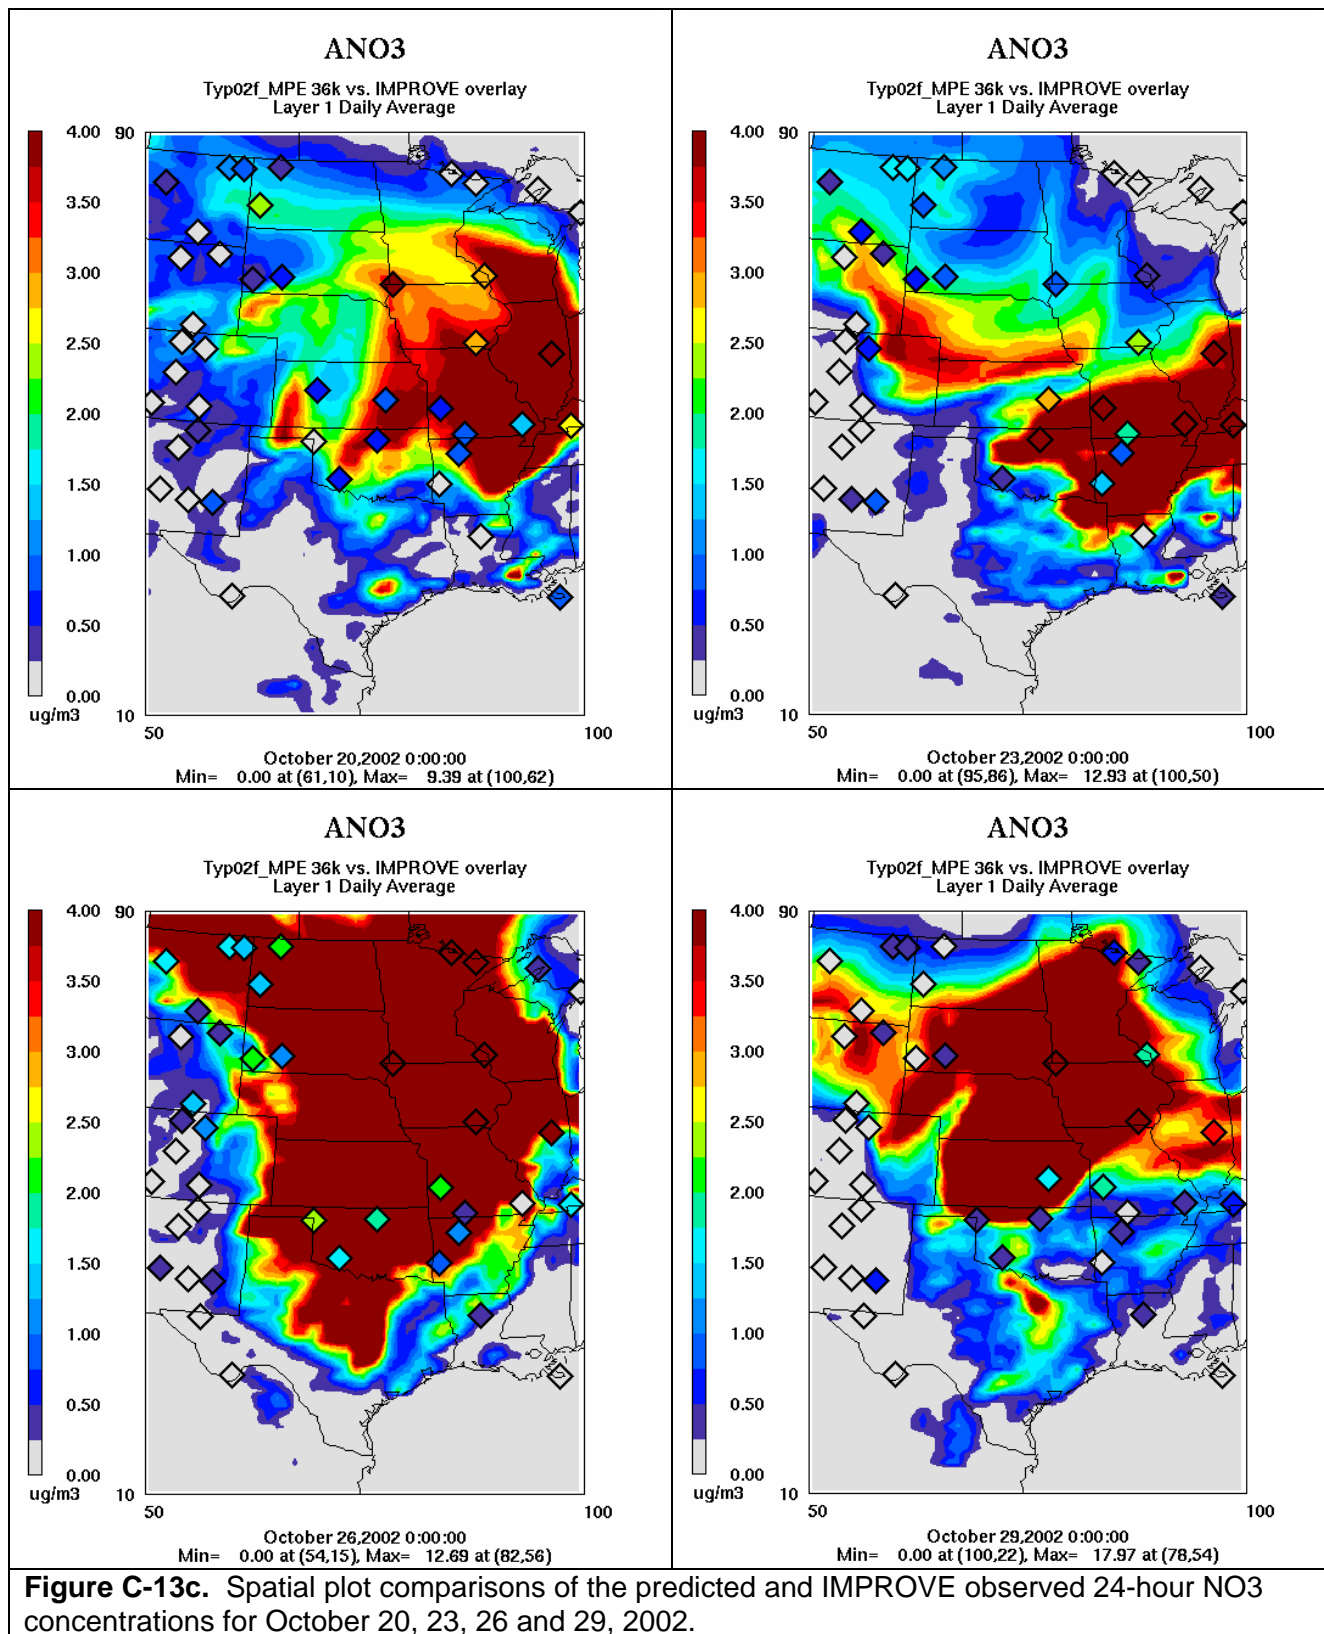

Figure C-13c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour NO3 concentrations for October 20, 23, 26 and 29, 2002.

C.3.2.5 NO₃ Monthly Bias and Error

The monthly fractional bias values for NO₃ clearly show the summer underestimation and winter overestimation bias (Figure C-14). The summer underestimation bias is more severe exceeding -100%, whereas the winter overestimation is closer to 50%. The fractional errors in the summer are also greater than in the winter with some values exceeding 100%. So based on statistics alone, it appears the summer underestimation bias is a bigger concern than the winter overestimation bias. However, the Bugle Plots in Figure C-15 paint a different picture entirely. The summer underestimation bias occurred when NO₃ is low and is not an important component of PM and visibility impairment. These summer values occur in the flared horn part of the Bugle Plot and in fact the summer NO₃ performance mostly achieves the model performance goal and always achieves the performance criteria. Whereas the winter overstated NO₃ performance mostly doesn't meet the performance goal and there are even some months/networks that don't meet the performance criteria.

C.3.3 Organic Matter Carbon (OMC) Monthly Model Performance

Organic Matter Carbon (OMC) model performance is presented below. There is incommensurability between the observed and modeled OMC, the model provides estimates of OMC that includes Organic Carbon (OC) as well as other elements attached to the OC (e.g., oxygen), whereas the monitoring networks measure just the carbon component of OMC (i.e., OC). Consequently, the measured OC must be adjusted to OMC for comparison with the model to account for the additional elements attached to the carbon. The OMC/OC ratio is not constant and depends in part on the age of the OMC with fresh OMC having lower OMC/OC ratios than aged OMC. The original IMPROVE equation used an OMC/OC ratio of 1.4 based mainly on urban-oriented measurements. The new IMPROVE equation uses an OMC/OC ratio of 1.8 reflecting the fact that OMC at the more rural IMPROVE monitors is more aged than urban OMC. Thus, selecting a single OMC/OC ratio for adjusting the measured OC to OMC for the model evaluation is somewhat problematic when we have both urban (STN) and rural (IMPPROVE) monitors. In addition, measured OC also has substantial uncertainty with different measurement techniques differing by as much as 50% (Solomon et al., 2005). A 1.4 OMC/OC ratio was used to convert the measured OC to OMC for the model performance evaluation.

C.3.3.1 OMC in January 2002

Figure C-16a displays scatter plots and performance statistics for January OMC model performance across the IMPROVE and STN sites in the CENRAP region. OMC model performance is fairly with near zero bias across the IMPROVE sites, -38% underestimation bias across the STN sites and errors of ~50%. The underestimation of OMC at the urban STN sites is a common occurrence in air quality modeling and may indicate a missing source of urban OMC. With the exception of an underestimation bias at Breton Island and an over-prediction bias at the two Texas IMPORVE sites (BIBE and GUMO), the model reproduces the observed OMC time series in January fairly well. The modeled spatial distribution of OMC is in general agreement with the observations although it sometimes captures the elevated values on some days (e.g., January 29, 2002 in central Illinois) and misses it on others (e.g., January 26, 2002 at Mingo).

Figure C-16a. Scatter plots of predicted and observed organic matter carbon (OMC) concentrations for January 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

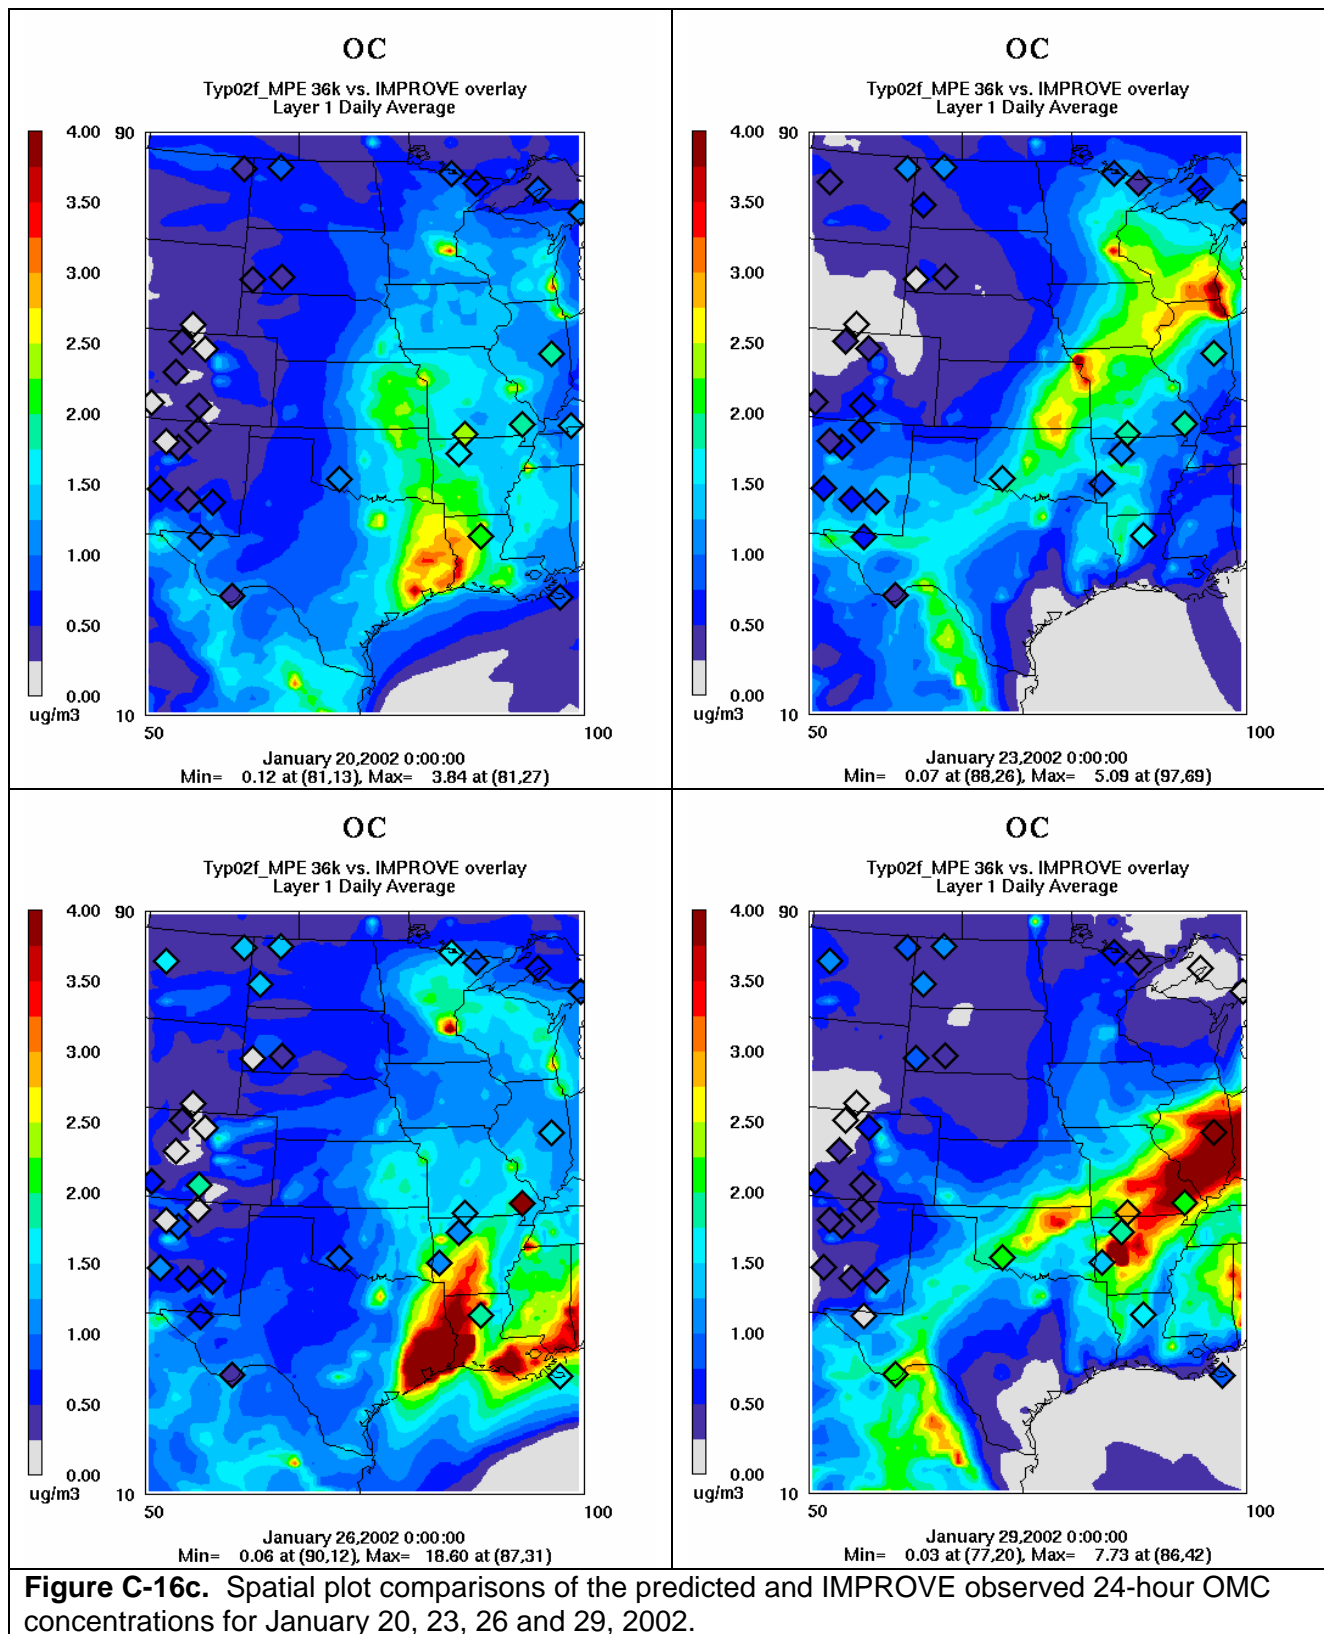

Figure C-16b. Time series of predicted and observed 24-hour organic matter carbon (OMC) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.3.2 OMC in April 2002

The OMC performance in April is also fairly reasonable, again bias across the IMPROVE monitors is near zero (-7%), an underestimation bias exists across the STN sites (-30%) and errors are near 50% (Figure C-17a). The time series comparisons (Figure C-17b) are also reasonable with the model generally agreeing on the magnitudes of the observed OMC, but with an underestimation bias at several sites (e.g., MING and WIMO). The observed spatial distribution of OMCV appears to be much spottier than predicted (Figure C-17c). Thus, when the model reproduces an elevated observed OMC value like at UPBU on April 5th, it overestimates OMC at neighboring sites that have lower values (e.g., HEGL).

Figure C-17b. Time series of predicted and observed 24-hour organic matter carbon (OMC) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

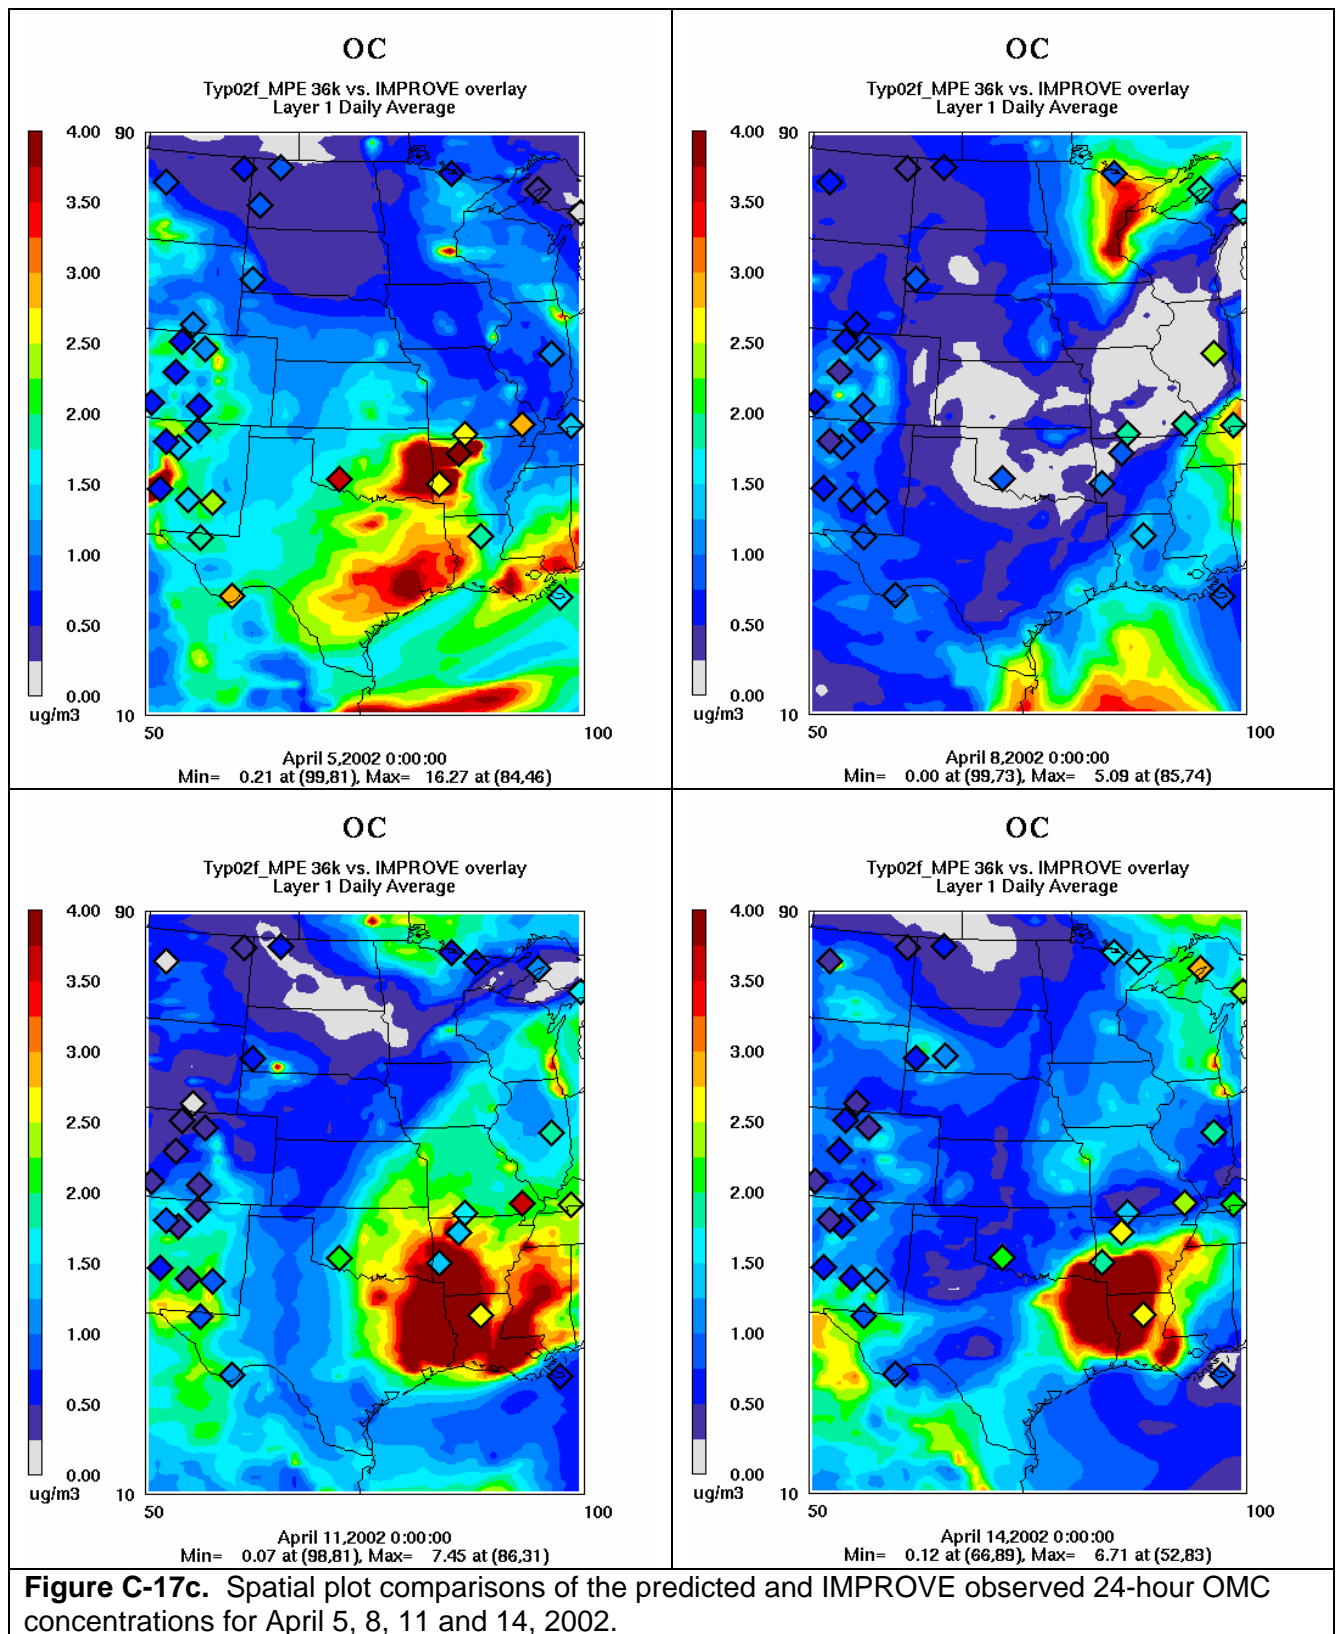

Figure C-17c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour OMC concentrations for April 5, 8, 11 and 14, 2002.

C.3.3.3 OMC in July 2002

Modeled and observed OMC are higher in July due to the impacts of more secondary organic aerosols (SOA) and fires. OMC bias values of -18% and -41% exist across the IMPROVE and STN networks in July (Figure C-18a). Two of the observed OMC values at the IMPROVE sites are very high ($> 15 \mu\text{g}/\text{m}^3$). An examination of the time series plots (Figure C-18b) reveals that these two values occur on Julian Day 200 and the two northern Minnesota sites (VOYA and BOWA) and are likely due to fire impacts. The model is also estimating elevated OMC at these sites on these two days, but not as high as observed. At most sites the model is tracking the temporal variation of the observed OMC reasonably well. OMC data for MING were missing in July 2002. The model reproduces the observed high OMC in northern Minnesota and centered on Louisiana and adjacent areas on July 7 and 10 quite well, but also predicts elevated OMC in the Denver area that is not reflected in the observations (Figure C-18c). The model is exhibiting less skill in predicting the spatial distribution of the observed OMC on July 13 and 16.

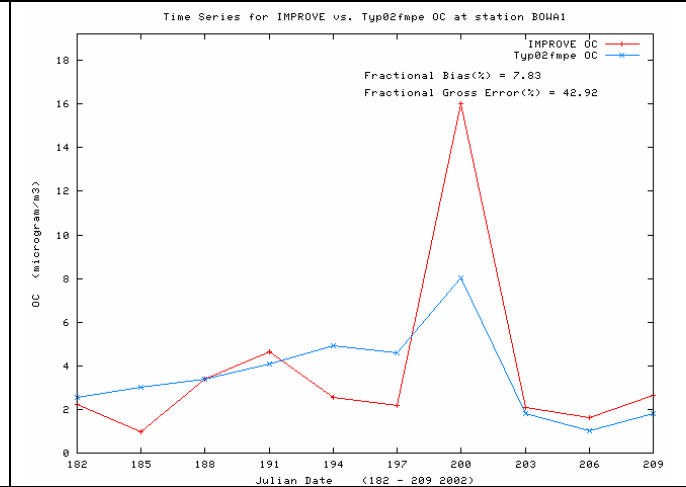

Figure C-18a. Scatter plots of predicted and observed organic matter carbon (OMC) concentrations for July 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

No Data for Mingo (MING)

Figure C-18c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour OMC concentrations for July 7, 10, 13 and 16, 2002.

C.3.3.4 OMC in October 2002

OMC model performance in October 2002 is similar to the other months with near zero bias across the IMPROVE sites and an underestimation bias across the STN sites in the CENRAP region (Figure C-19a). Although OMC overestimation bias occurs at the Texas sites (BIBE and GUMO), the model is exhibiting remarkable ability to reproduce the observed temporal variation in OMC at several of the sites (e.g., CACR, UPBU, VOYA and HEGL; Figure C-19b). The model also performs reasonable well in reproducing the day to day and spatial variability in the observed OMC (Figure C-19c).

No Data for Mingo (MING)

Figure C-19c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour OMC concentrations for October 20, 23, 26 and 29, 2002.

C.3.3.5 OMC Monthly Bias and Error

The OMC monthly bias and error across IMPROVE and STN sites in the CENRAP region are shown in Figure C-20. The bias performance for OMC at the IMPROVE sites are quite good throughout the year with values generally within $\pm 20\%$, albeit with a slight winter overestimation and summer underestimation bias. At the urban STN sites the model exhibits an underestimation bias throughout the year that ranges from -20% to -50%. Fractional errors are mostly within 40% to 60% with the STN network generally exhibiting more error than IMPROVE.

The good performance of the model for OMC at the IMPROVE sites is also reflected in the Bugle Plot (Figure C-21) with the bias and error achieving the proposed PM model performance goal for all months of the year. At the STN sites, however, the OMC bias falls between the proposed PM model performance goal and criteria, with error right at the goal for most months.

Figure C-20. Monthly OMC fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE and STN monitoring sites in the CENRAP region.

OC

Figure C-21. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for OMC and IMPROVE and STN monitoring sites in the CENRAP region.

C.3.4 Elemental Carbon (EC) Monthly Model Performance

Elemental Carbon (EC) measurements are also uncertain, with the IMPROVE and STN using different measurement technologies with different measurement artifacts.

C.3.4.1 EC in January 2002

Although there is a lot of scatter in the January EC scatter plots at the IMPROVE and STN sites, the bias is fairly low (-24% and 1%) with errors in the 40%-50% range (Figure C-22a). The time series comparisons (Figure C-22b) suggest an EC underestimation bias at BRET and an overestimation bias at the northern Minnesota sites (VOYA and BOWA). The model generally agrees with the observed spatial distribution of EC in January with higher values on the eastern than western portions of the CENRAP region (Figure C-22c).

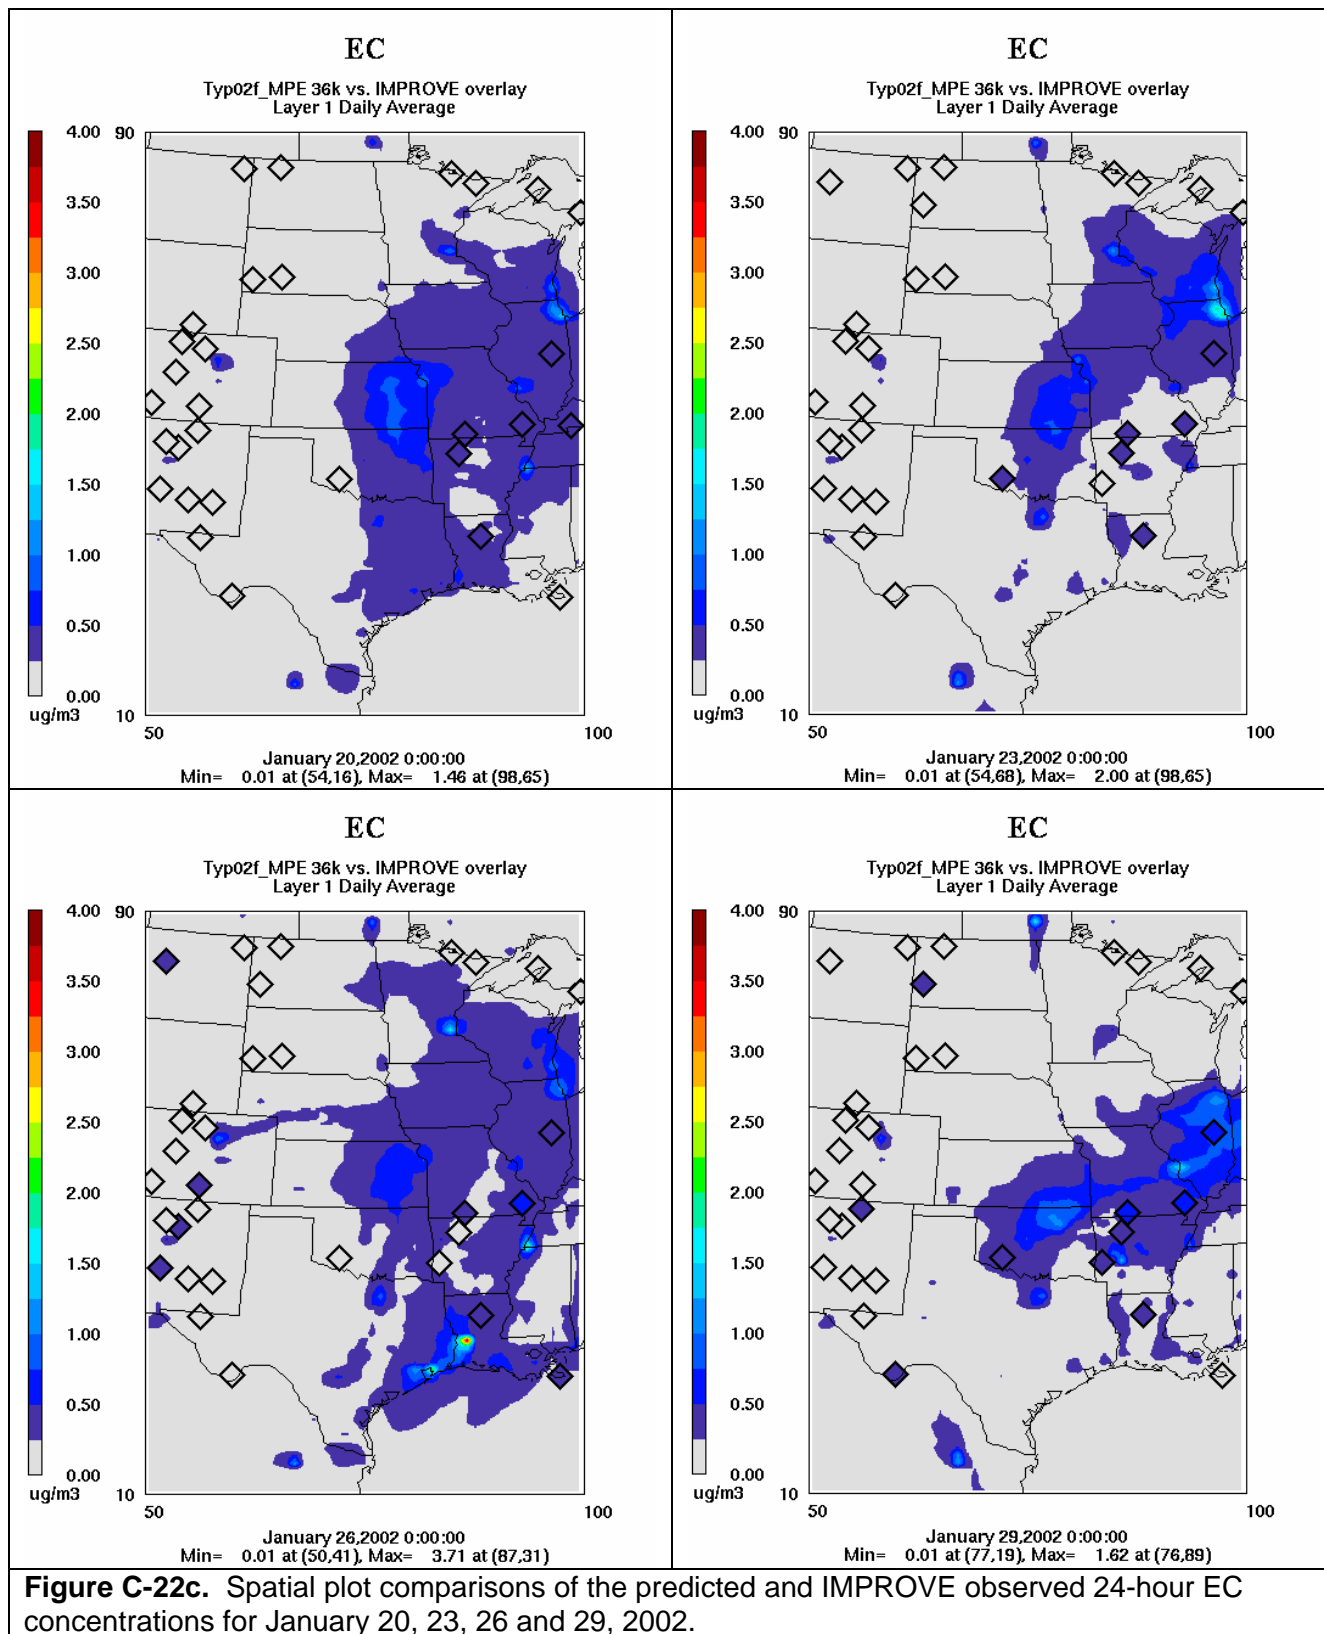

Figure C-22b. Time series of predicted and observed 24-hour elemental carbon (EC) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.4.2 EC in April 2002

EC is underestimated at the IMPROVE sites in April (bias of -48%), but reproduced well at the STN sites (bias of -13%). Although EC is underestimated at the IMPROVE sites both the model and observations agree that EC concentrations are very small and not a significant component of the PM budget. The model fails to capture the day-to-day variability in the observed EC at the IMPROVE sites and exhibits a systematic under-prediction tendency at some sites (Figure C-23b). On April 5 and 11 the model reproduces the spatial distribution of the observed EC reasonable well with higher values in the eastern than western portion of the CENRAP region. But on April 8 and 14 the model is much to clean in the eastern portion of the CENRAP region (Figure C-23c).

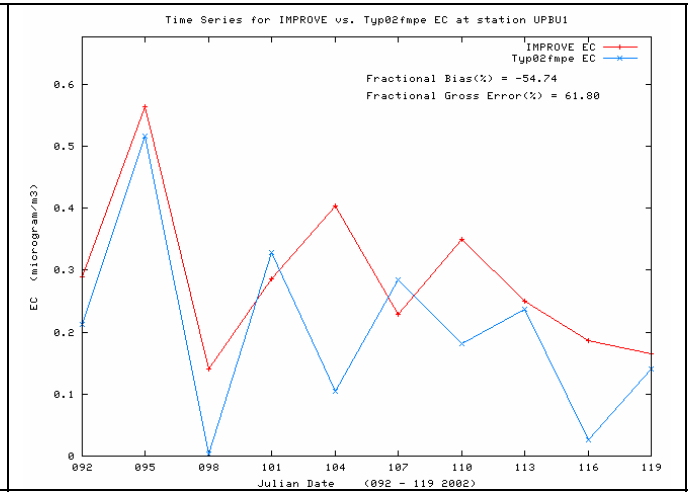

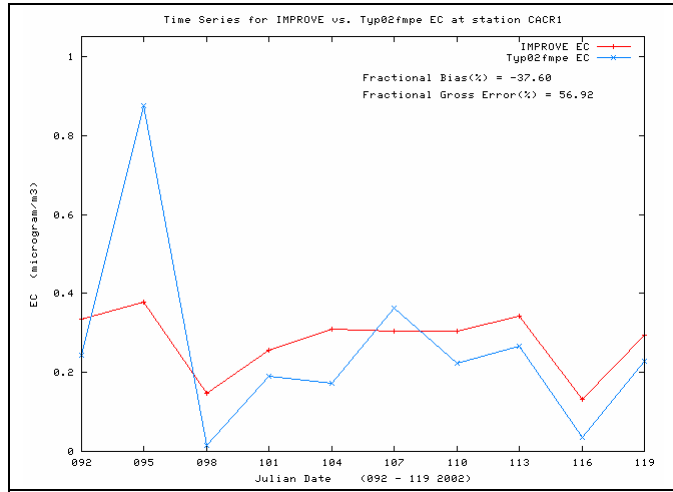

Figure C-23a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for April 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation

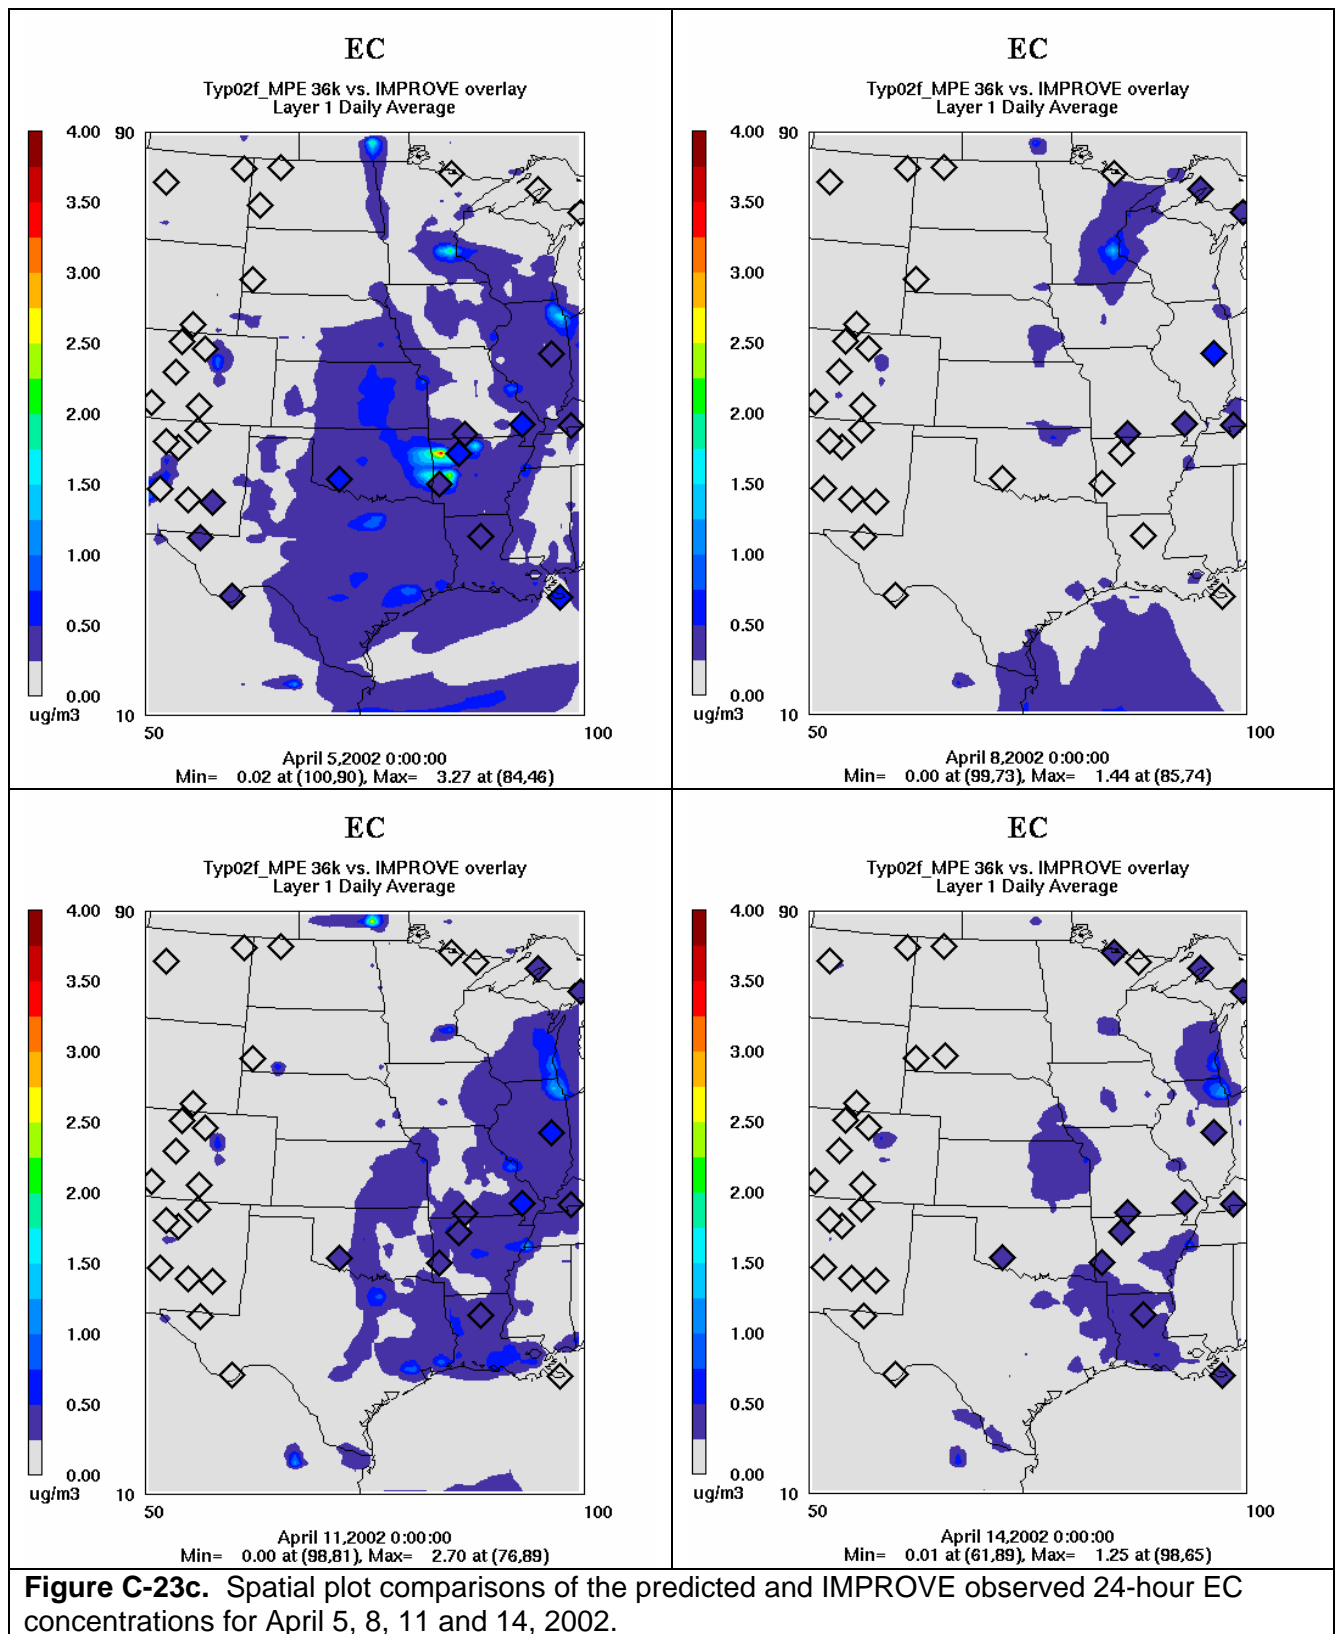

Figure C-23b. Time series of predicted and observed 24-hour elemental carbon (EC) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.3.3 EC in July 2002

July EC performance is similar to the other months with near zero bias across the STN sites and an underestimation bias across the IMPROVE sites (Figure C-24). Again the model and observations agree that EC is low in July and not a significant component of visibility impairment.

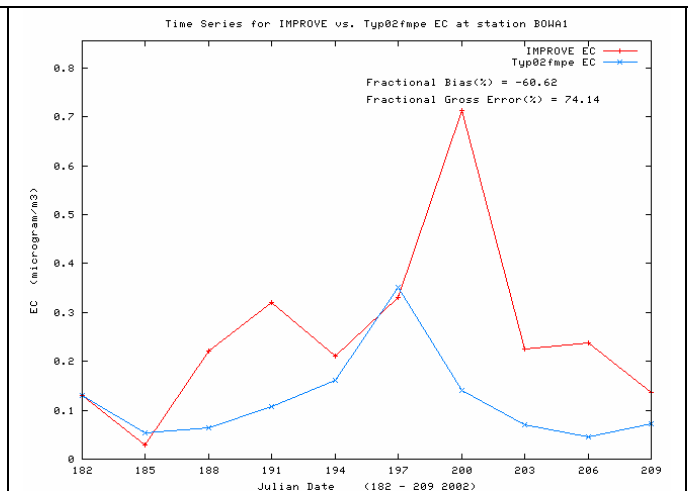

Figure C-24a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for July 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

No Data for Mingo (MING)

Figure C-24b. Time series of predicted and observed 24-hour elemental carbon (EC) concentrations at CENRAP IMPROVE CLASS I AREA sites in July 2002 for CMAQ 2002 36 km Base F base case simulation.

Figure C-24c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour EC concentrations for July 7, 10, 13 and 16, 2002.

C.3.4.4 EC in October 2002

EC performance is improved at the IMPROVE sites in October with lower bias (9%) than the previous months where an under-prediction tendency was seen (Figure C-25a). EC bias is also fairly low at the STN sites with errors across both networks of approximately 50%. Although there is a systematic underestimation of EC at BRET, the agreement between the predicted and observed October time series (Figure C-25b) is remarkable at several sites (e.g., CACR, UPBU, VOYA and HEGL).

Figure C-25a. Scatter plots of predicted and observed elemental carbon (EC) concentrations for October 2002 and sites in the CENRAP region using IMPROVE (left) and STN (right) monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

No Data for Mingo (MING)

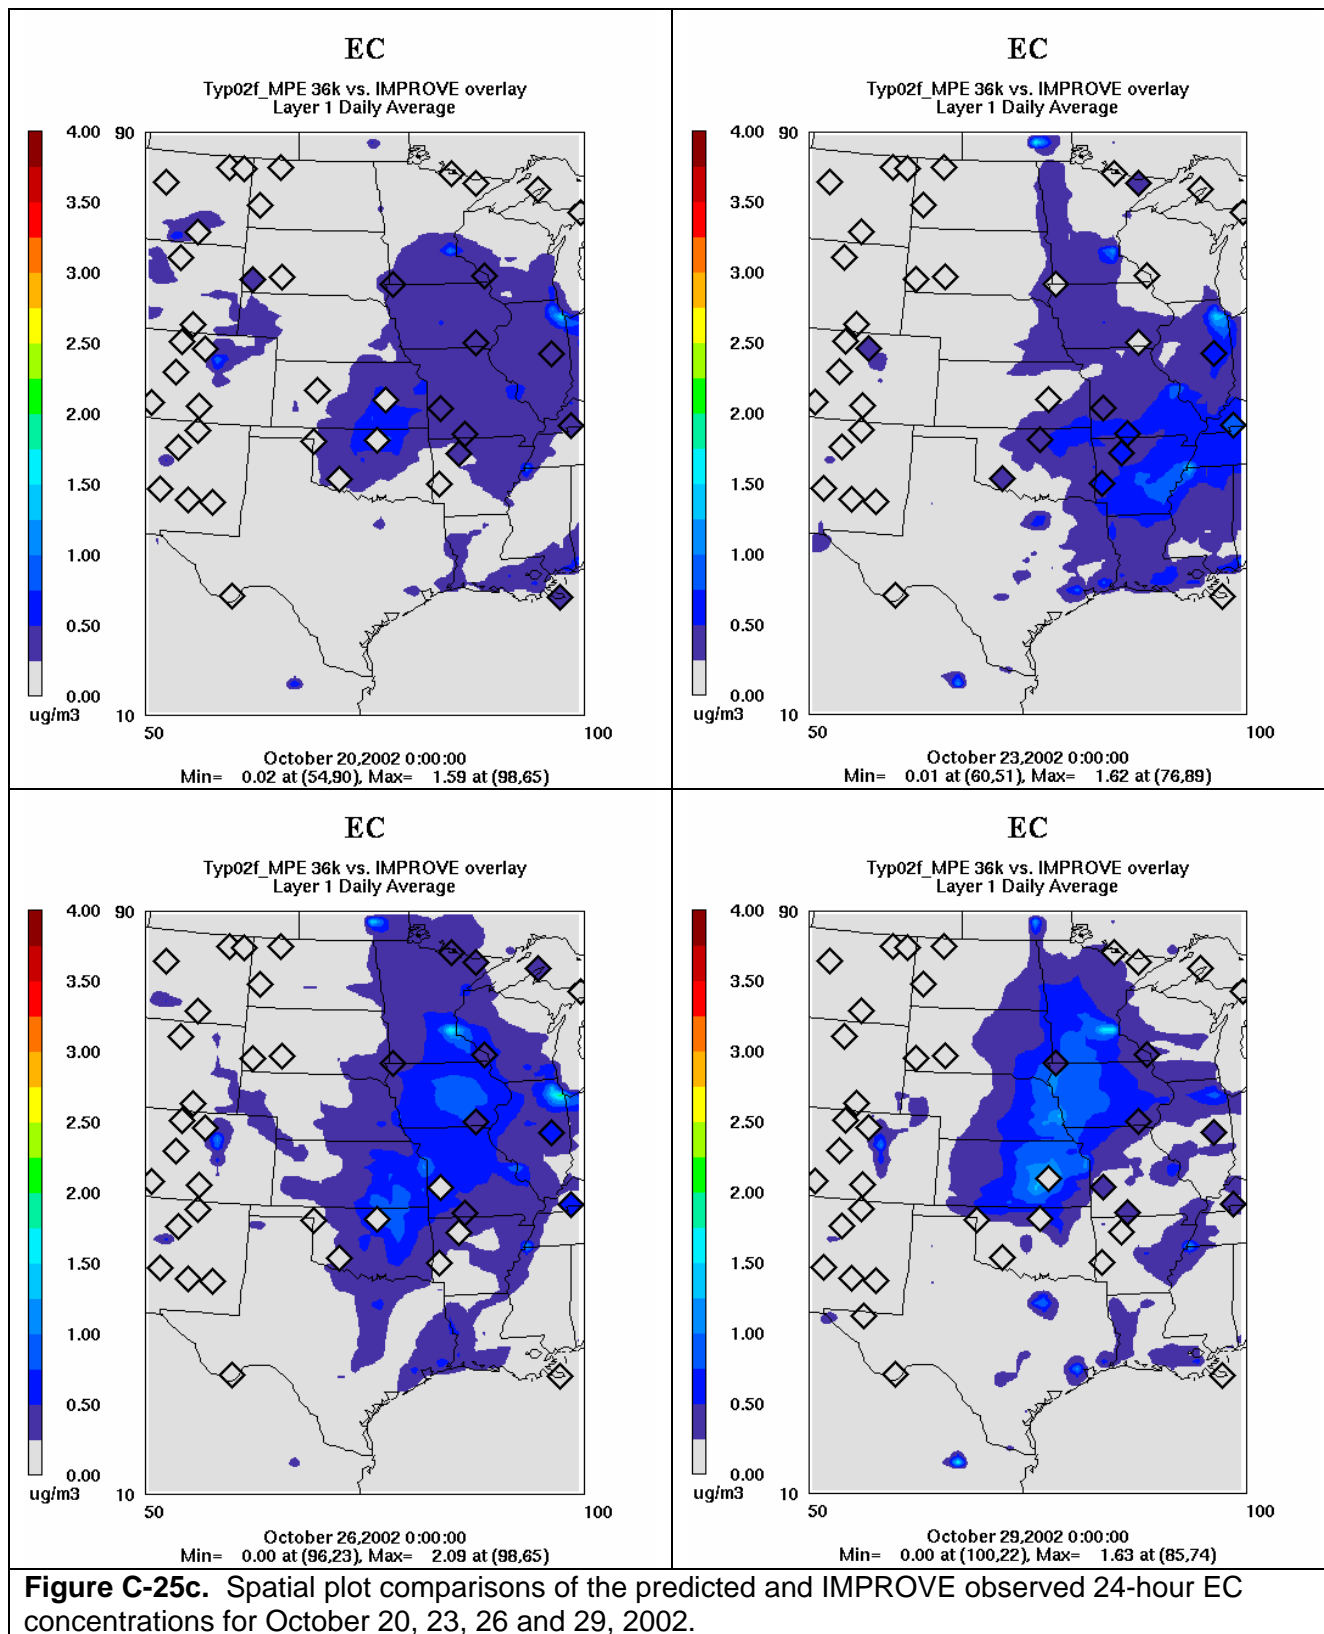

Figure C-25b. Time series of predicted and observed 24-hour elemental carbon (EC) concentrations at CENRAP IMPROVE CLASS I AREA sites in October 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.4.5 EC Monthly Bias and Error

The monthly average bias and error for EC across the IMPROVE and STN monitors in the CENRAP region are shown in Figure C-26. The STN network exhibits low bias year round, whereas the IMPROVE monitoring network exhibits a large under-prediction bias in the summer months (-40% to -60%) and much lower EC bias in the winter. The errors in the IMPROVE summer EC performance are also quite high (60% to 80%), whereas during the winter the IMPROVE errors are in the 40% to 50% range which is also where the STN errors reside year round.

The Bugle Plot puts the EC performance in context (Figure C-27). The low EC concentrations put the IMPROVE EC performance in the horn of the Bugle Plot so that it achieves the proposed PM performance goal for all months of the year.

EC

Figure C-27. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for EC and IMPROVE and STN monitoring sites in the CENRAP region.

C.3.5 Other PM_{2.5} (Soil) Monthly Model Performance

There are also model-measurement incommensurability problems with the other PM_{2.5} (Soil) species. Whereas the IMPROVE Soil species is built up from measure elements, the modeled other PM_{2.5} concentrations are based on emissions speciation profiles that likely include other species besides just elements. Soil is only collected at the IMPROVE monitors.

C.3.5.1 Soil in January 2002

The model greatly overestimates the Soil species at IMPORVE sites in January (Figure C-28a). The fractional bias exceeds 100% with errors of almost 130%. With the possible exception of the two Texas sites, the model Soil overestimation bias occurs across all of the CENRAP Class I areas in January (Figure C-28b). The model also does a poor job in reproducing the spatial variability of the observed Soil with a general overestimation tendency except at GUMO where it fails to reproduce the high Soil events.

Figure C-28a. Scatter plots of predicted and observed other PM_{2.5} (Soil) concentrations for January 2002 and sites in the CENRAP region using IMPROVE monitoring network and the CMAQ 2002 36 km Base F base case simulation.

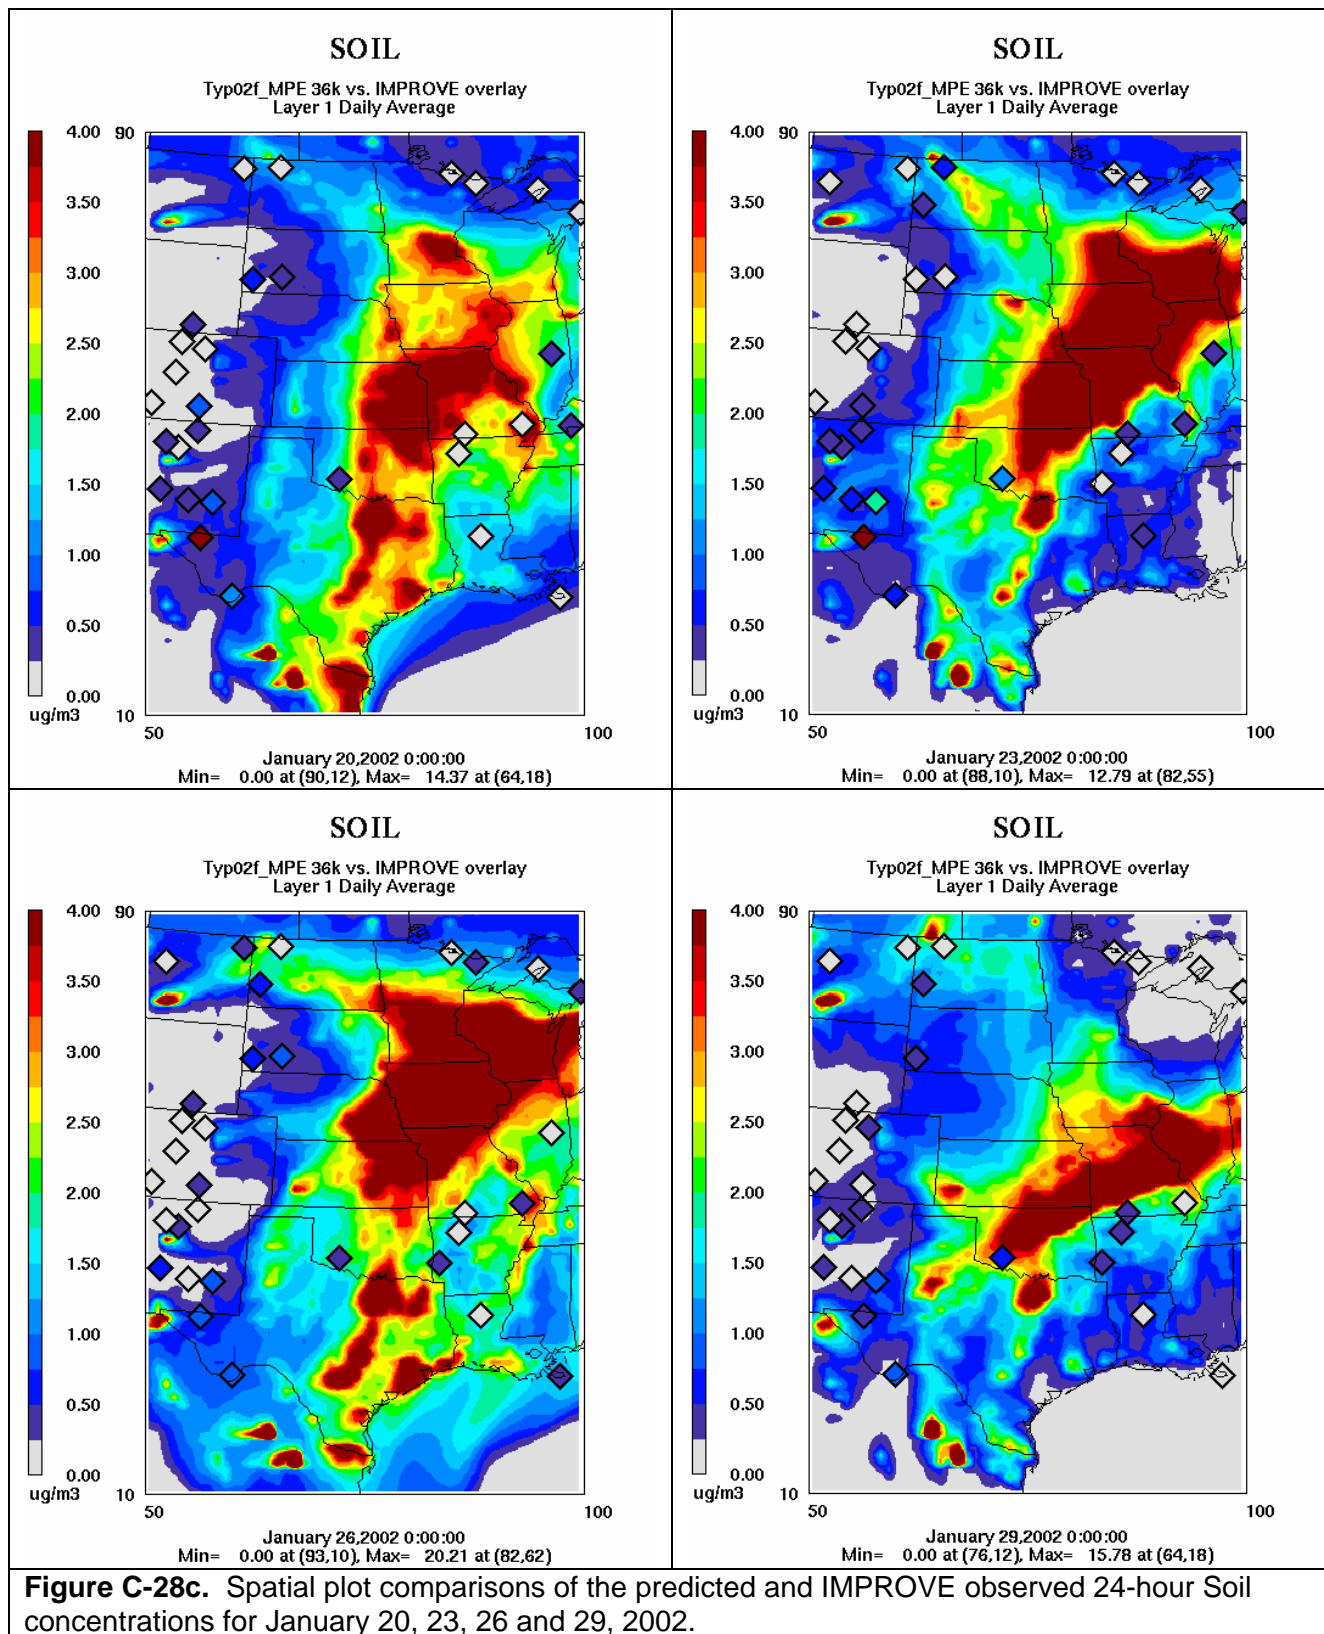

Figure C-28b. Time series of predicted and observed 24-hour other PM_{2.5} (Soil) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.5.2 Soil in April 2002

The model does a better job in reproducing the overall magnitude of the Soil measurements in April with a bias of 13% (Figure C-29a). But it exhibits little skill with lots of scatter and an error of 81%.

The model is generally exhibiting a lot more day-to-day variability than observed with the observed daily time series much flatter than the modeled values (Figure C-29b). The modeled and observed spatial variability in Soil on April 5, 8, 11 and 14 are shown in Figure C-29c. Although the model exhibits large day-to-day variability, the observations do not reflect what the model predicts.

Figure C-29a. Scatter plots of predicted and observed other PM_{2.5} (Soil) concentrations for April 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

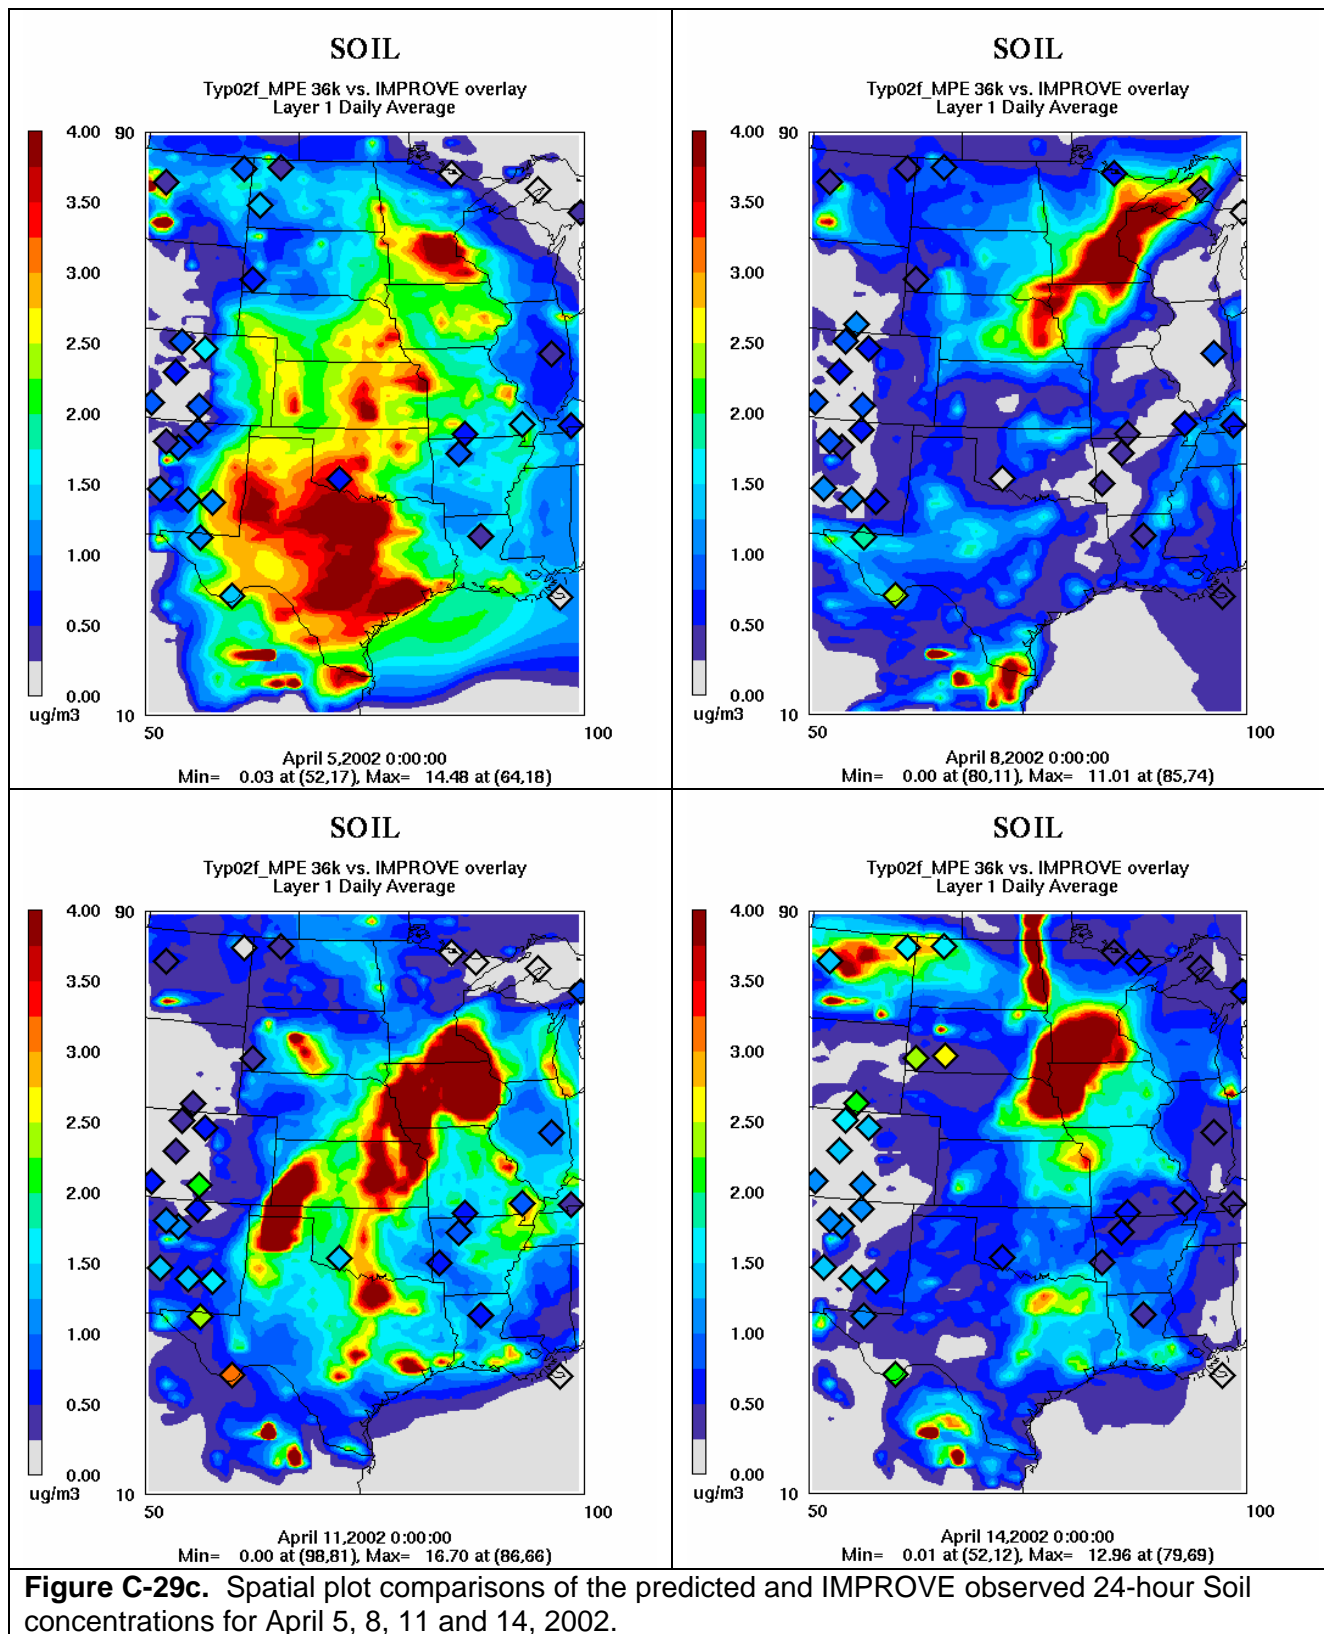

Figure C-29b. Time series of predicted and observed 24-hour other PM_{2.5} (Soil) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.5.3 Soil in July 2002

The -50% Soil under-prediction bias seen in July appears to be driven to several high Soil measurements (Figure C-30a). An observed high Soil event took place on July 1 (Julian Day 182) across the Arkansas and Missouri Class I areas that all observed Soil values in excess of $15 \mu\text{g}/\text{m}^3$. This event was not captured by the model. With the exception of a systematic Soil underestimation bias at the two Texas sites and missing these high Soil events, the model generally reproduces the magnitudes of the Soil observations in July.

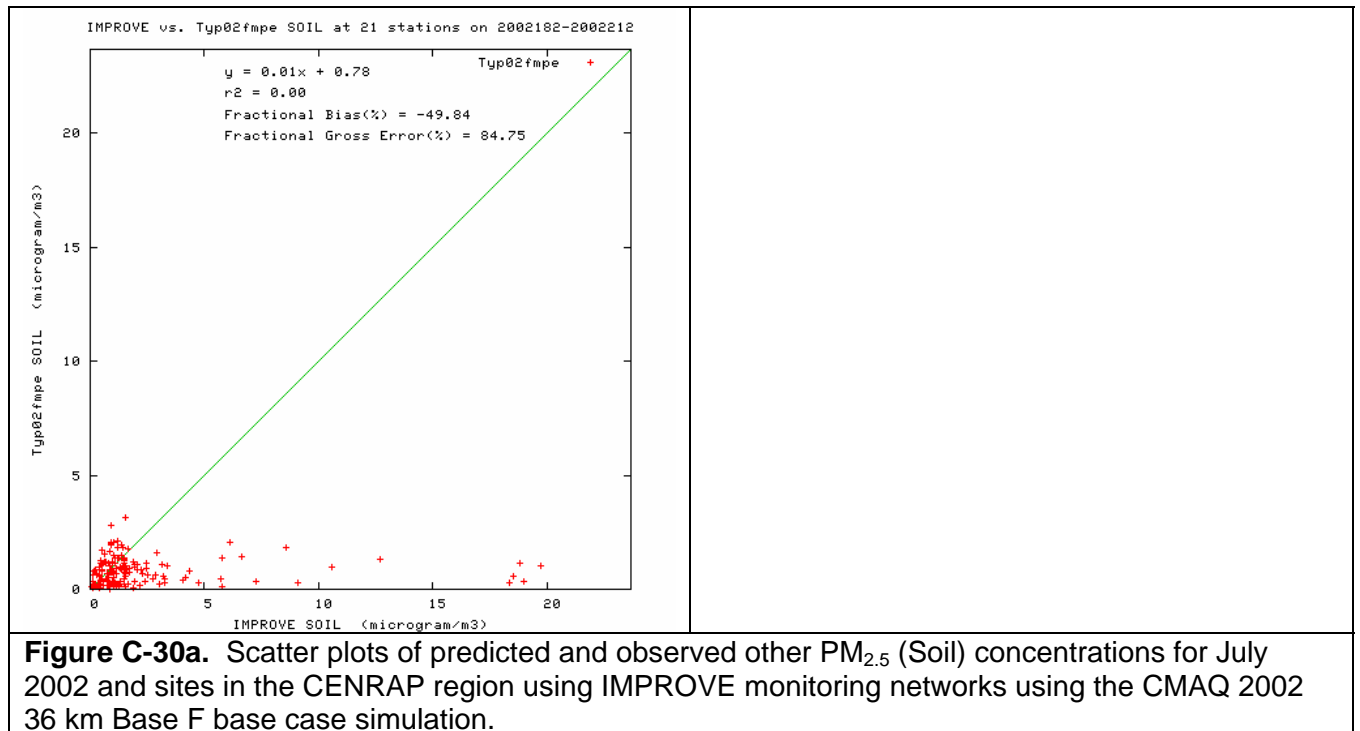

Figure C-30a. Scatter plots of predicted and observed other $\text{PM}_{2.5}$ (Soil) concentrations for July 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-30b. Time series of predicted and observed 24-hour other PM_{2.5} (Soil) concentrations at CENRAP IMPROVE sites in July 2002 for CMAQ 2002 36 km Base F base case simulation.

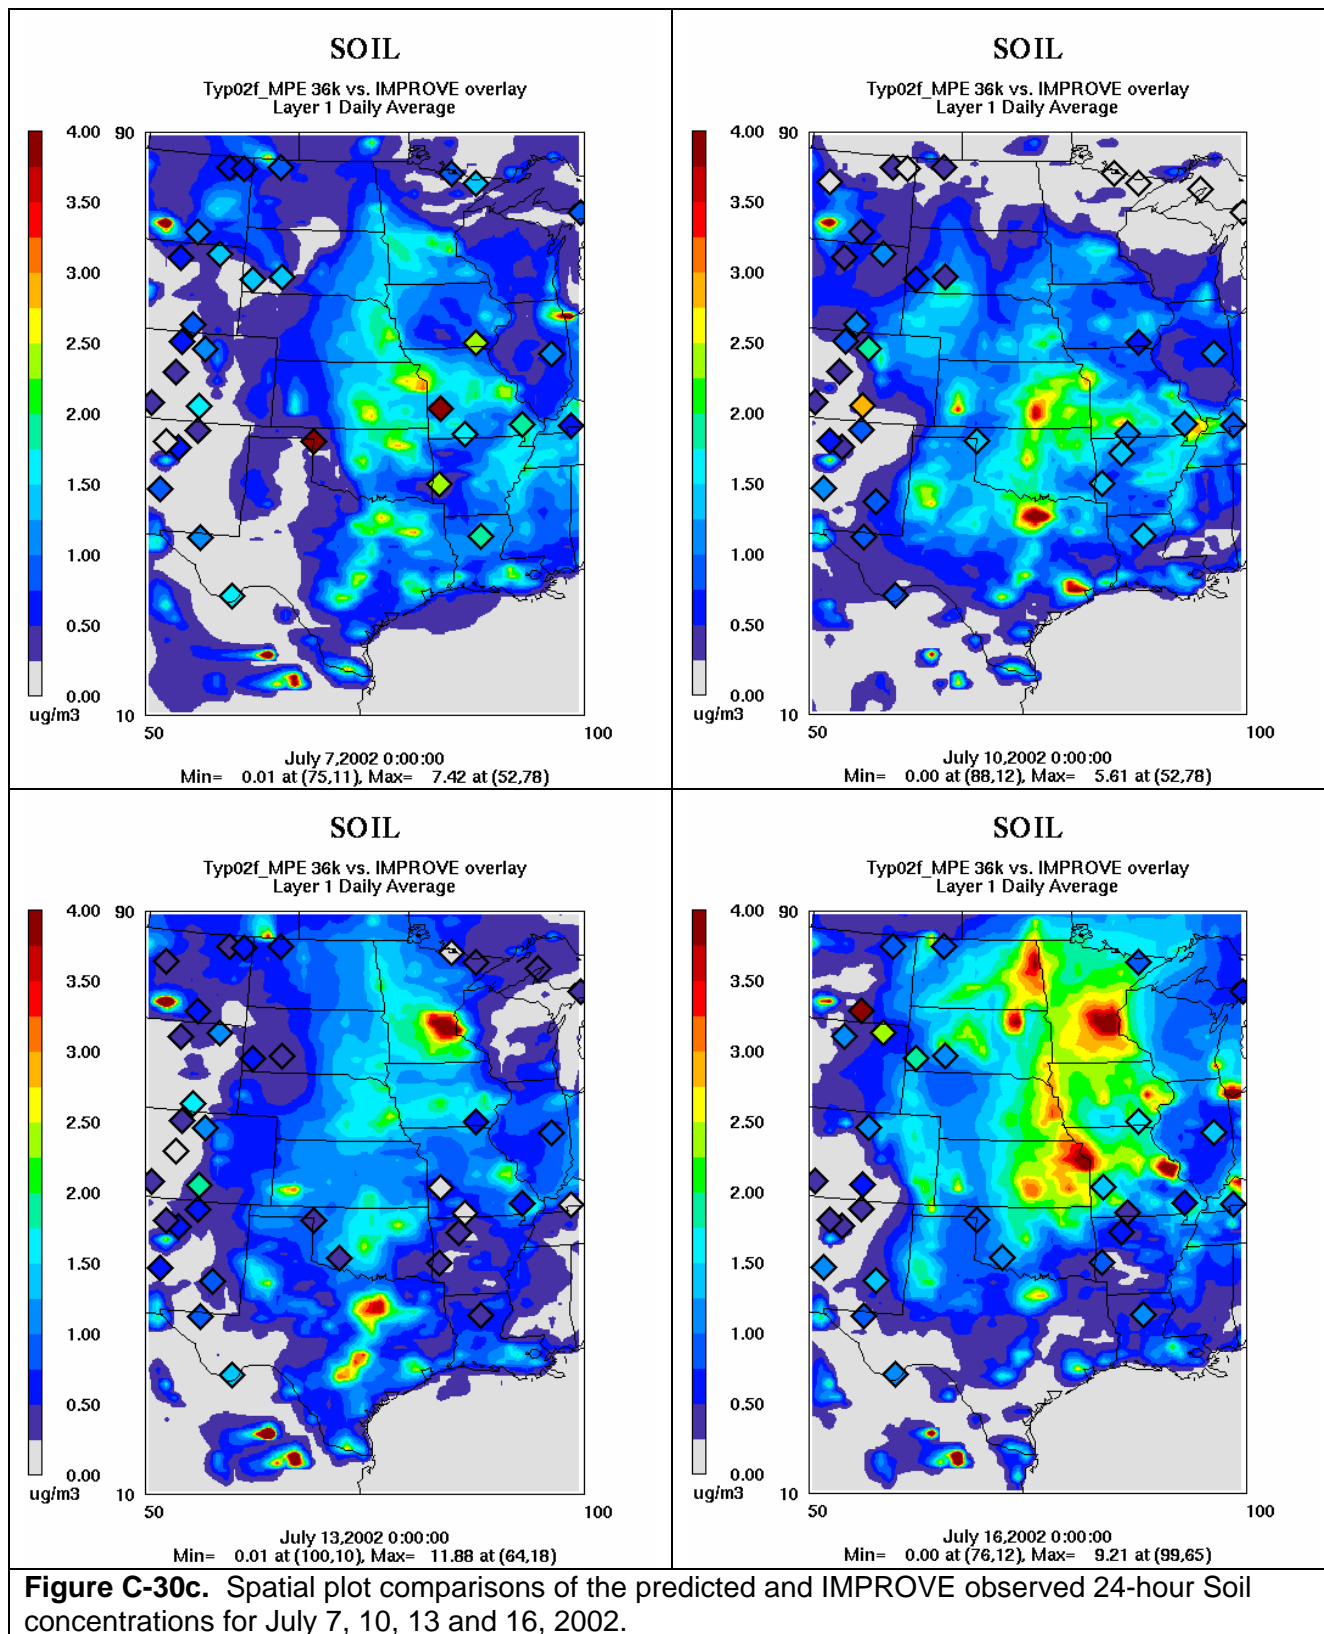

Figure C-30c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour Soil concentrations for July 7, 10, 13 and 16, 2002.

C.3.5.4 Soil in October 2002

The nearly systematic Soil over-prediction bias seen in January returns in October (Figure C-31a). Except for the two Texas sites, BRET and BOWA, the model overstates the observed Soil during all days of October at the other monitoring sites (Figure C-31b). The model is predicting elevated Soil concentrations in the OK-KS-MO-IA area that is not reflected in the measurements (Figure C-31c).

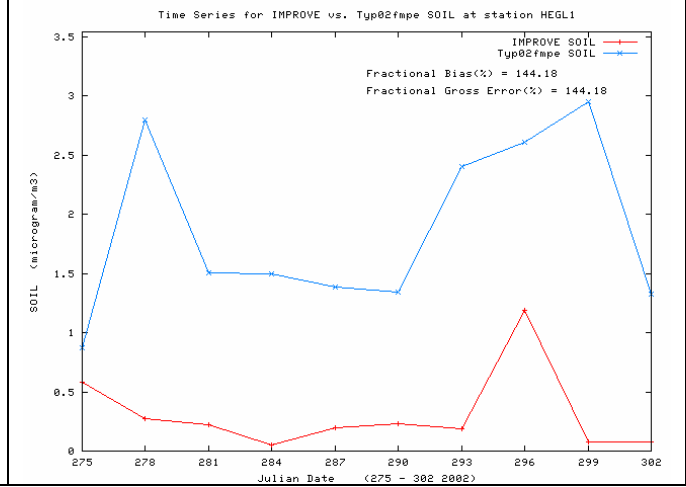

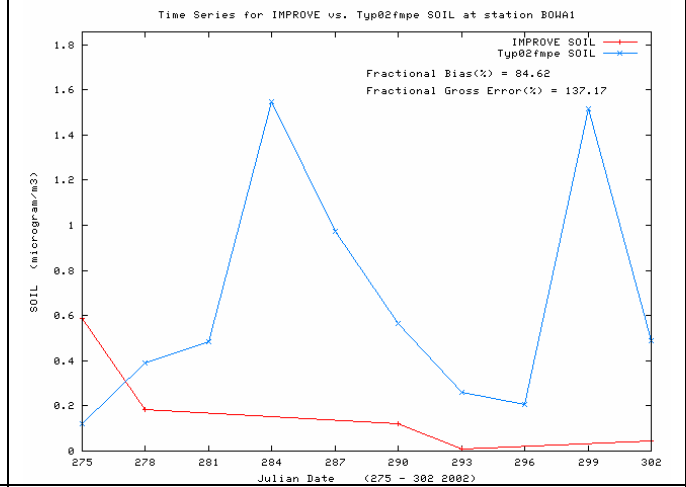

Figure C-31a. Scatter plots of predicted and observed other PM_{2.5} (Soil) concentrations for October 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-31b. Time series of predicted and observed 24-hour other PM_{2.5} (Soil) concentrations at CENRAP IMPROVE CLASS I AREA sites in October 2002 for CMAQ 2002 36 km Base F base case simulation.

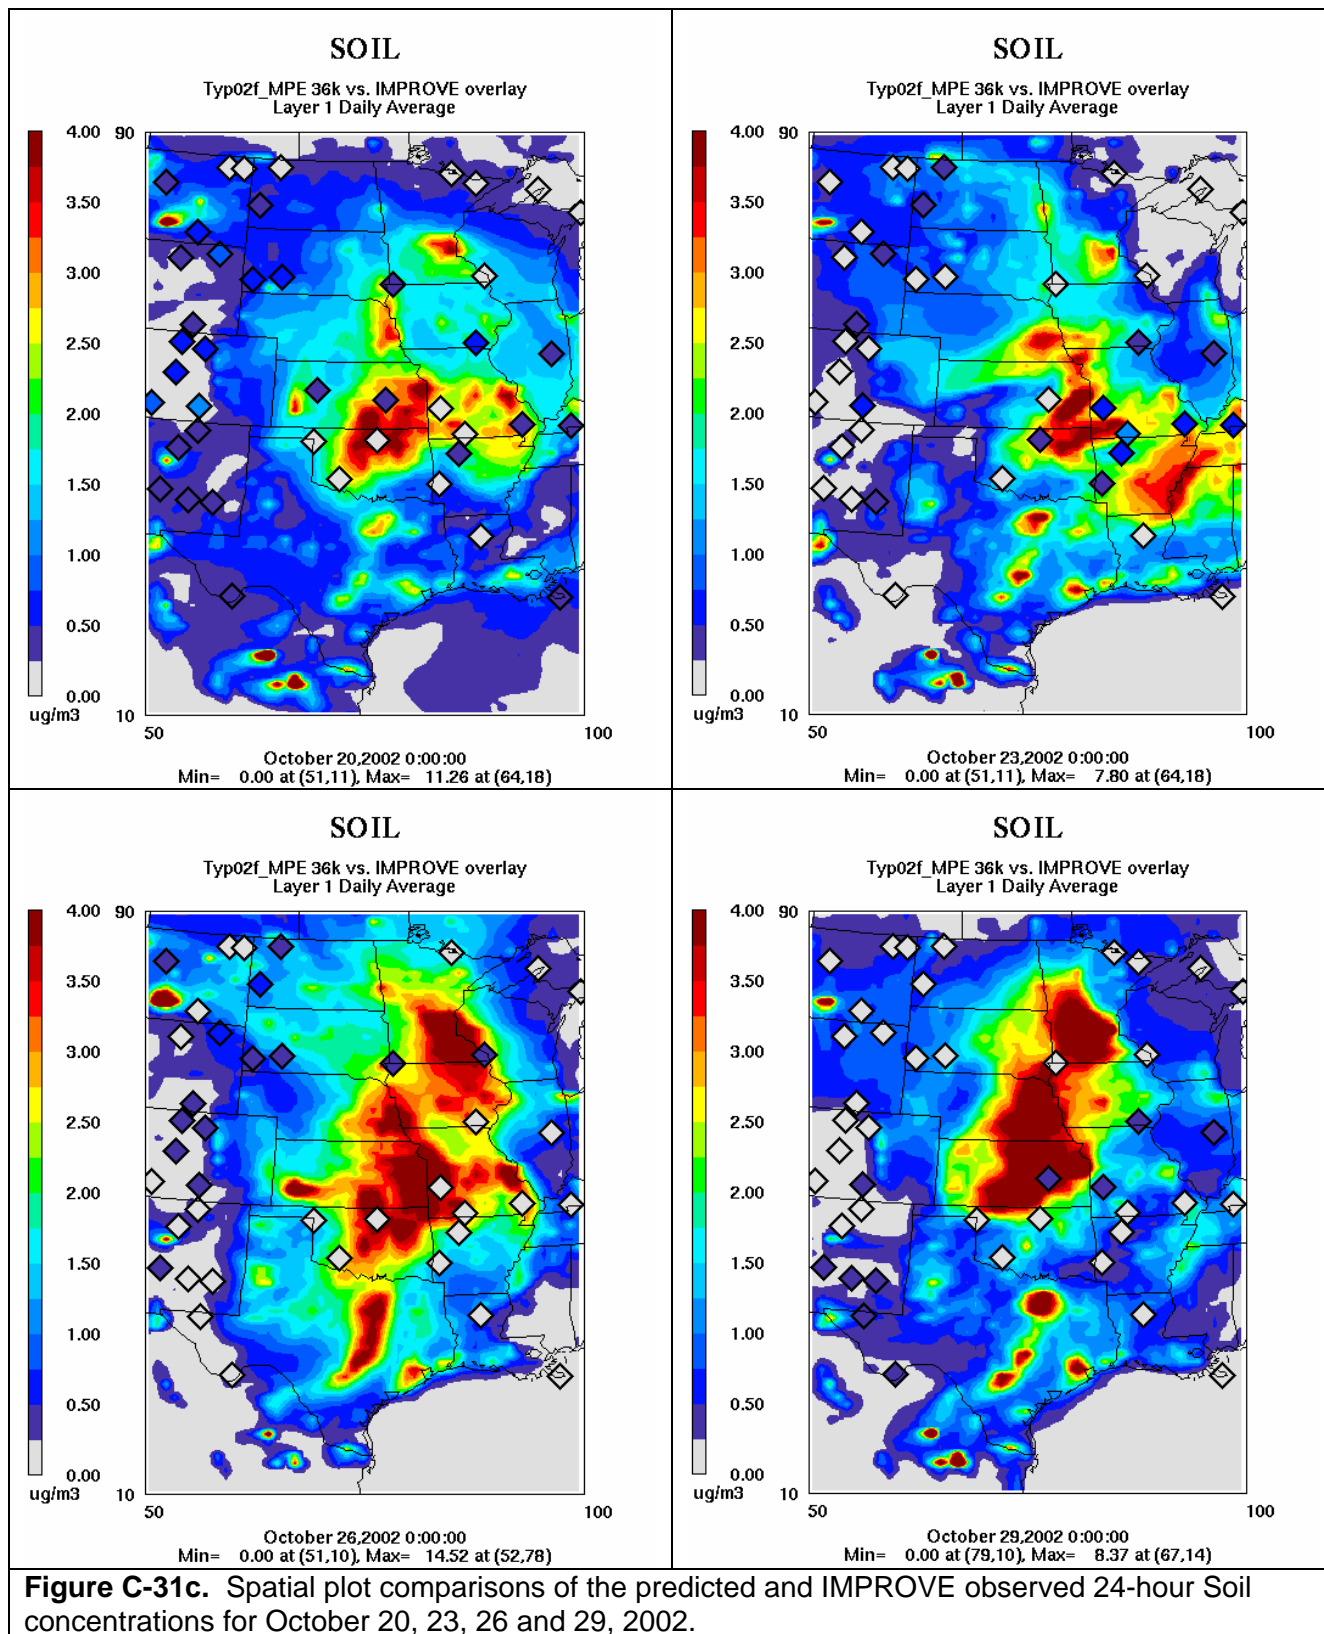

Figure C-31c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour Soil concentrations for October 20, 23, 26 and 29, 2002.

C.3.5.5 Soil Monthly Bias and Error

Figure C-32 displays the monthly variation in the Soil bias and error. During the winter months the model exhibits a very large (> 100%) overestimation bias with large errors as well. With the exception of July, in the summer the model bias is a slight over-prediction but generally less than 20% with errors of 60% to 80%. The Bugle Plot indicates that the summer Soil performance achieves the PM performance goal, a few months in the Spring/Fall period fall between the performance goal and criteria and the winter Soil performance exceeds the model performance criteria by a far margin. Thus, the Soil performance is a cause for concern.

SOIL

Figure C-33. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for Soil and IMPROVE monitoring sites in the CENRAP region.

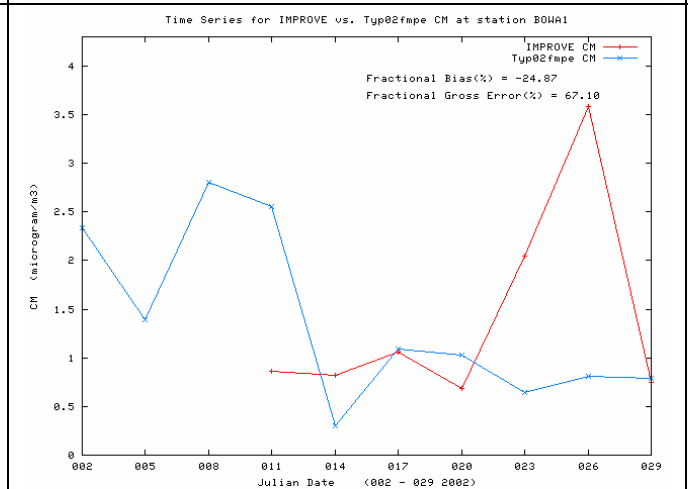

C.3.6 Coarse Mass (CM) Monthly Model Performance

The IMPROVE coarse mass (CM) measurement is taken as the difference between the PM_{10} and $PM_{2.5}$ mass measurement. Any SO_4 or NO_3 in the coarse mode will be in the CM measurement. The model, on the other hand, only includes primary CM. Any coarse SO_4 or NO_3 will be in the SO_4 and NO_3 modeled species.

C.3.6.1 CM in January 2002

The model underestimates the observed CM in January with a fractional bias of -83% (Figure C-34a). Although the model appears to reproduce CM at some sites (e.g., VOYA) at the two Texas sites the bias is approximately -150% (Figure C-34b). The observed spatial distribution of CM in January is not reproduced by the model at all (Figure C-34c). Whereas the observations indicate high CM concentrations in the west Texas-New Mexico area, the model estimates elevated CM in northeast Texas, through Oklahoma, Kansas, Iowa and into southern Minnesota. Although the CM measurements at WIMO in this area are also elevated, the rest of the high modeled CM values fall between the IMPROVE monitors so can not be verified or refuted by the measurements.

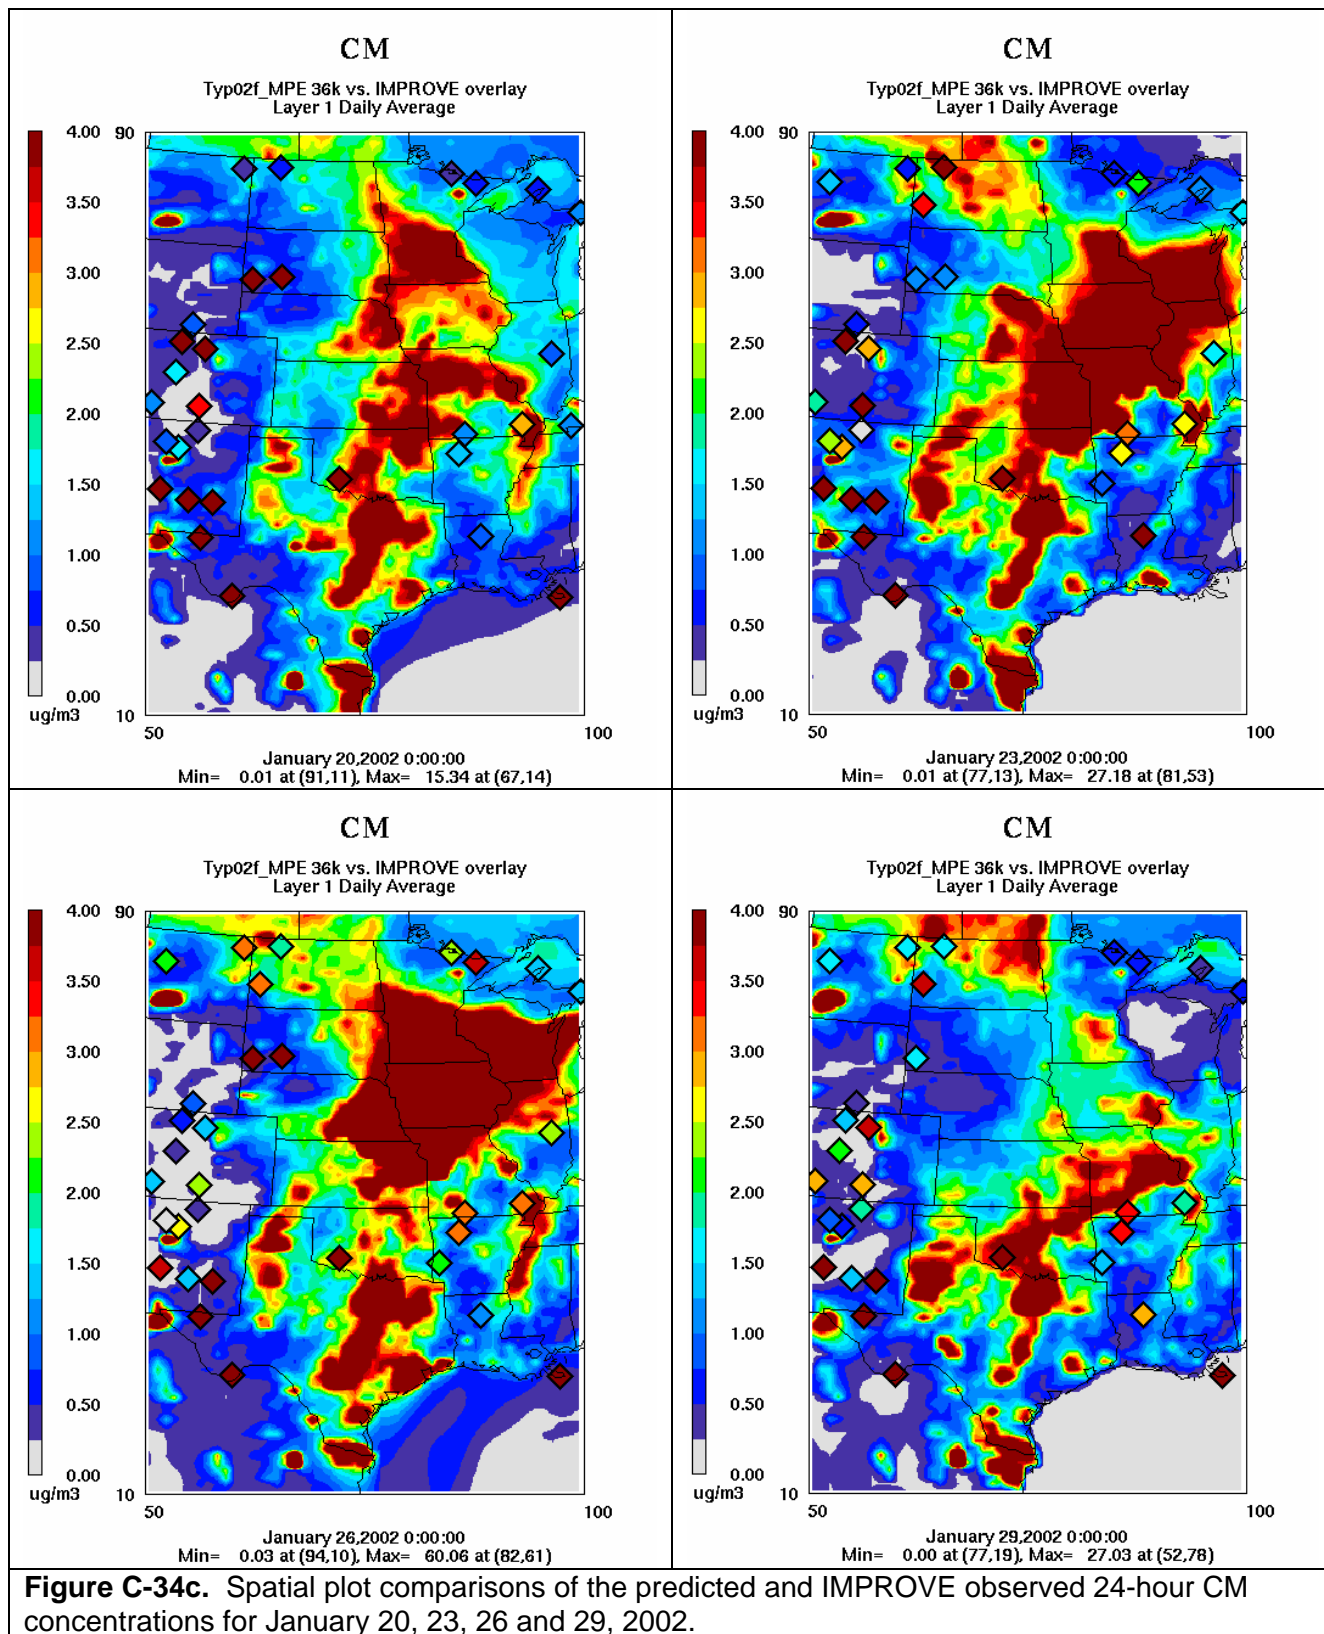

Figure C-34b. Time series of predicted and observed 24-hour coarse mass (CM) concentrations at CENRAP IMPROVE CLASS I AREA sites in January 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.6.2 CM in April 2002

The CM underestimation bias is even greater in April (-137%) and occurs at all IMPROVE sites (Figure C-35).

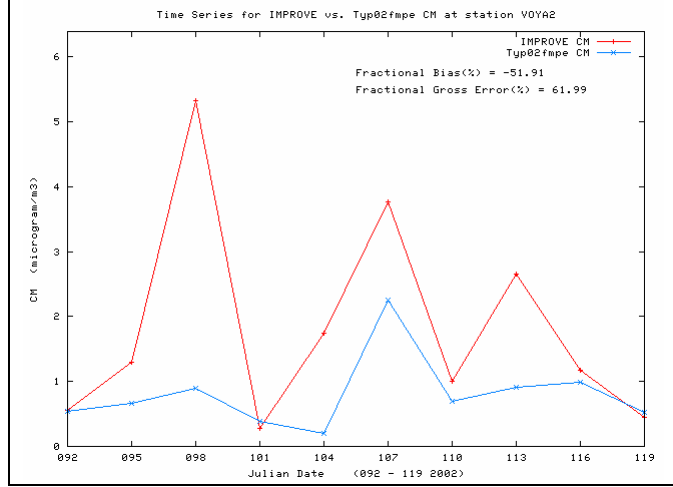

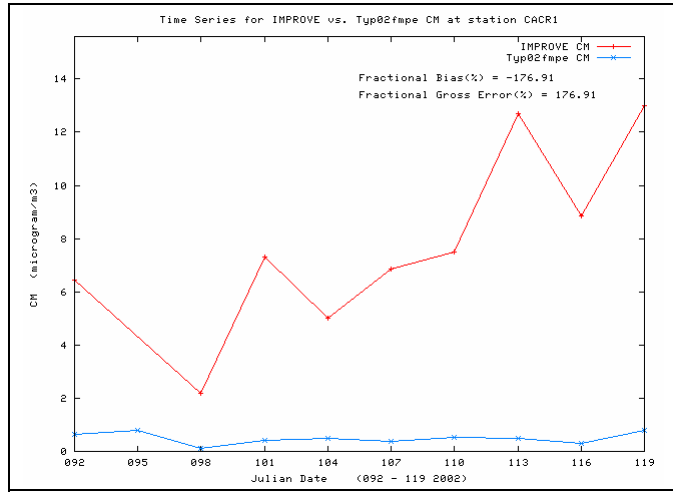

Figure C-35a. Scatter plots of predicted and observed coarse mass (CM) concentrations for April 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-35b. Time series of predicted and observed 24-hour coarse mass (CM) concentrations at CENRAP IMPROVE CLASS I AREA sites in April 2002 for CMAQ 2002 36 km Base F base case simulation.

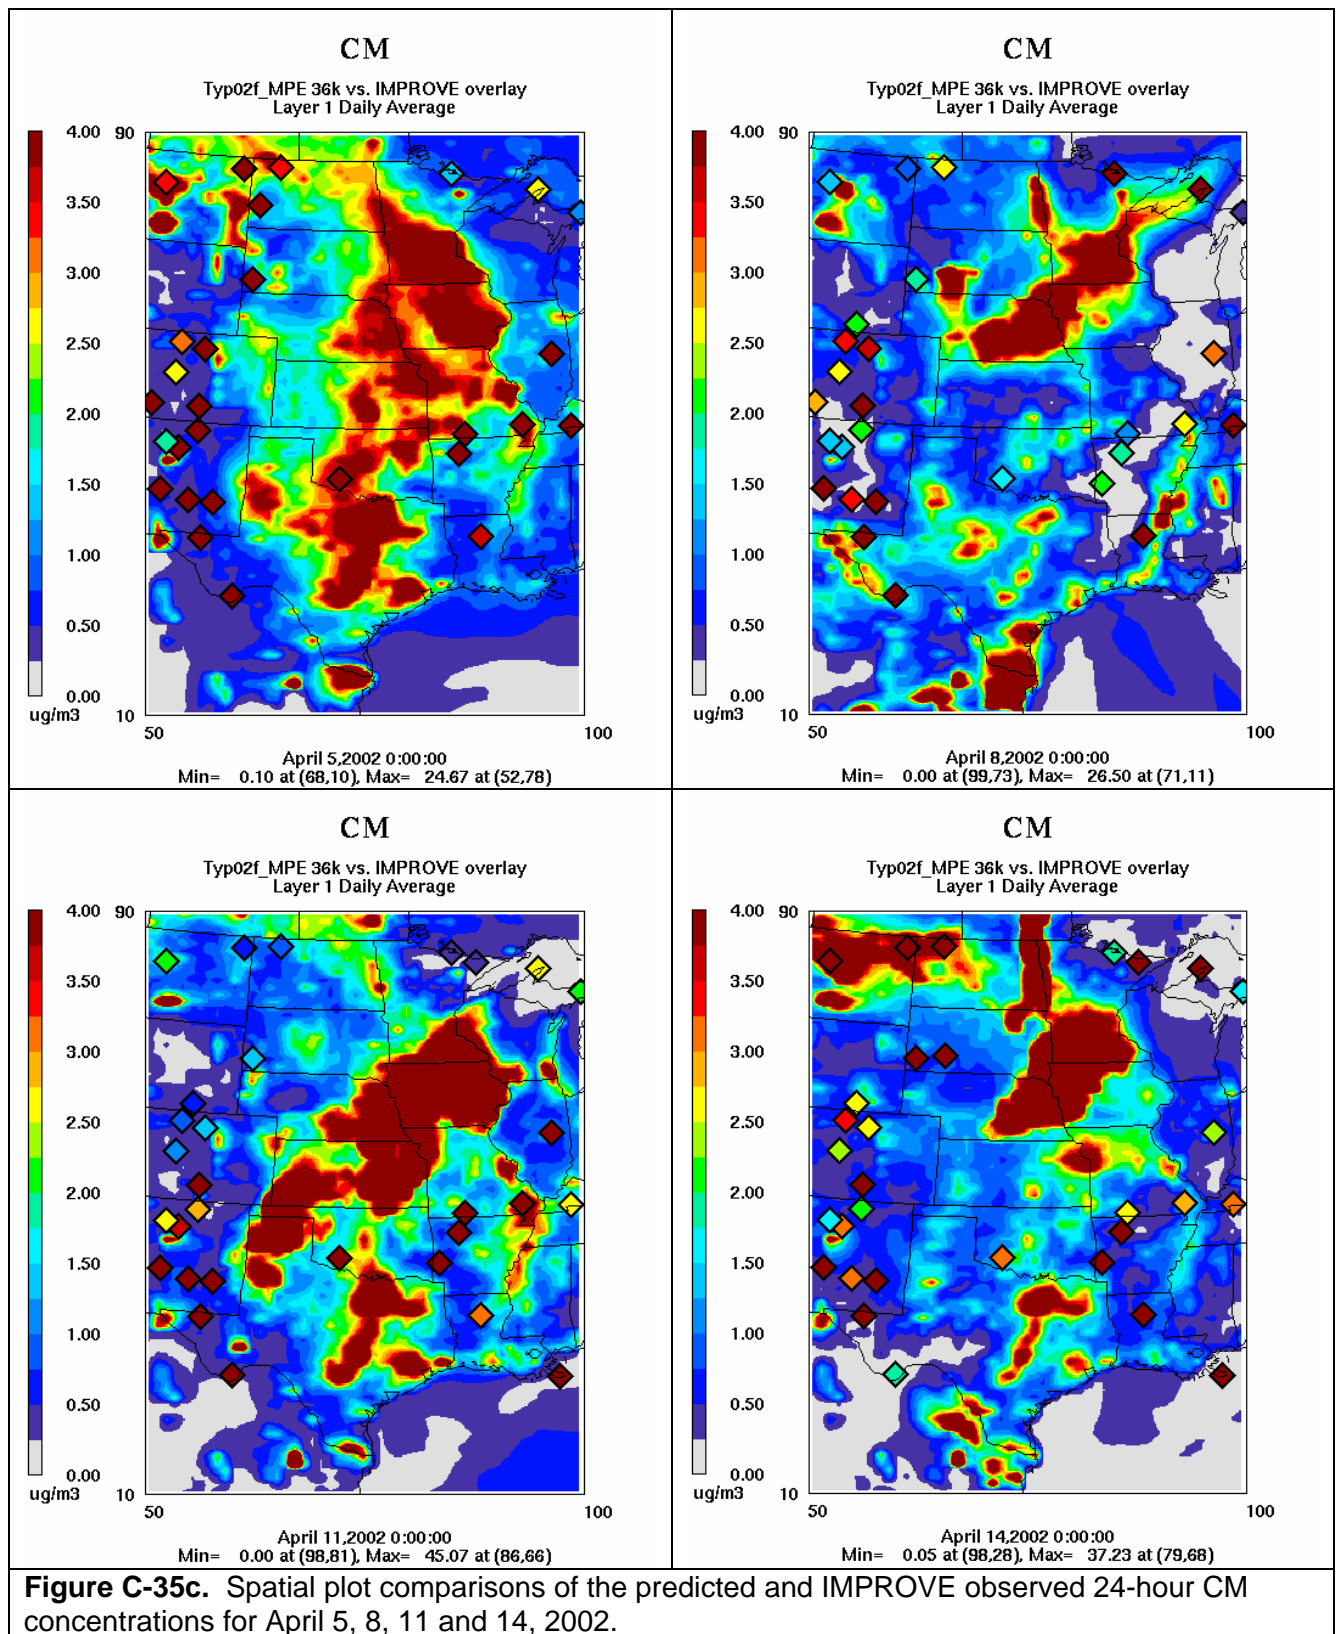

Figure C-35c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour CM concentrations for April 5, 8, 11 and 14, 2002.

C.3.6.3 CM in July 2002

CM performance in July is also very poor with a fractional bias value of -160% (Figure C-36).

Figure C-36a. Scatter plots of predicted and observed coarse mass (CM) concentrations for July 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

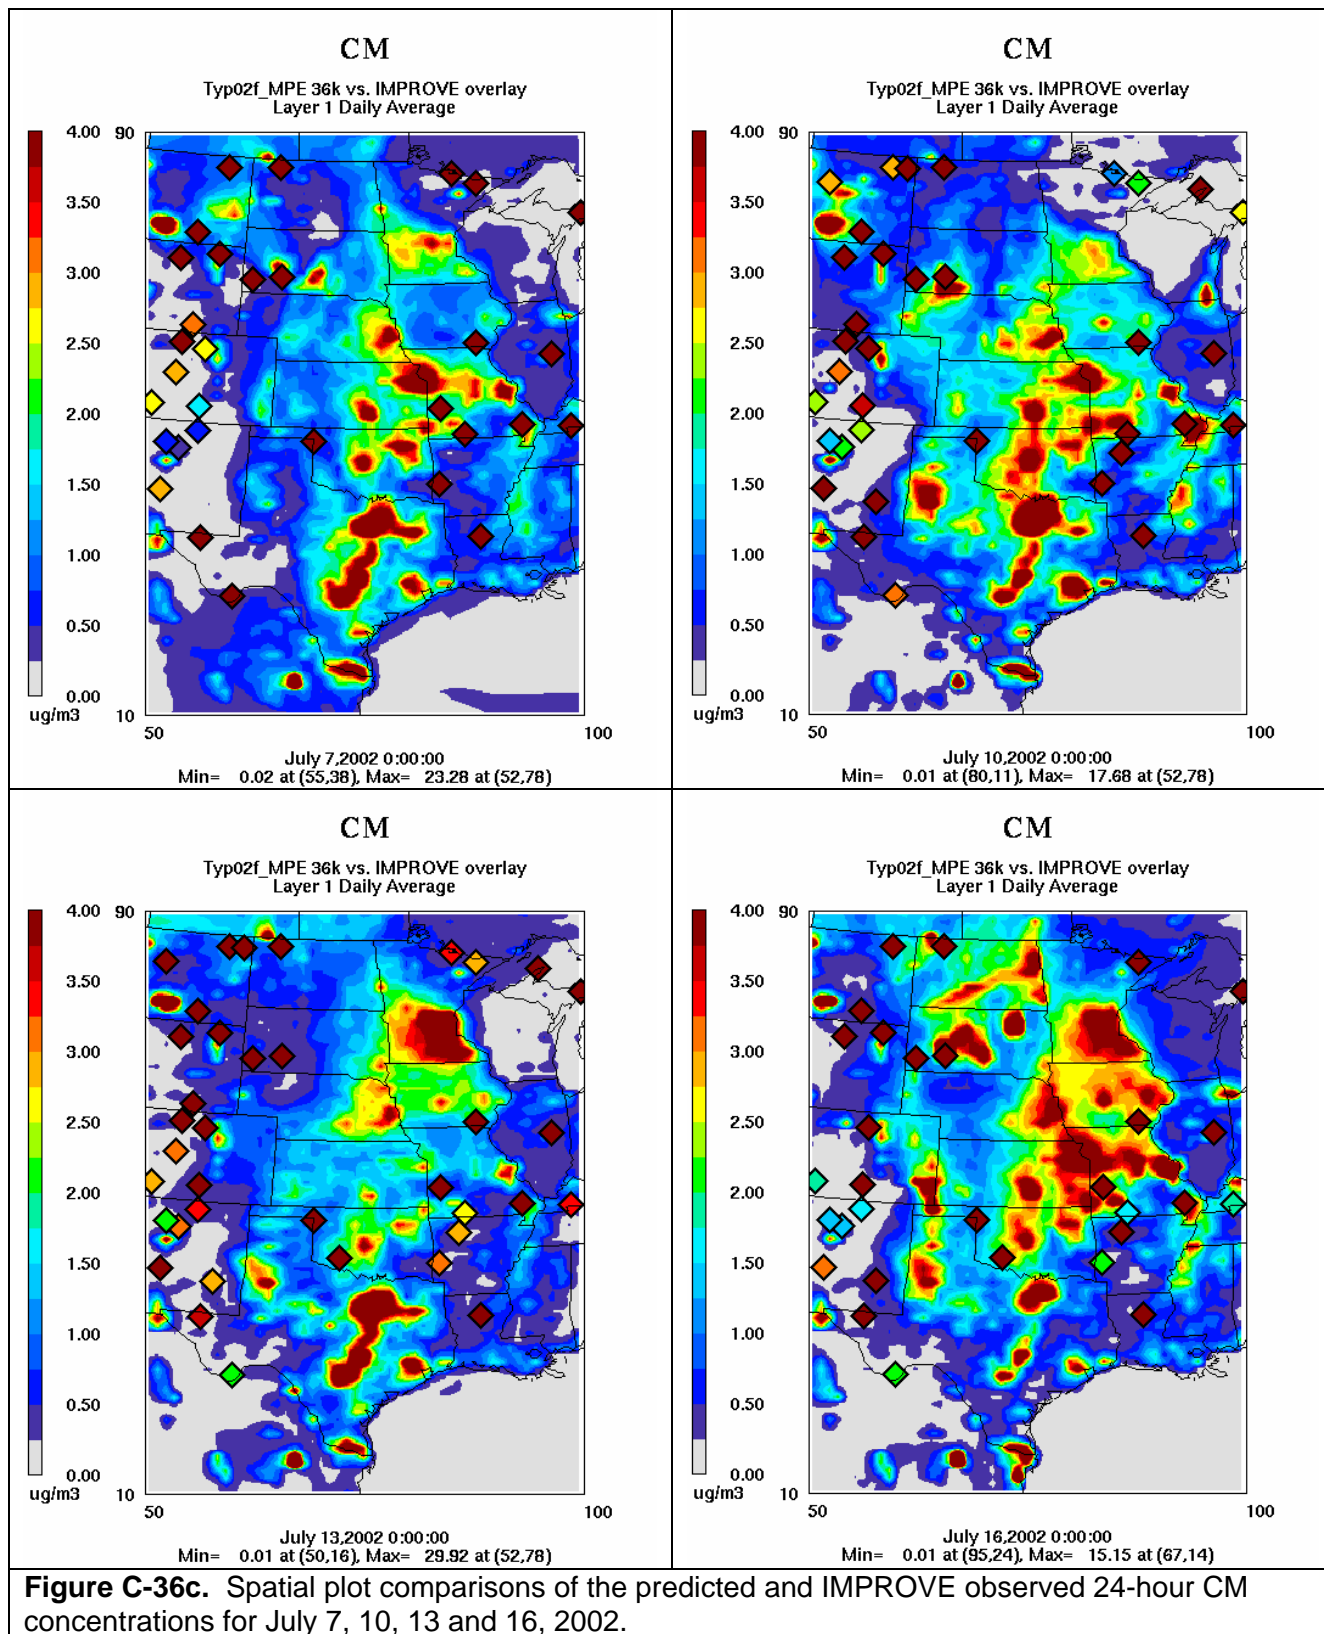

Figure C-36b. Time series of predicted and observed 24-hour coarse mass (CM) concentrations at CENRAP IMPROVE CLASS I AREA sites in July 2002 for CMAQ 2002 36 km Base F base case simulation.

C.3.6.4 CM in October 2002

CM is also underestimated in October, although the overestimation bias (-72%) is not as great as seen in July (Figure C-37).

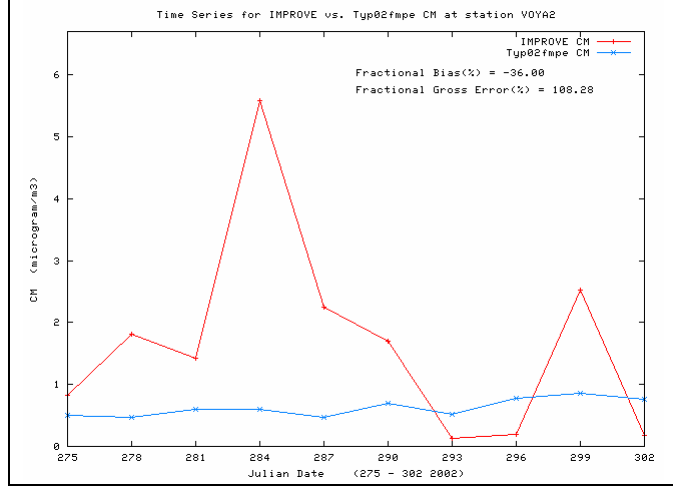

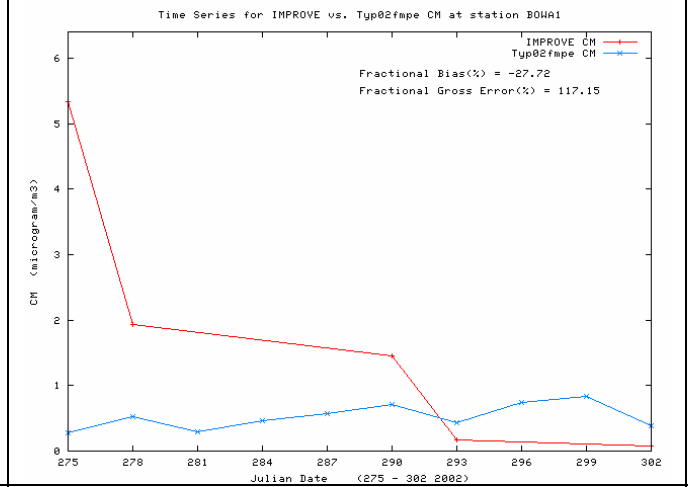

Figure C-37a. Scatter plots of predicted and observed coarse mass (CM) concentrations for October 2002 and sites in the CENRAP region using IMPROVE monitoring networks using the CMAQ 2002 36 km Base F base case simulation.

Figure C-37b. Time series of predicted and observed 24-hour coarse mass (CM) concentrations at CENRAP IMPROVE CLASS I AREA sites in October 2002 for CMAQ 2002 36 km Base F base case simulation.

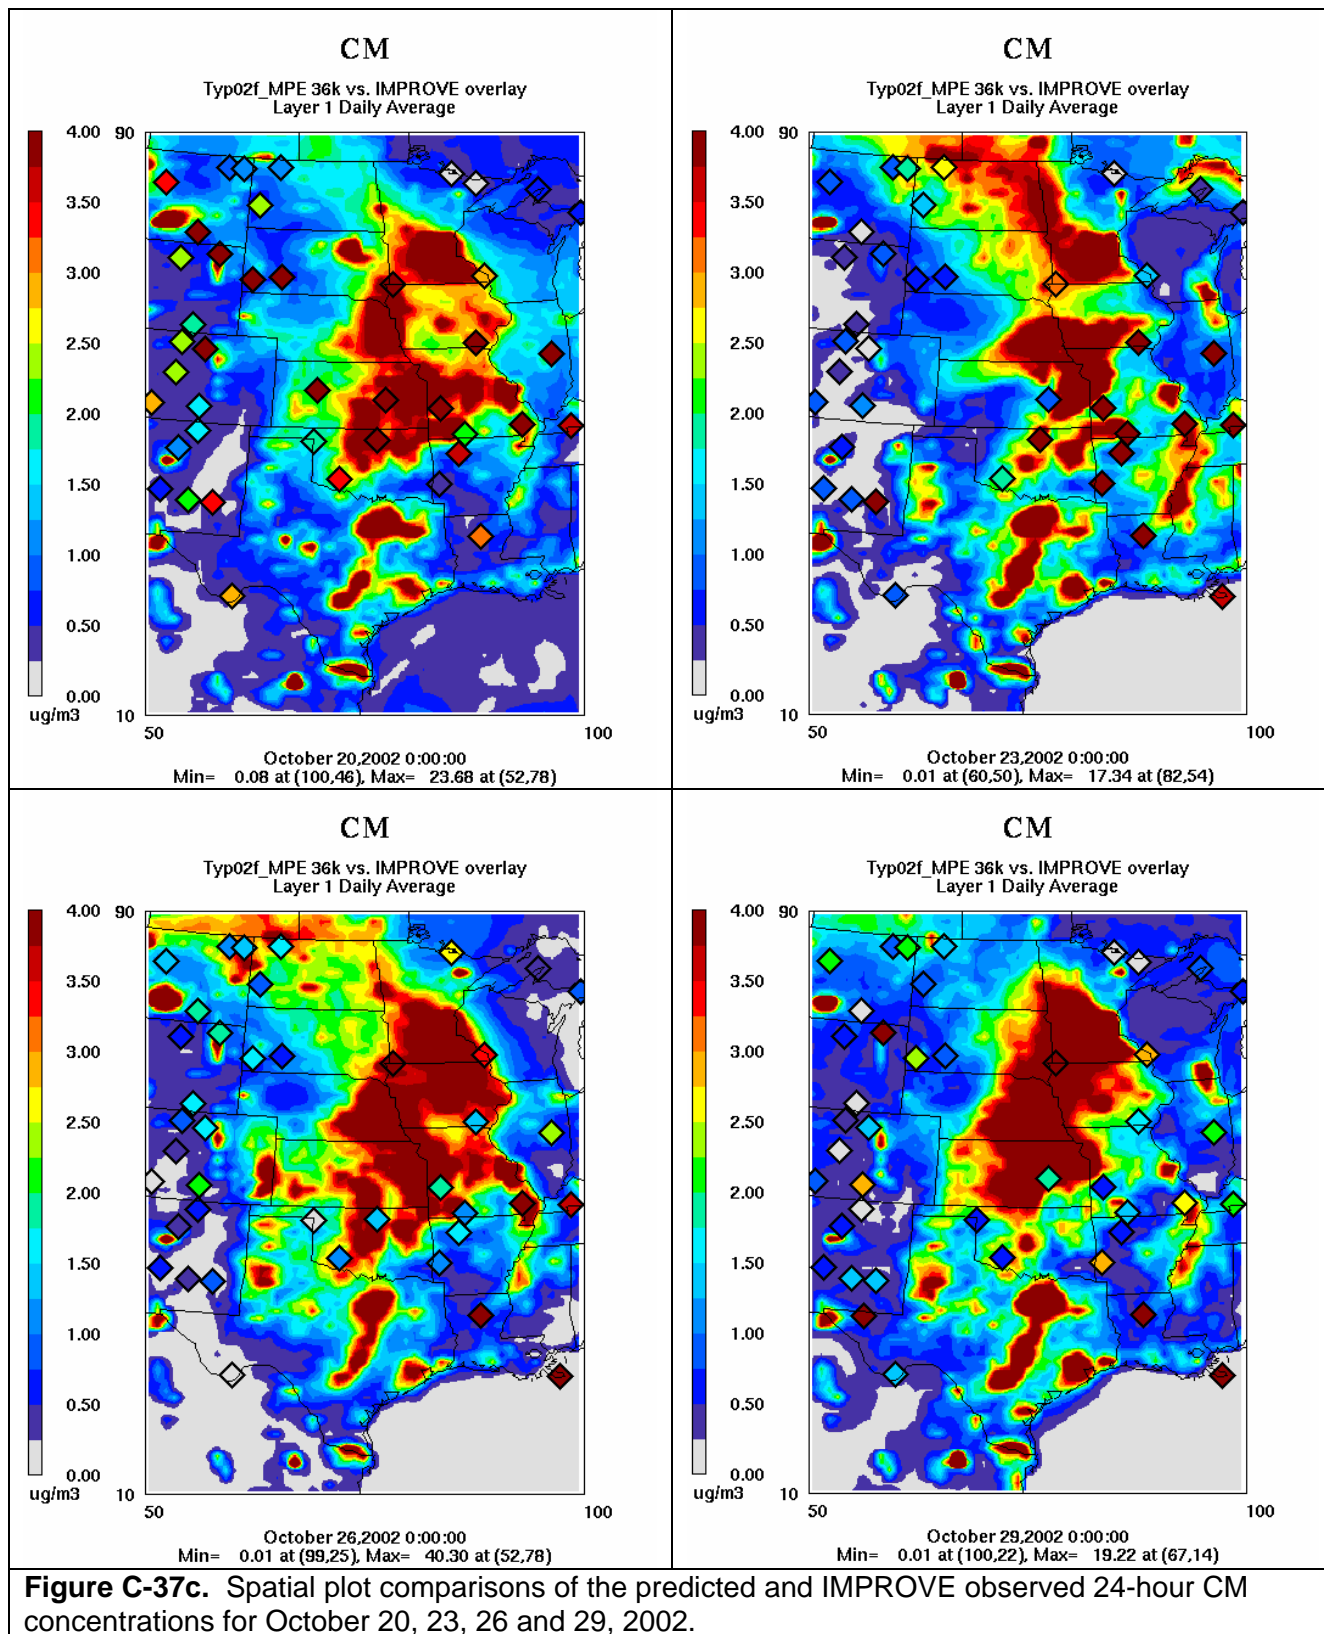

Figure C-37c. Spatial plot comparisons of the predicted and IMPROVE observed 24-hour CM concentrations for October 20, 23, 26 and 29, 2002.

C.3.6.5 CM Monthly Bias and Error

The monthly average fractional bias and error values for CM are shown in Figure C-38. In the winter the under-prediction bias is typically in the -60% to -80% range. In the late Spring and Summer the under-prediction bias ranges from -120% to -160%. As this under-prediction bias is nearly systematic, then the errors are the same magnitude as the bias.

The Bugle Plots clearly show that the CM model performance is a problem. The monthly bias exceeds both the performance goal and criteria for almost every month of the year. The error criteria are also exceeded for all months of the year.

Figure C-38. Monthly CM fractional bias (top) and fractional gross error (bottom) statistical measures for IMPROVE monitoring sites in the CENRAP region.

CENRAP Typ02f_MPE 36k Bugle Plot

CM

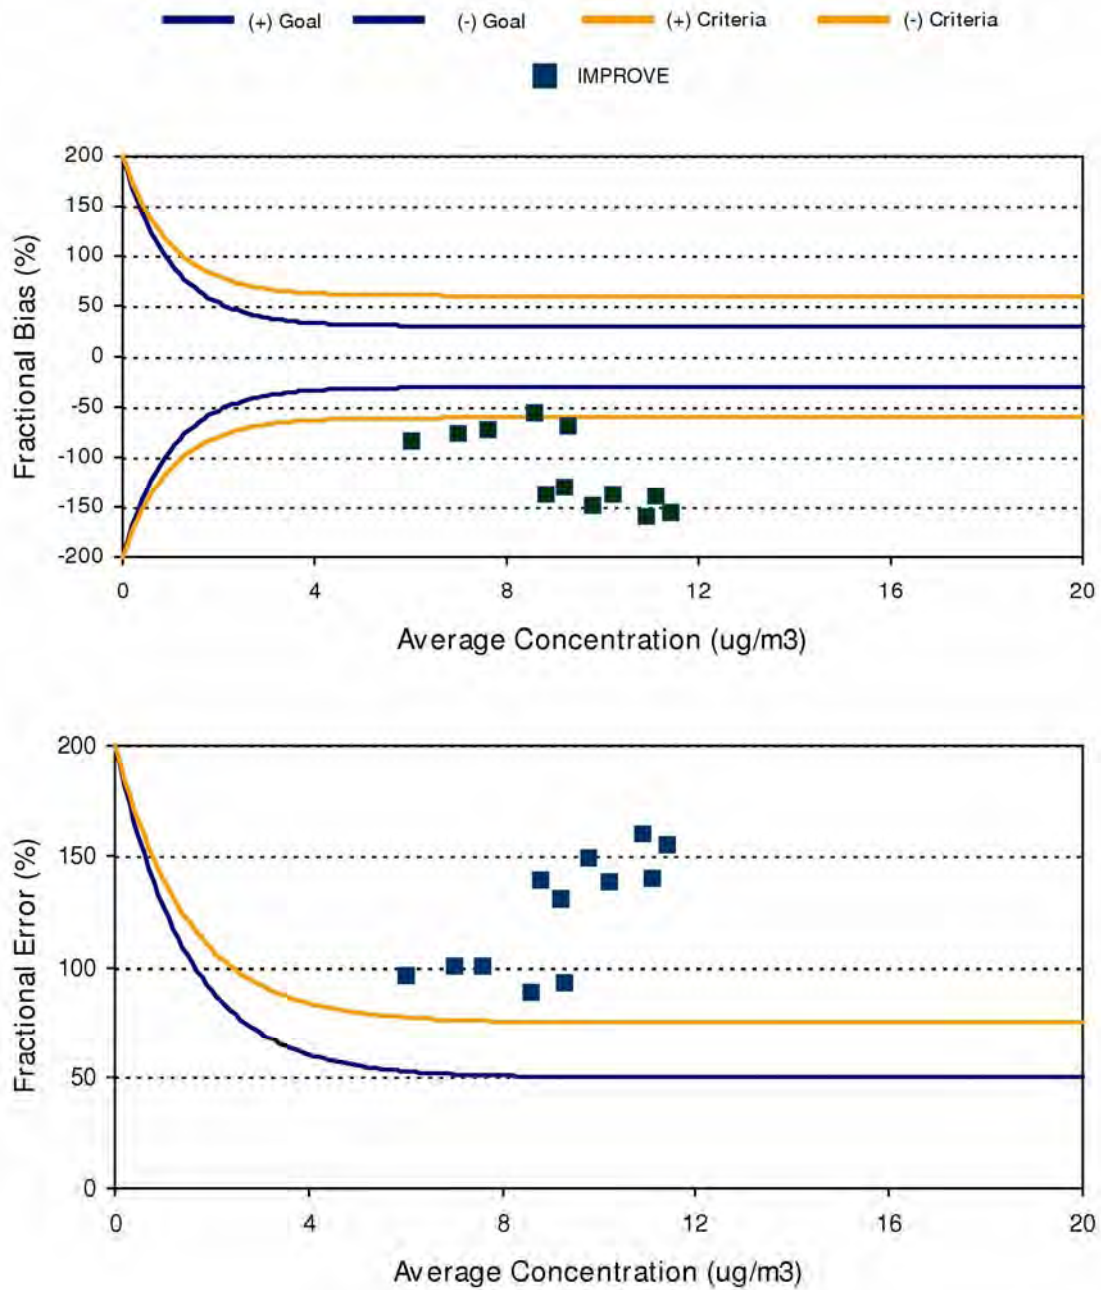

Figure C-39. Bugle Plots of monthly fractional bias (top) and fractional gross error (bottom) and comparisons with model performance goals and criteria for CM and IMPROVE monitoring sites in the CENRAP region.

C.4 Diagnostic Model Evaluation for Gas-Phase and Precursor Species

The CASTNet and AQS networks also measure gas-phase species that are PM precursor or related species. The diagnostic evaluation of the 2002 36 km Base F CMAQ base case simulation for these compounds and the four seasonal months presented previously is provided below.

The CASTNet network measures weekly average samples of SO₂, SO₄, NO₂, HNO₃, NO₃ and NH₄. The AQS network collects hourly measurements of SO₂, NO₂, O₃ and CO. A comparison of the SO₂ and SO₄ performance provides insight into whether the SO₄ formation rate may be too slow or fast. For example, if SO₄ is underestimated and SO₂ is overestimated that may indicate too slow chemical conversion rate. Analyzing the performance for SO₄, HNO₃, NO₃, Total NO₃ and NH₄ provides insight into the equilibrium of these species. For example, if Total NO₃ performs well but HNO₃ and NO₃ do not, then there may be issues associated with the partitioning between the gaseous and particle phases of nitrate.

C.4.1 Diagnostic Model Performance in January 2002

In January, SO₂ is overstated across both the CASTNet and AQS sites with fractional bias values of 38% (Figure C-40) and 31% (Figure C-41), respectively. SO₄ is understated by -34% across the CASTNet monitors (Figure C-40) and -12% and -13% for the IMPROVE and STN networks (Figure C-4a). As noted previously, wet SO₄ deposition is also overstated in January (+40%, Figure C-4a). Given that SO₂ emissions are well characterized, these results suggest that the January SO₄ underestimation may be partly due to understated transformation rates of SO₂ to SO₄ and overstated wet SO₄ deposition.

Total NO₃ is overestimated by 35% on average across the CASTNet sites in the CENRAP region in January (Figure C-40). HNO₃ is underestimated (-34%) and particle NO₃ is overestimated (+61%) suggesting there are gas/particle equilibrium issues. An analysis of the time series of the four CASTNet stations reveals that NO₃, HNO₃ and NH₄ performance is actually very reasonable at the west Texas and the HNO₃ underestimation and NO₃ overestimation bias is coming from the east Kansas, central Arkansas and northern Minnesota CASTNet sites. One potential contributor for this performance problem is overstated NH₃ emissions. However the overstated Total NO₃ suggests that the model estimated NO_x oxidation rate may be too high in January.

The SO₂, NO₂, O₃ and CO performance across the AQS sites in January is shown in Figure C-41. The AQS monitoring network is primarily an urban-oriented network so it is not surprising that the model is underestimating concentrations of primary emissions like NO₂ (-5%) and particularly CO (-67%) when a 36 km grid is used. Ozone is also underestimated on average, especially the maximum values above 60 ppb.

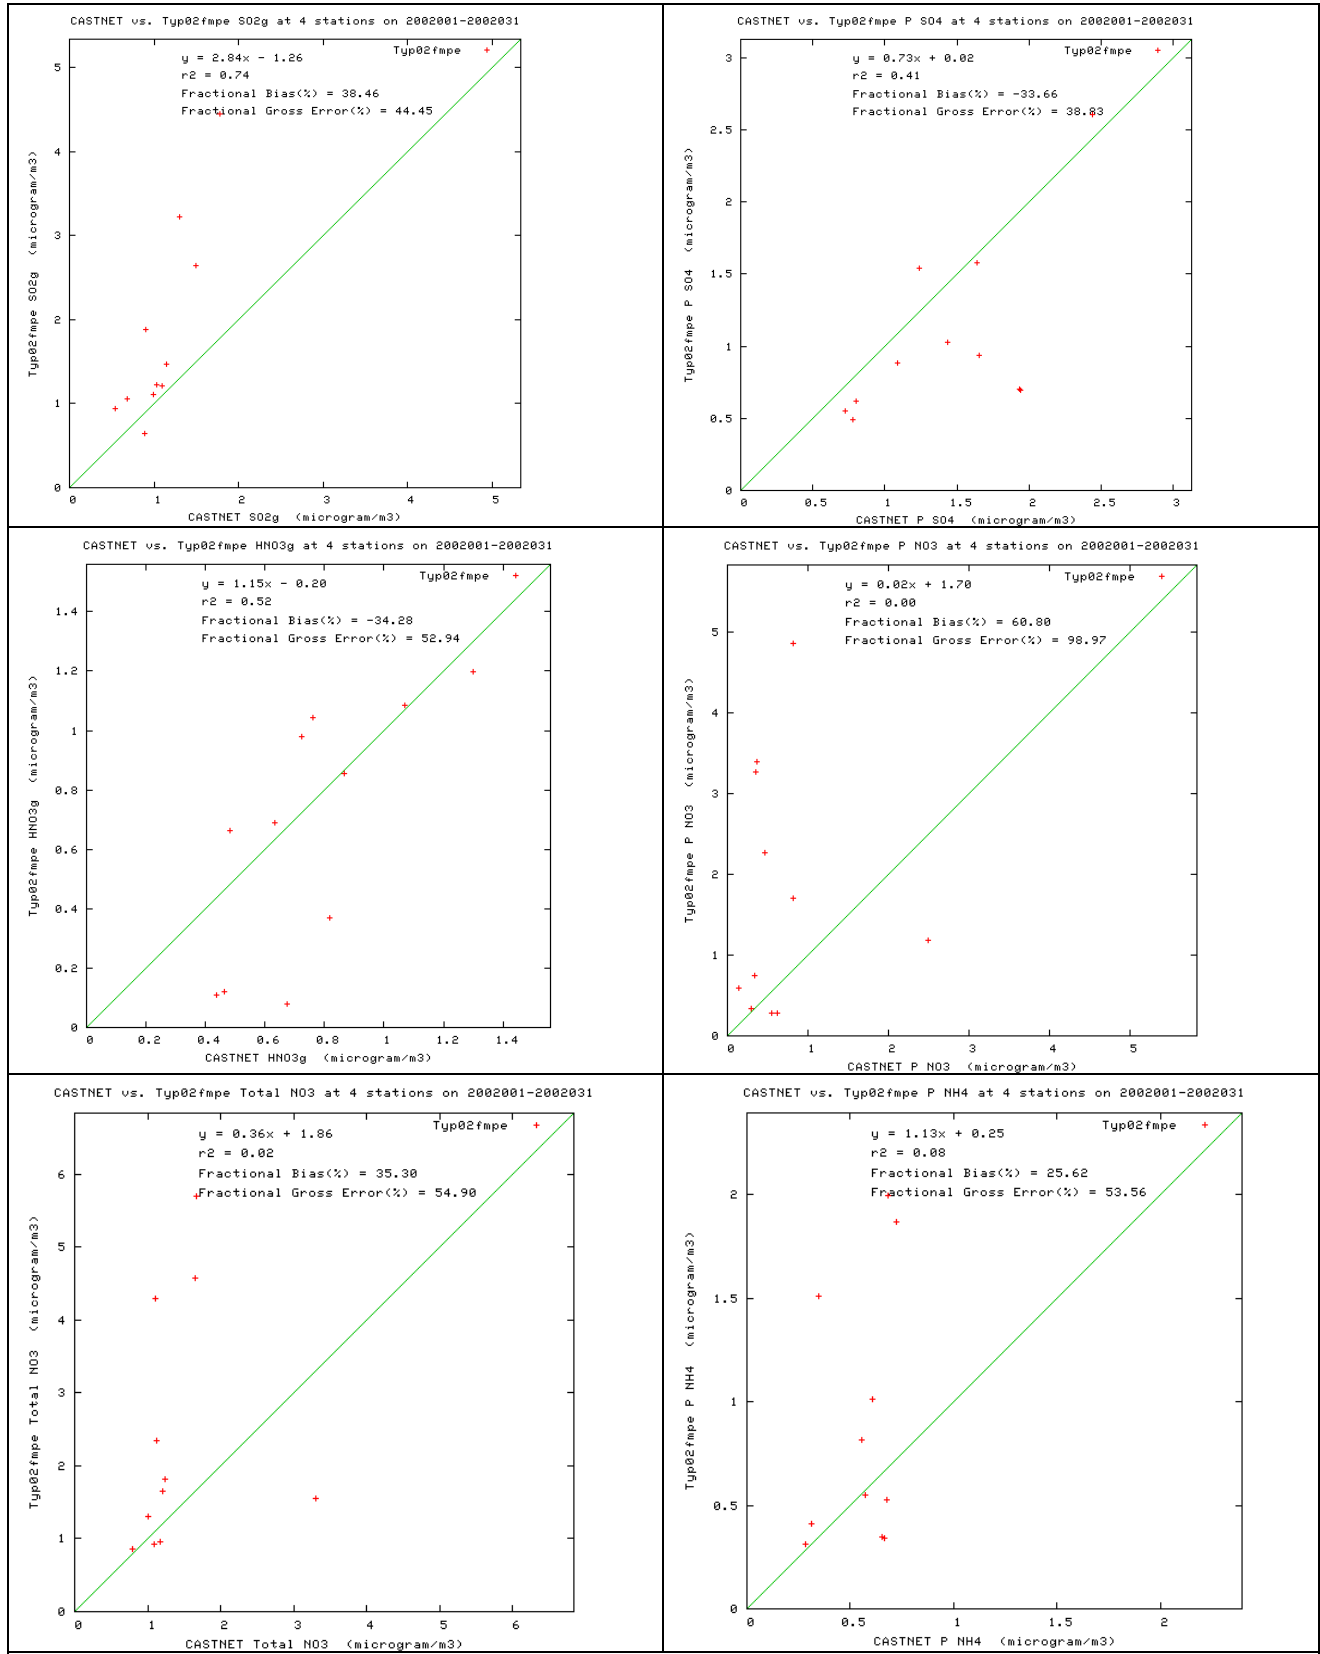

Figure C-40. January 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Ttotal NO3 (bottom left) and NH4 (bottom right).

Figure C-41. January 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.4.2 Diagnostic Model Performance In April

In April there is an average SO₂ overestimation bias across the CASTNet (+15%) and underestimation bias across the AQS (-10%) networks (Figures C-42 and C-43). SO₄ is underestimated across all networks by -30% to -58% (Figure C-5a). The wet SO₄ deposition bias is near zero. Both SO₂ and SO₄ are underestimated at the west Texas CASTNet monitor in April suggesting SO₂ emissions in Mexico are likely understated.

The HNO₃ performance in April is interesting with almost perfect agreement except for 5 modeled-observed comparisons that drives the average under-prediction bias of -29%. On Julian Day 102 there is high HNO₃ at the MN, KS and OK CASTNet sites that is not captured by the model. Given that HNO₃, NO₃ and Total NO₃ are all underestimated by about the same amount (-30%), then part of the underestimation bias is likely due to too slow oxidation of NO_x.

There is a lot of scatter in the NO₂ and O₃ performance that is more or less centered on the 1:1 line of perfect agreement with bias values of -8% and -21%, respectively (Figure C-43). CO is underestimated by -72% with the model unable to predict CO concentrations above 1 µg/m³ due to the use of the coarse 36 km grid spacing. Mobile sources produce a vast majority of the CO emissions so AQS monitors for CO compliance are located near roadways, which are not simulated well using a 36 km grid.

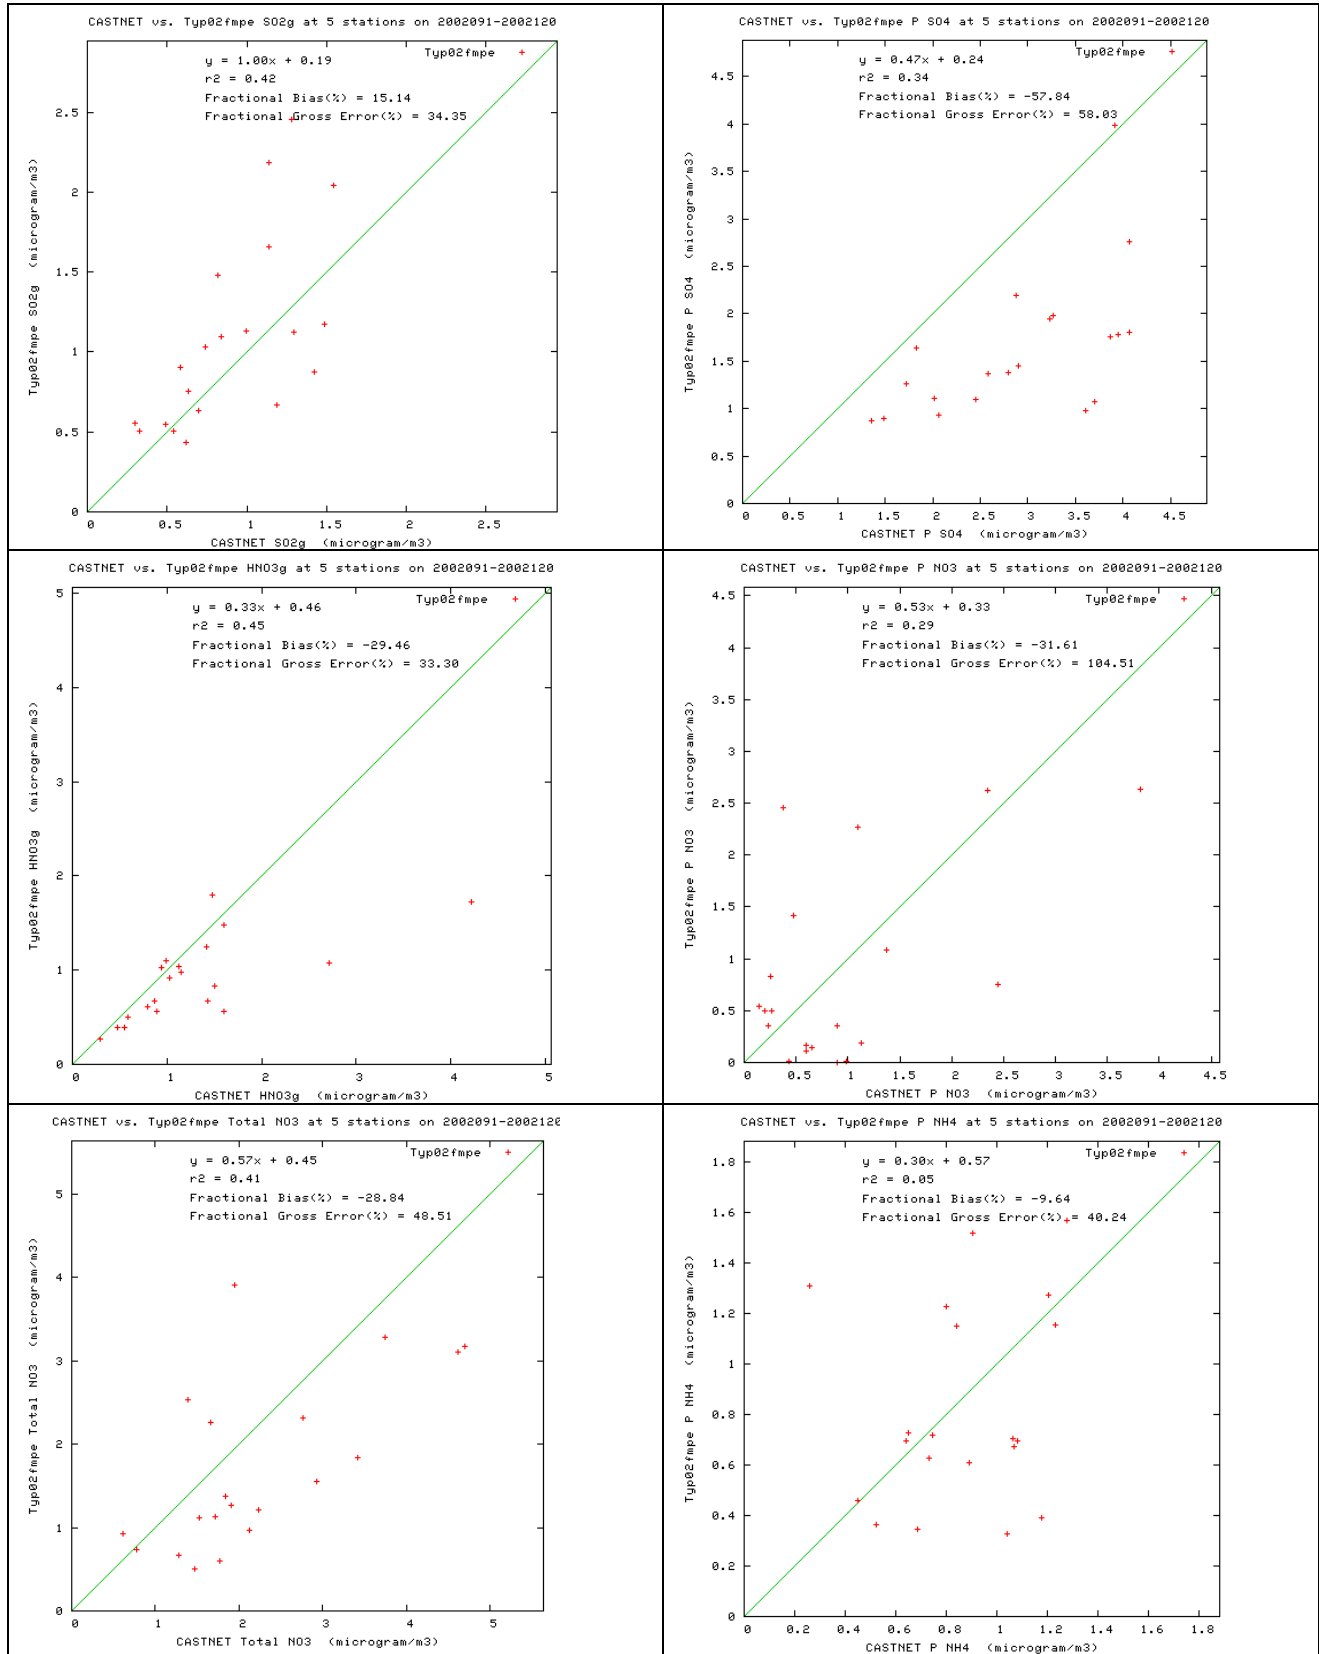

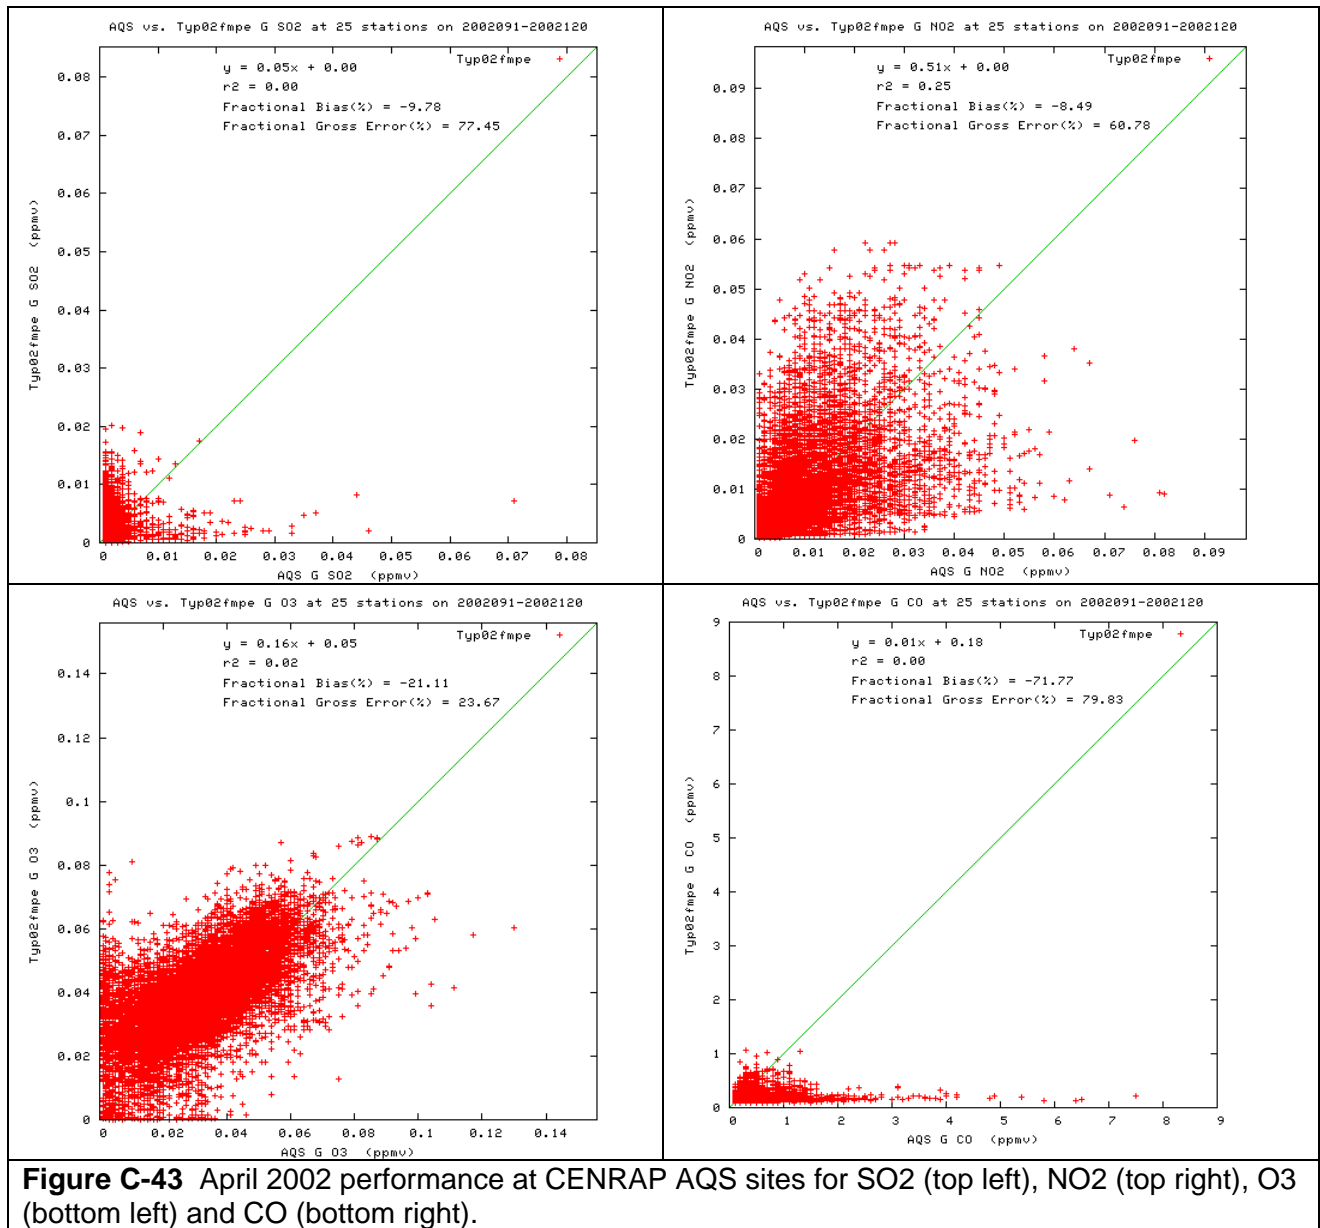

Figure C-42 April 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

C.4.3 Diagnostic Model Performance In July

In July SO₂ is slightly underestimated across the CASTNet (-5%) and AQS (-12%) networks (Figures C-44 and C-45) and SO₄ is more significantly underestimated across all networks (-22% to -53%, Figure C-6a). Since wet SO₄ is also underestimated it is unclear the reasons for why all sulfur species are underestimated.

The nitrate species are also all underestimated with the Total NO₃ bias (-56%) being between the HNO₃ bias (-35%) and NO₃ bias (-115%). The modeled NO₃ values are all near zero with little correlation with the observations, whereas the observed HNO₃ and Total NO₃ is tracked well with correlation coefficients of 0.74 and 0.76. These results suggest that the July NO₃ model performance problem is partly due to insufficient formation of Total NO₃ and mainly due to too little incorrect partitioning of the Total NO₃ into the particle NO₃.

Again there is lots of scatter in the AQS NO₂ scatter plot for July (Figure C-45) resulting in a low bias (0%) but high error (65%). Ozone performance also exhibits a low bias (-15%) and error (20%), but the model is incapable of simulating ozone above 100 ppb. Although CO performance in July is better than the previous months, it still has a large underestimation bias (-82%).

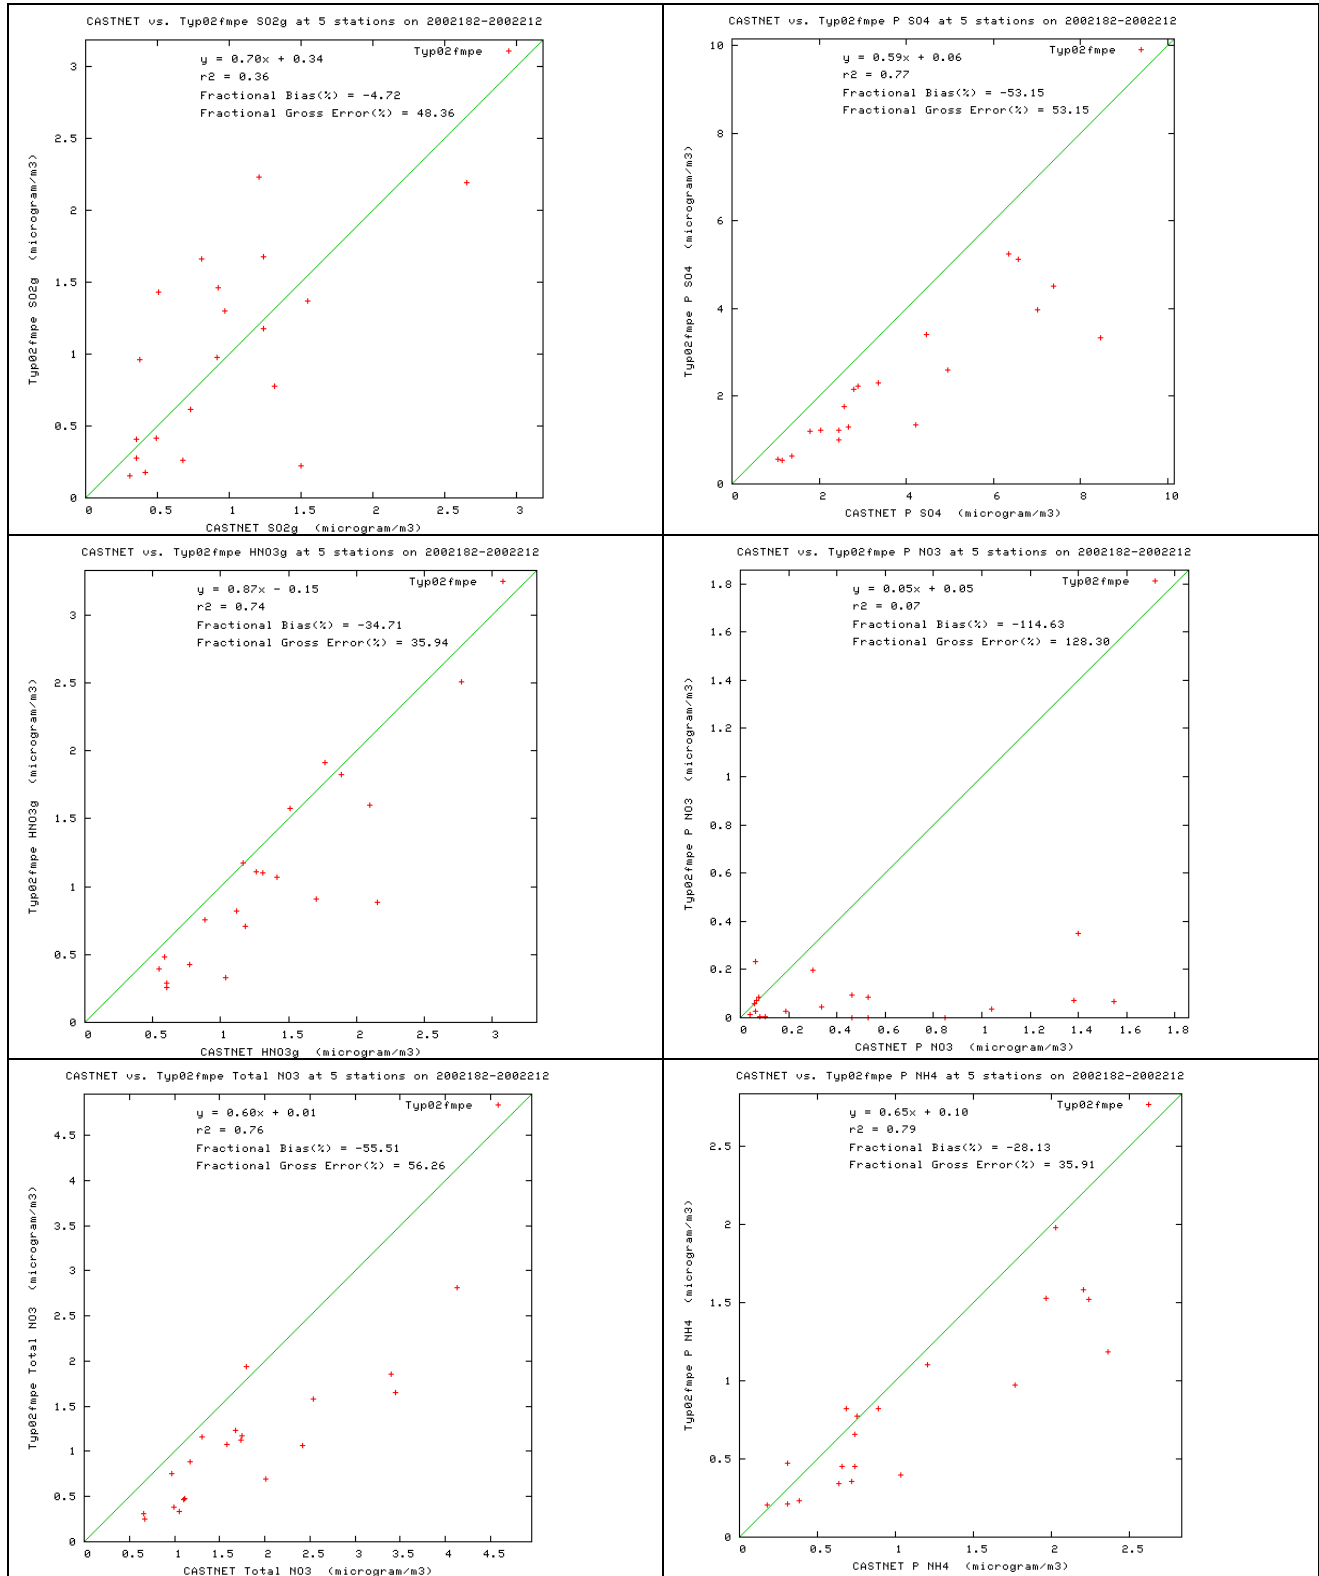

Figure C-44 July 2002 performance at CENRAP CASTNet sites for SO2 (top left), SO4 (top right), HNO3 (middle left), NO3 (middle right), Total NO3 (bottom left) and NH4 (bottom right).

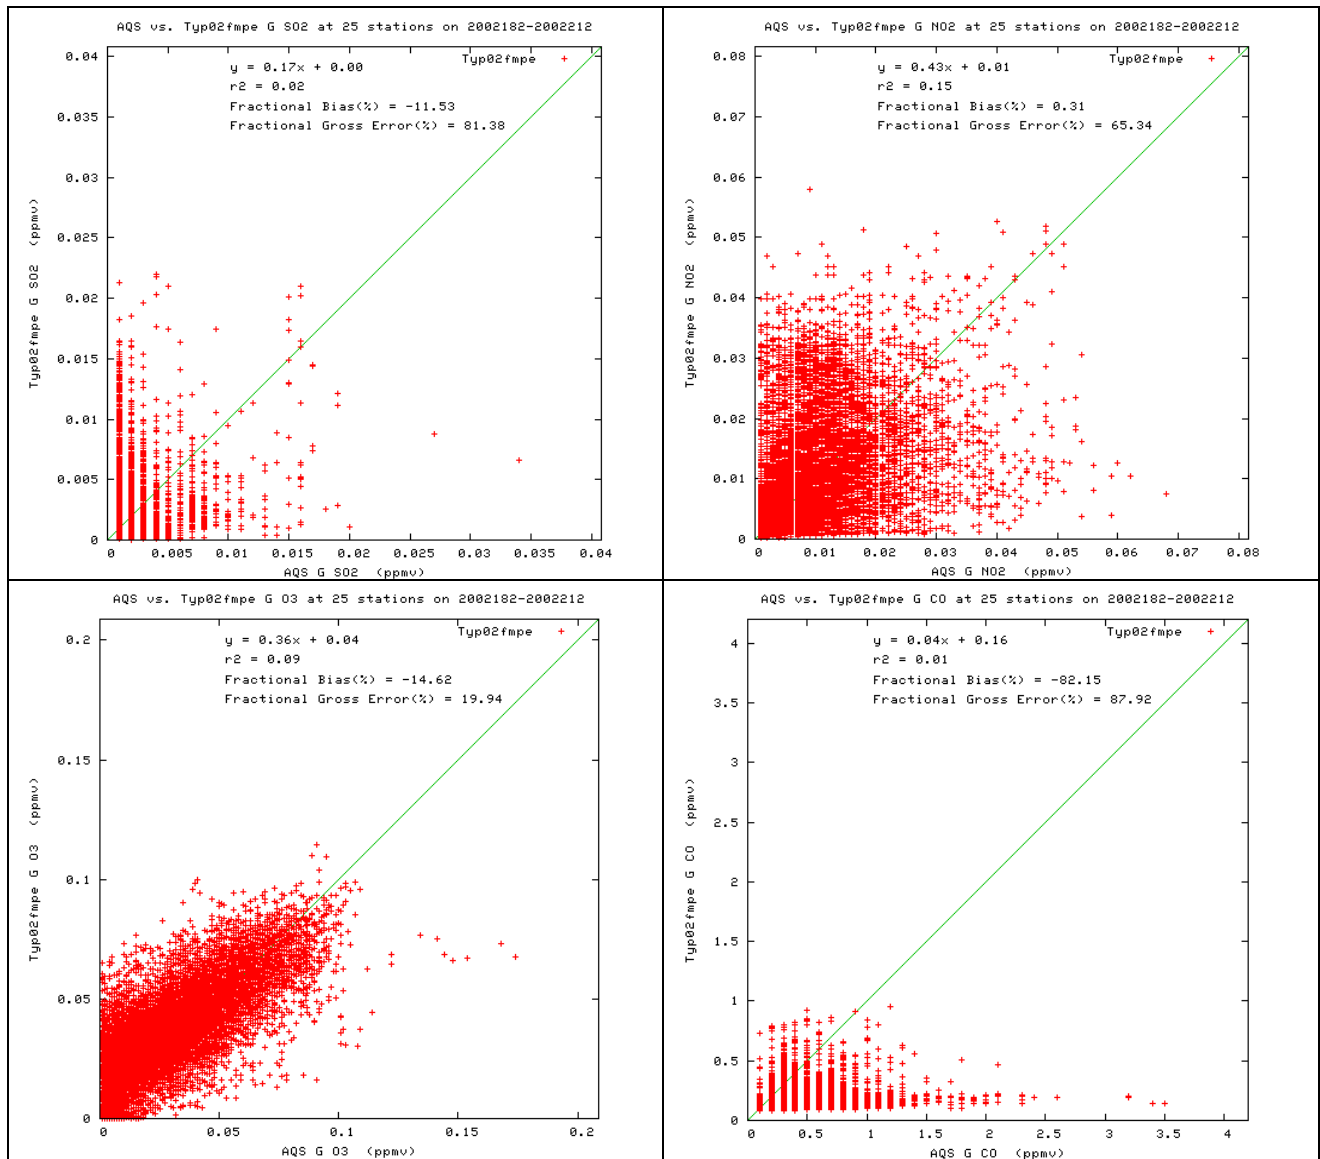

Figure C-45 July 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.4.4 Diagnostic Model Performance In October

SO₂ is overstated in October across the CASTNet (+28%) and AQS (+33%) sites (Figures C-46 and C-47). Although SO₄ is understated across the CASTNet sites (-24%), the bias across the IMPROVE (-6%) and STN (0%) sites are near zero (Figure C-7a).

Performance for HNO₃ is fairly good with a low bias (+12%) and error (30%). But NO₃ is overstated (+34%) leading to an overstatement of Total NO₃ (+37%). The overstatement of NO₃ leads to an overstatement of NH₄ as well (Figure C-46)

As seen in the other months, NO₂ exhibits a lot of scatter resulting in a low correlation (0.22) and high error (61%) but low bias (12%). The model tends to under-predict the high and over-predict the low O₃ observations resulting in a -29% bias and low correlation coefficient. CO is also under-predicted (-76%) for the reasons discussed previously.

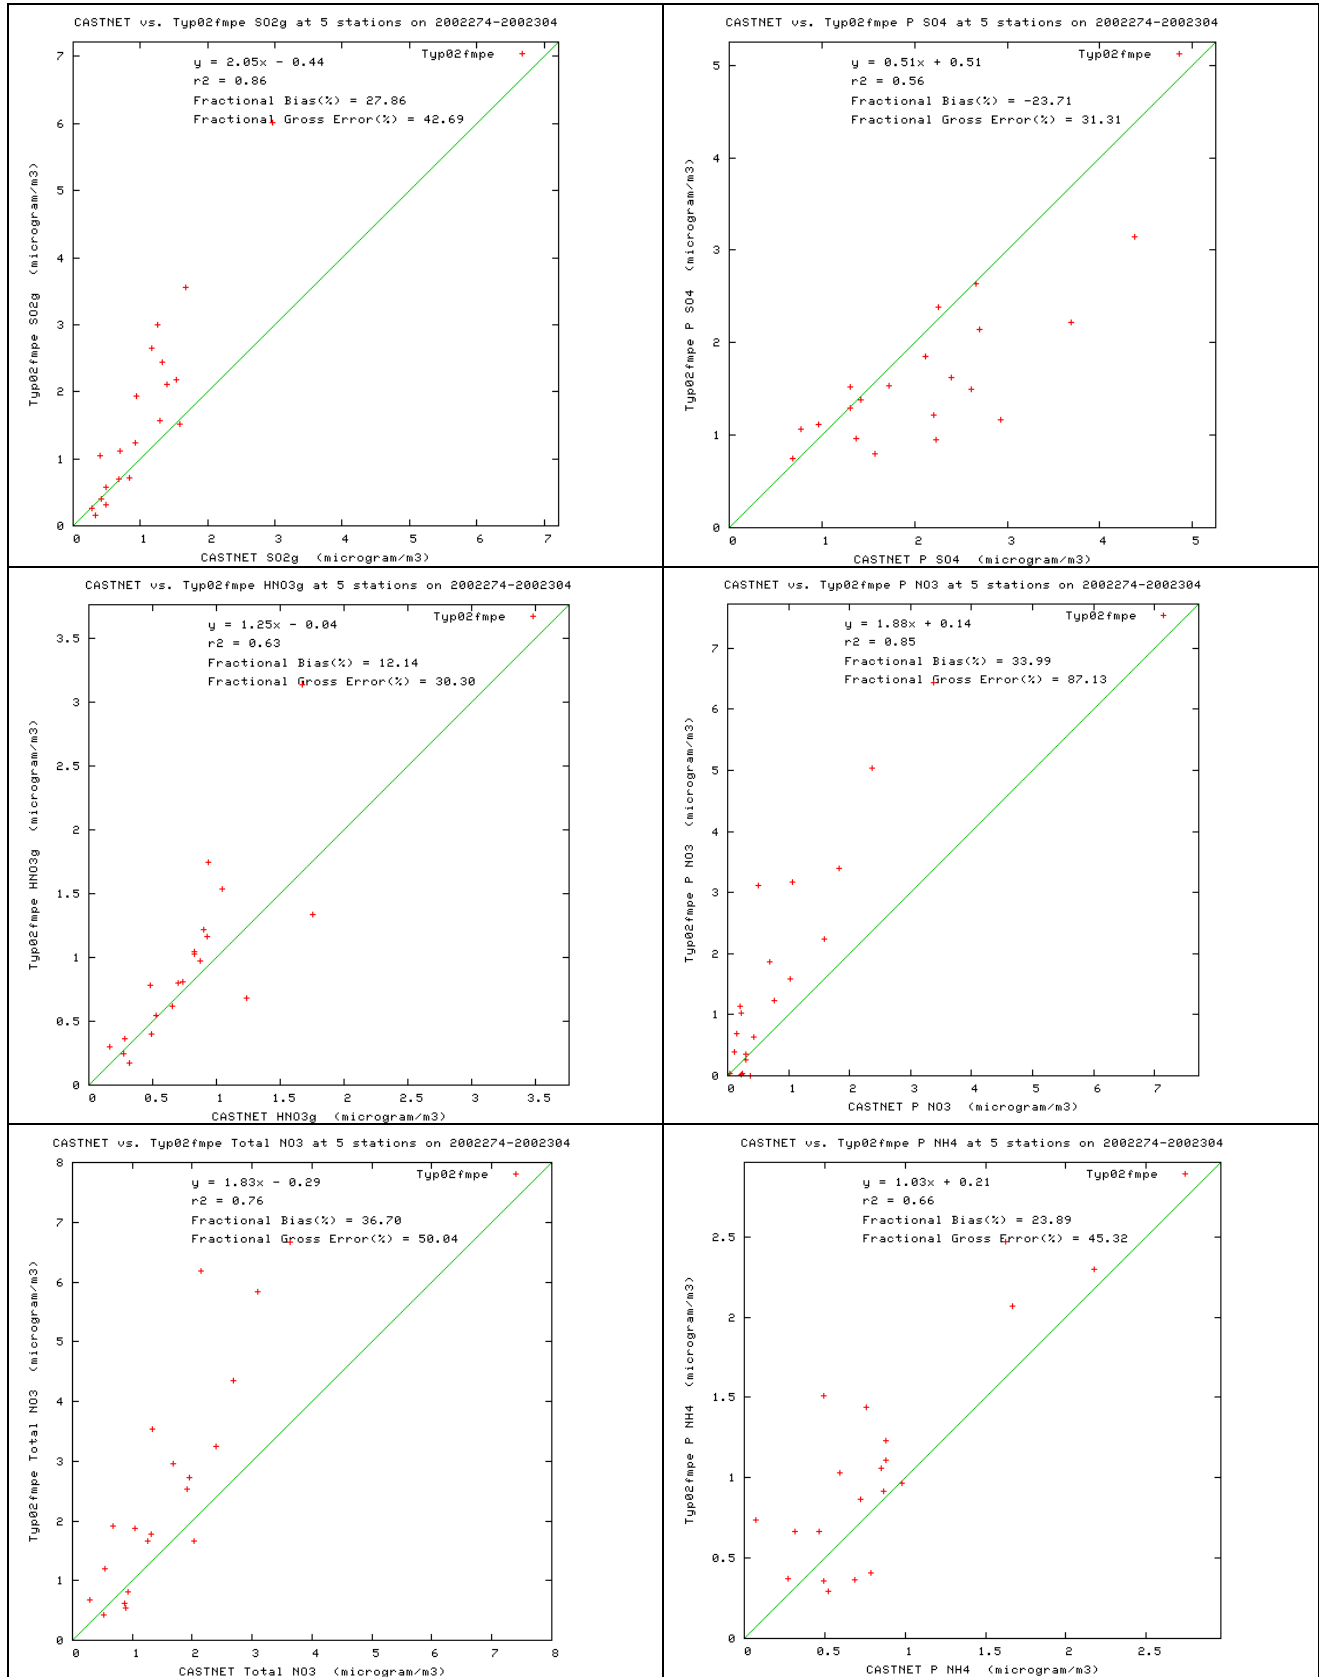

Figure C-46 October 2002 performance at CENRAP CASTNet sites for SO₂ (top left), SO₄ (top right), HNO₃ (middle left), NO₃ (middle right), Total NO₃ (bottom left) and NH₄ (bottom right).

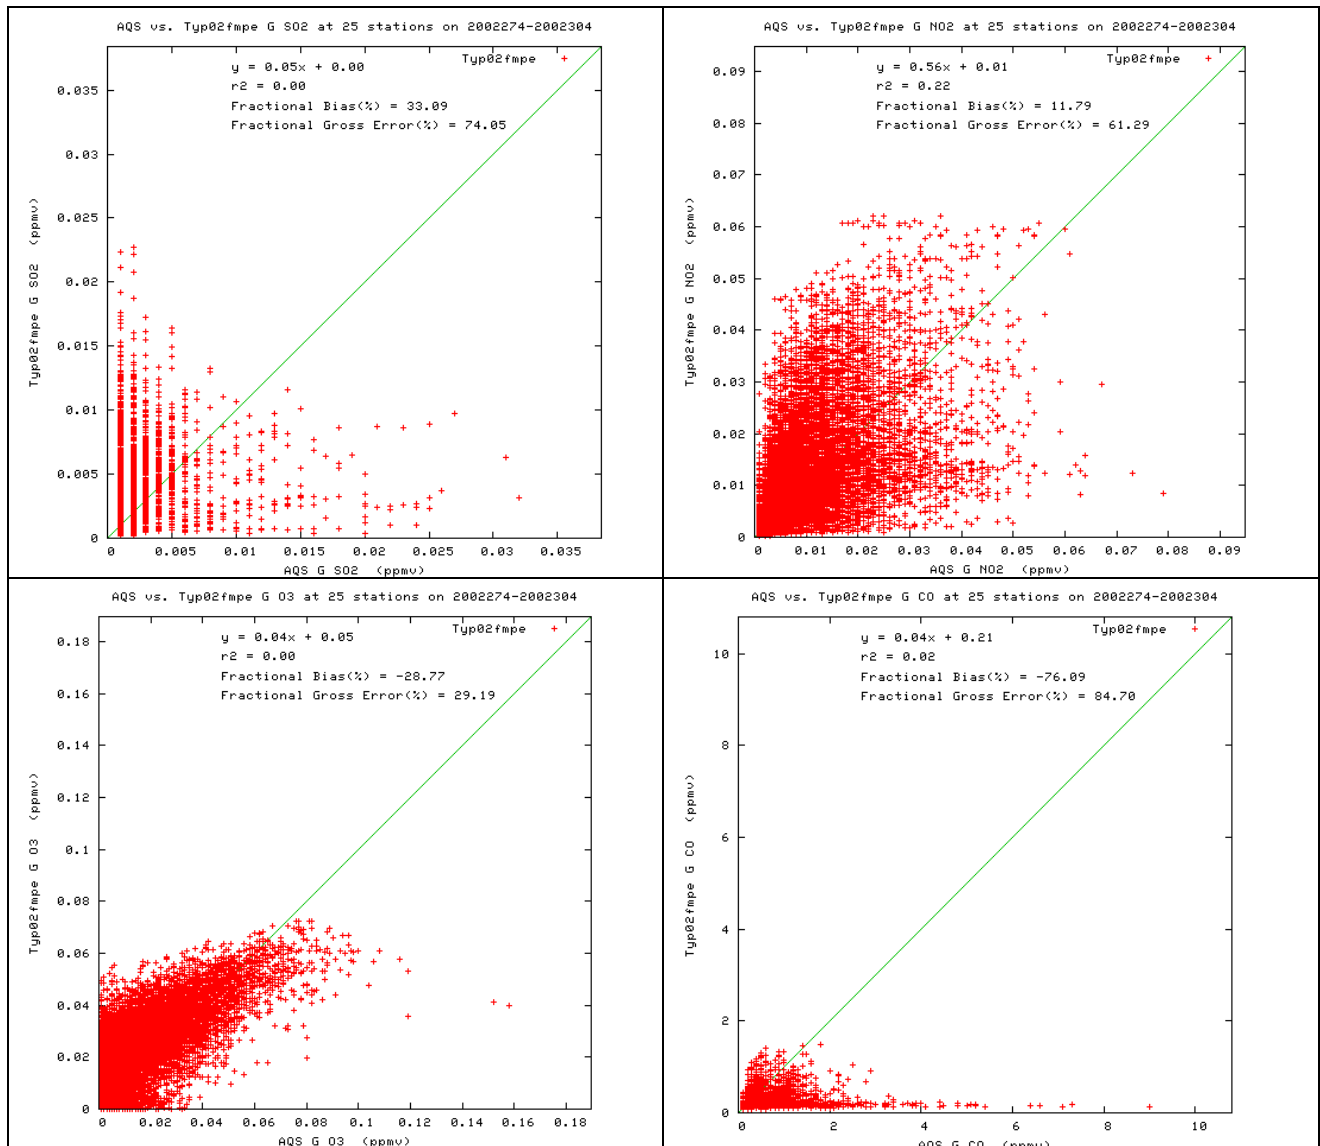

Figure C-47 October 2002 performance at CENRAP AQS sites for SO2 (top left), NO2 (top right), O3 (bottom left) and CO (bottom right).

C.5 Evaluation at Class I Areas for the Worst and Best 20 Percent Days

In this section, and in section C.5 of Appendix C, we present the results of the model performance evaluation at each of the CENRAP Class I areas for the worst and best 20 percent days. Performance on these days is critical since they are the days used in the 2018 visibility projections discussed in Chapter 4. For each Class I area we compared the predicted and observed total extinction (these figures are in Chapter 3) and PM species-specific extinction for the worst and best 20 percent days in 2002.

C.5.1 Caney Creek (CACR) Arkansas

The ability of the CMAQ model to estimate visibility extinction at the CACR Class I area on the 2002 worst and best 20 percent days is provide in Figures 3-9 and C-48. On most of the worst 20 percent days at CACR total extinction is dominated by SO₄ extinction with some extinction due to OMC. On four of the worst 20 percent days extinction is dominated by NO₃. The average extinction across the worst 20 percent days is underestimated by -33% (Figure 3-9), which is primarily due to a -51% underestimation of SO₄ extinction combined with a 6% overestimation of NO₃ extinction (Figure C-48). Performance for OMC extinction at CACR on the worst 20 percent days is pretty good with a -20% bias and 36% error, EC extinction is systematically underestimated, Soil extinction has low bias (-19%) but lots of scatter and high error (74%), while CM extinction is greatly underestimated (bias of -153%).

On the best 20 percent days at CACR the observed extinction ranges from 20 to 40 Mm⁻¹, whereas then modeled extinction has a much larger range from 15 to 120 Mm⁻¹. Much of the modeled overestimation of total extinction on the best 20% days (+44% bias) is due to NO₃ overestimation (+94% bias).

C.5.2 Upper Buffalo (UOBU) Arkansas

Model performance at the UPBU Class I area for the worst and best 20 percent days is shown in Figures 3-10 and C-49. On most of the worst 20 percent days at UPBU visibility impairment is dominated by SO₄, although there are also two high NO₃ days. The model underestimates the average of the total extinction on the worst 20 percent days at UPBU by -40% (Figure 3-10), which is due to an underestimation of extinction due to SO₄, OMC and CM by, respectively, -46%, -33% and -179%.

On the best 20 percent days at UPBU, the model performs reasonably well with a low bias (2%) and error (42%). But again the model has a much wider range in extinction values across the best 20 percent days (15 to 120 Mm⁻¹) than observed (20 to 45 Mm⁻¹). There are five days in which the modeled NO₃ over-prediction is quite severe and when those days are removed the range in the modeled and observed extinction on the best 20 percent days is quite similar, although the model gets much cleaner on the very cleanest modeled days.

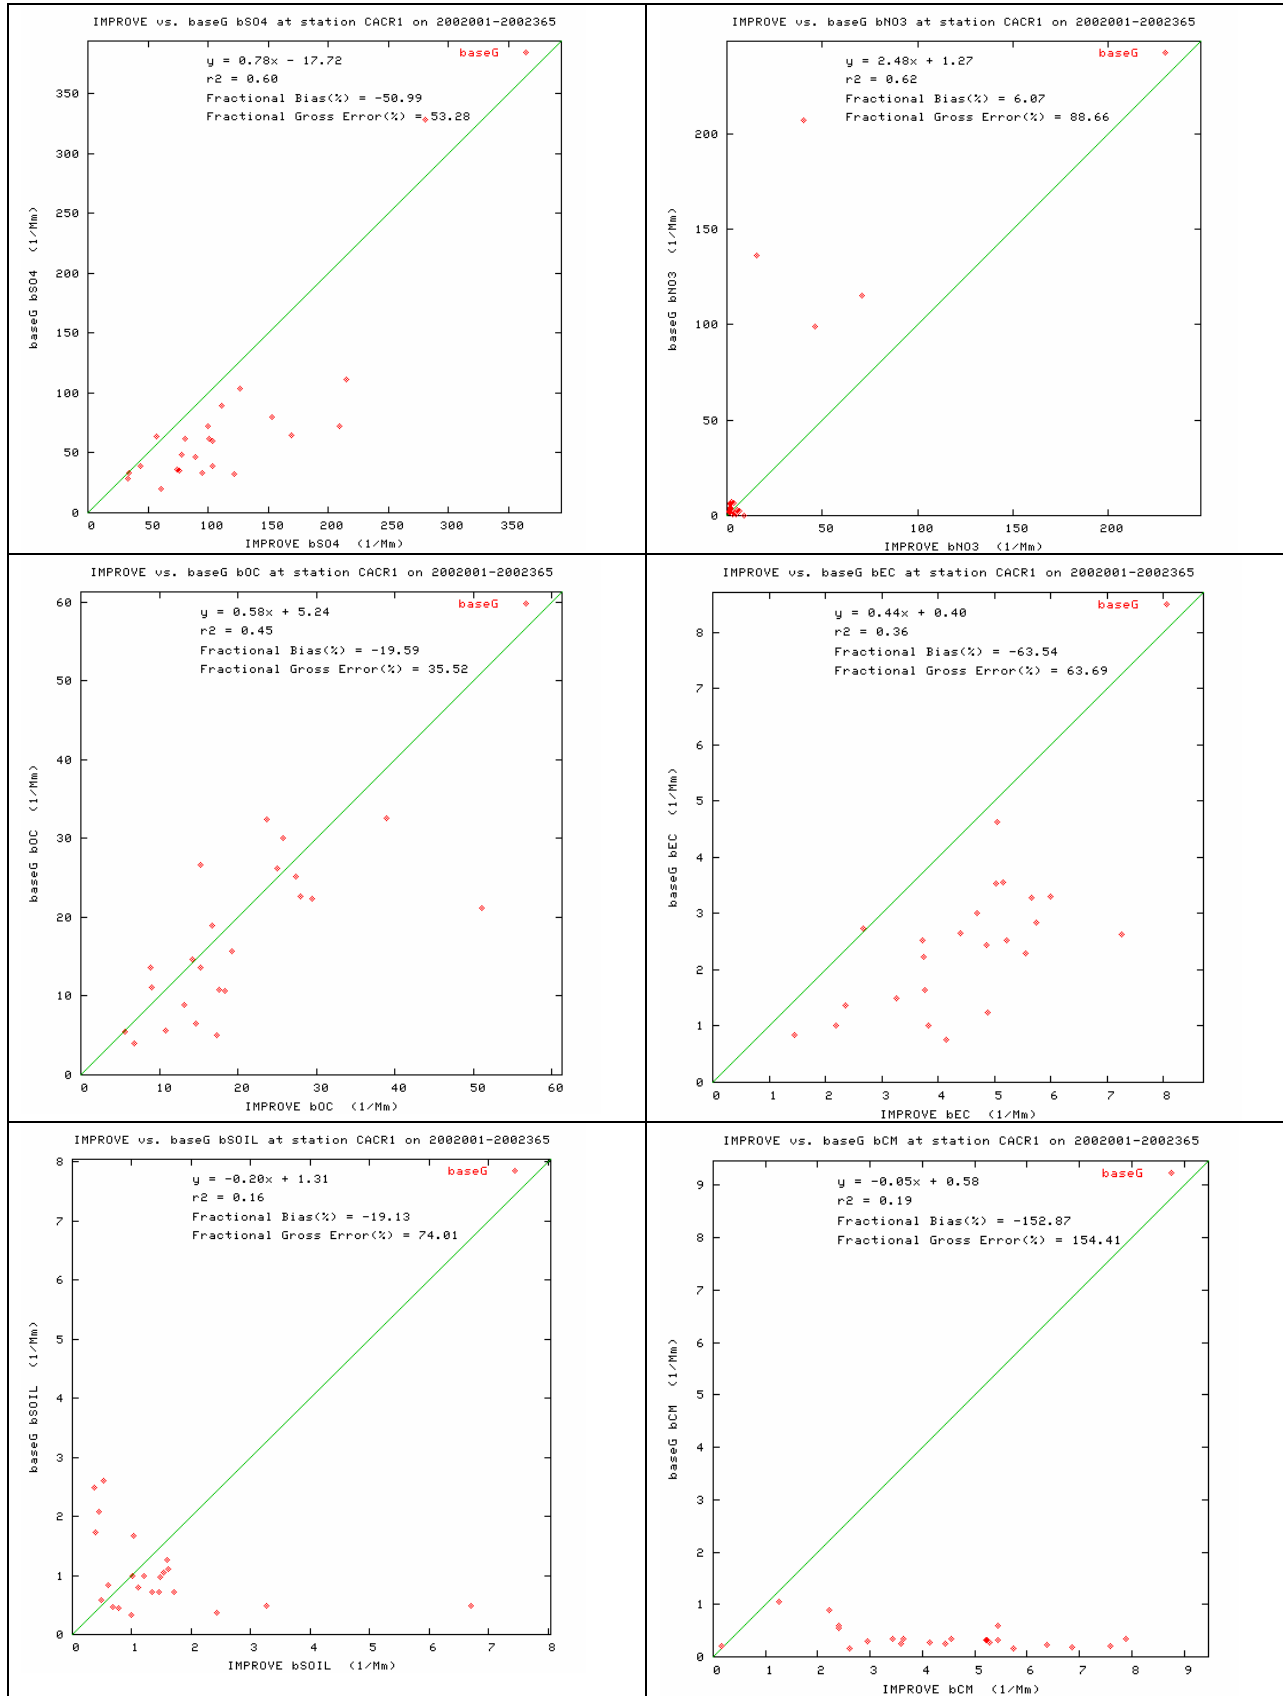

Figure C-48. PM species extinction model performance at Caney Creek (CACR) for the worst 20 percent days during 2002.

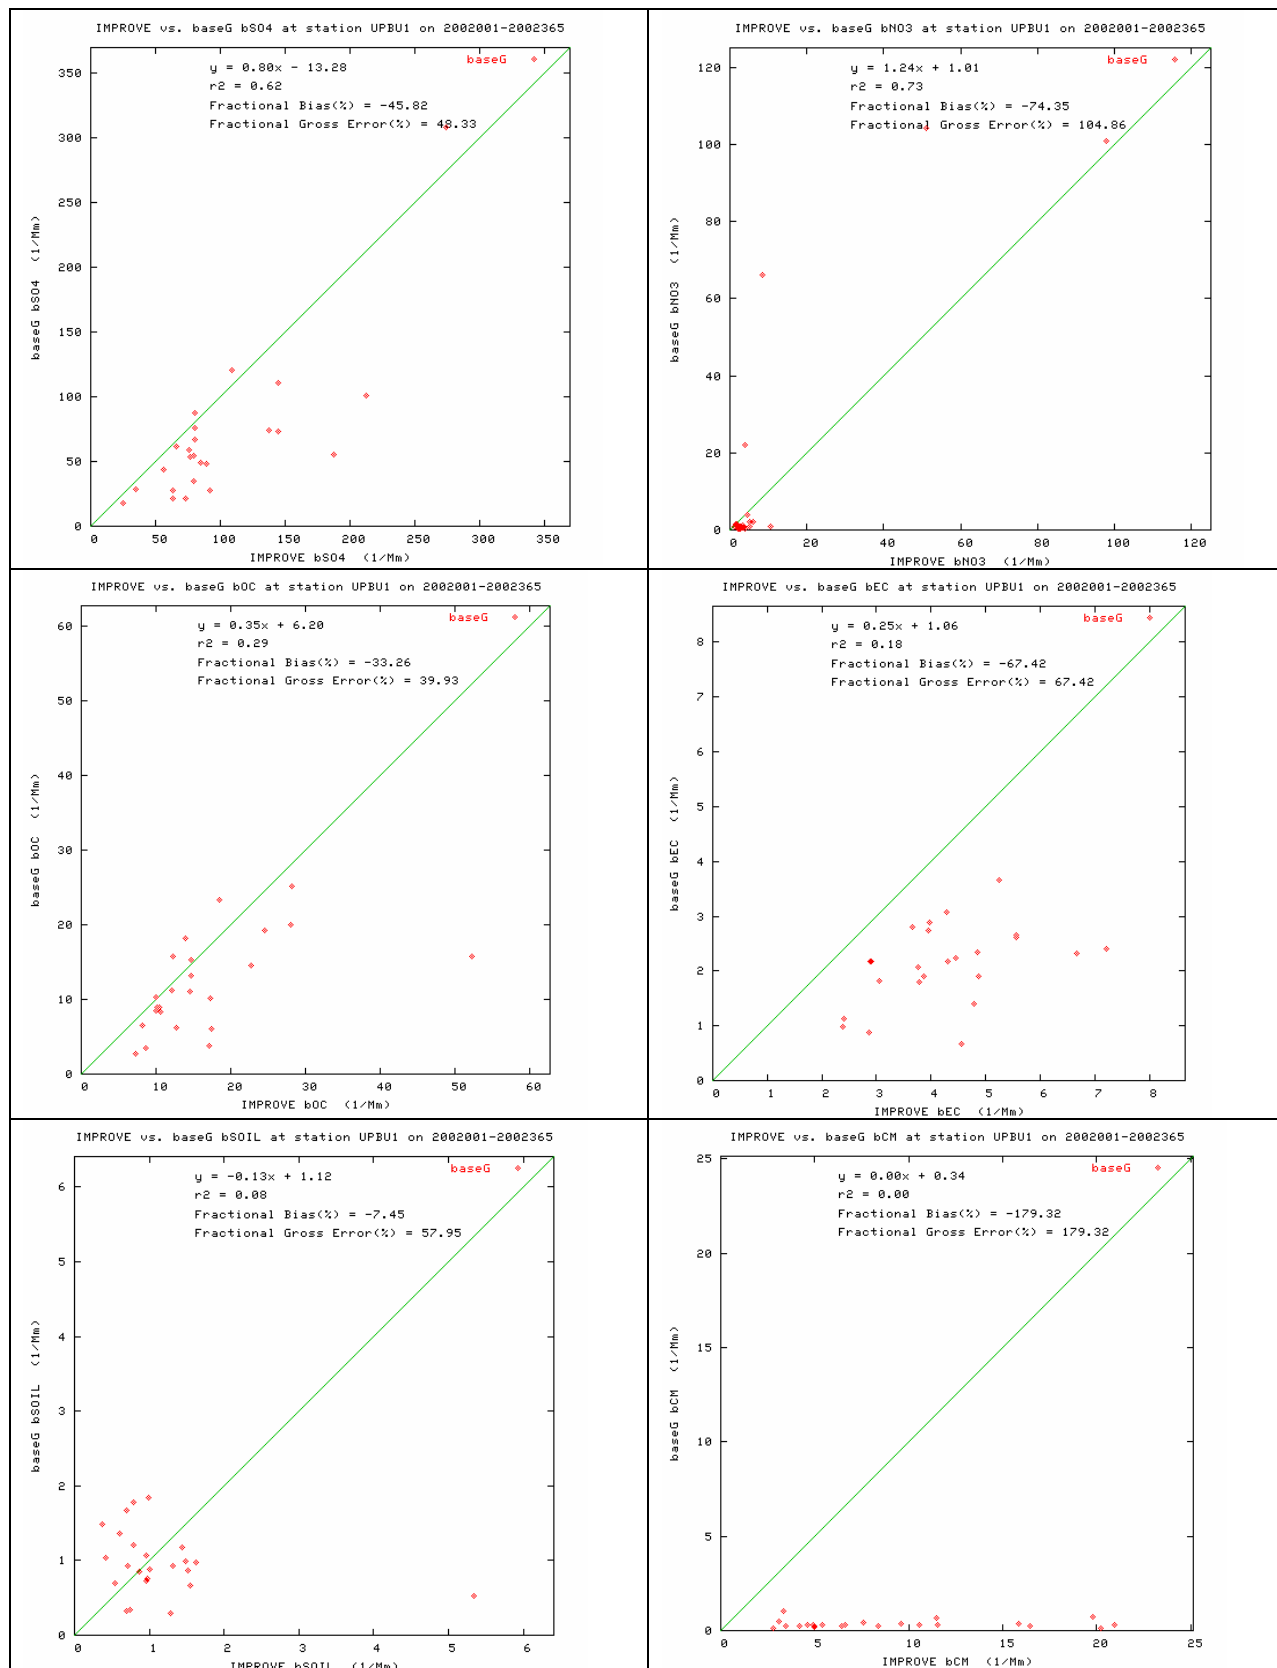

Figure C-49. PM species extinction model performance at Upper Buffalo (UPBU) for the worst 20 percent days during 2002.

C.5.3 Breton Island (BRET), Louisiana

The observed total extinction on the worst 20 percent days at Breton Island is underestimated by -71% (Figure 3-11), which is due to an underestimation of each component of extinction (Figure C-50) by from -50% to -70% (SO₄, OMC and Soil) to over -100% (EC and CM). The observed extinction on the worst 20 percent days ranges from 90 to 170 Mm⁻¹, whereas the modeled values drop down to as low as approximately 15 Mm⁻¹. On the best 20 percent days the range of the observed and modeled extinction is similarly (roughly 10 to 50 Mm⁻¹) that results in a reasonably low bias (-22%), but there is little agreement on which days are higher or lower resulting in a lot of scatter and high error (54%).

C.5.4 Boundary Waters (BOWA), Minnesota

There are three types of days during the worst 20 percent days at BOWA, SO₄ days, OMC days and NO₃ days (Figure 3-12). The two high OMC days are likely fire impact events that the model captures to some extent on one day and not on the other. On the five high (> 20 Mm⁻¹) NO₃ extinction days the model predicts the observed extinction well on three days and overestimates by a factor of 3-4 on the other two high NO₃ days. SO₄ in underestimate by -43% on average across the worst 20 percent days at BOWA.

With the exception of two days, the model reproduces the total extinction for the best 20 percent days at BOWA quite well with a bias and error value of +14% and 22% (Figure 3-12). Without these two days, the modeled and observed extinction both range between 15 and 25 Mm⁻¹.

C.5.5 Voyageurs (VOYA) Minnesota

VOYA is also characterized by SO₄, NO₃ and OMC days (Figure 3-13). Julian Days 179 and 200 are high OMC days that were also high OMC days at BOWA again indicating impacts from fires in the area that is not fully captured by the model. SO₄ and NO₃ extinction is fairly good and, without the fire days, OMC performance looks good as well (Figure C-52). On the best 20 percent days there is one day the modeled extinction is much higher than observed and a few others that are somewhat higher, but for most of the best 20 percent days the modeled extinction is comparable to the observed values.

Figure C-50. PM species extinction model performance at Breton Island (BRET) for the worst 20 percent days during 2002.

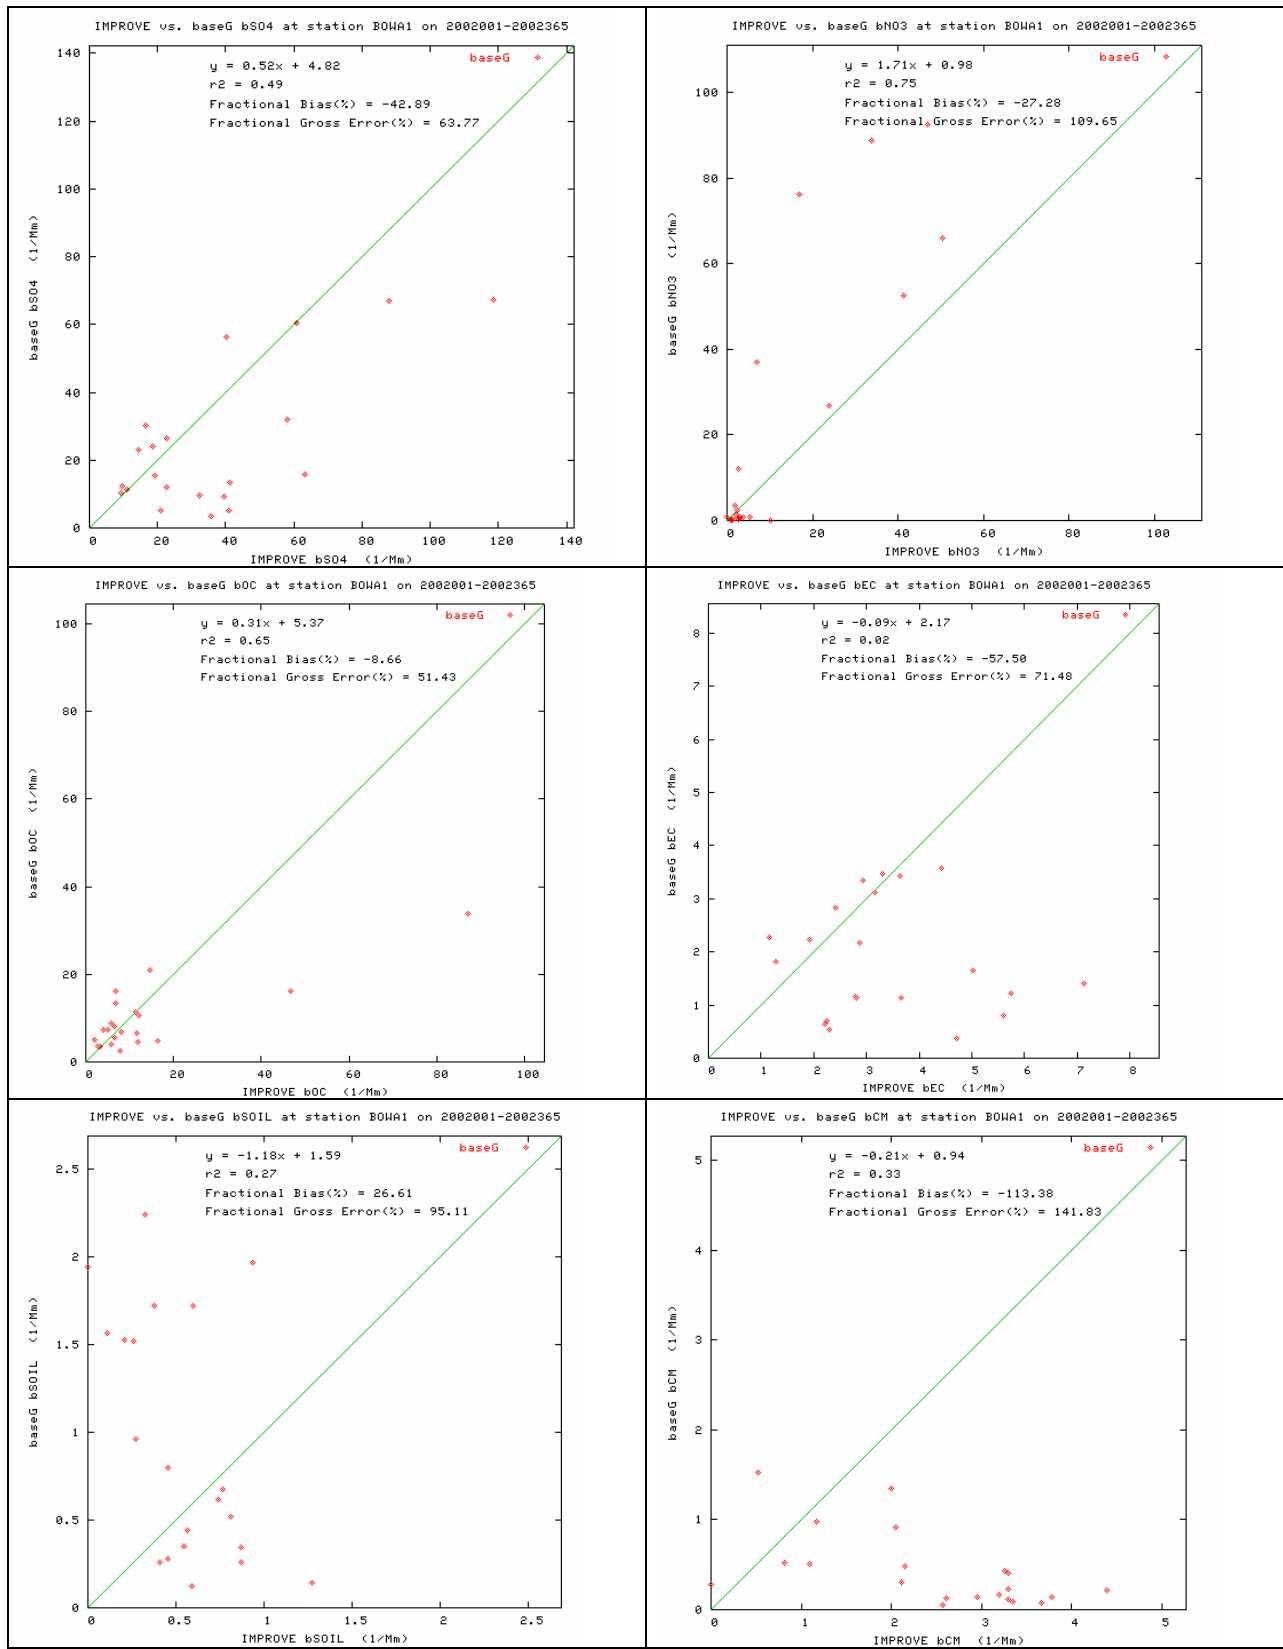

Figure C-51. PM species extinction model performance at Boundary Waters (BOWA) for the worst 20 percent days during 2002.

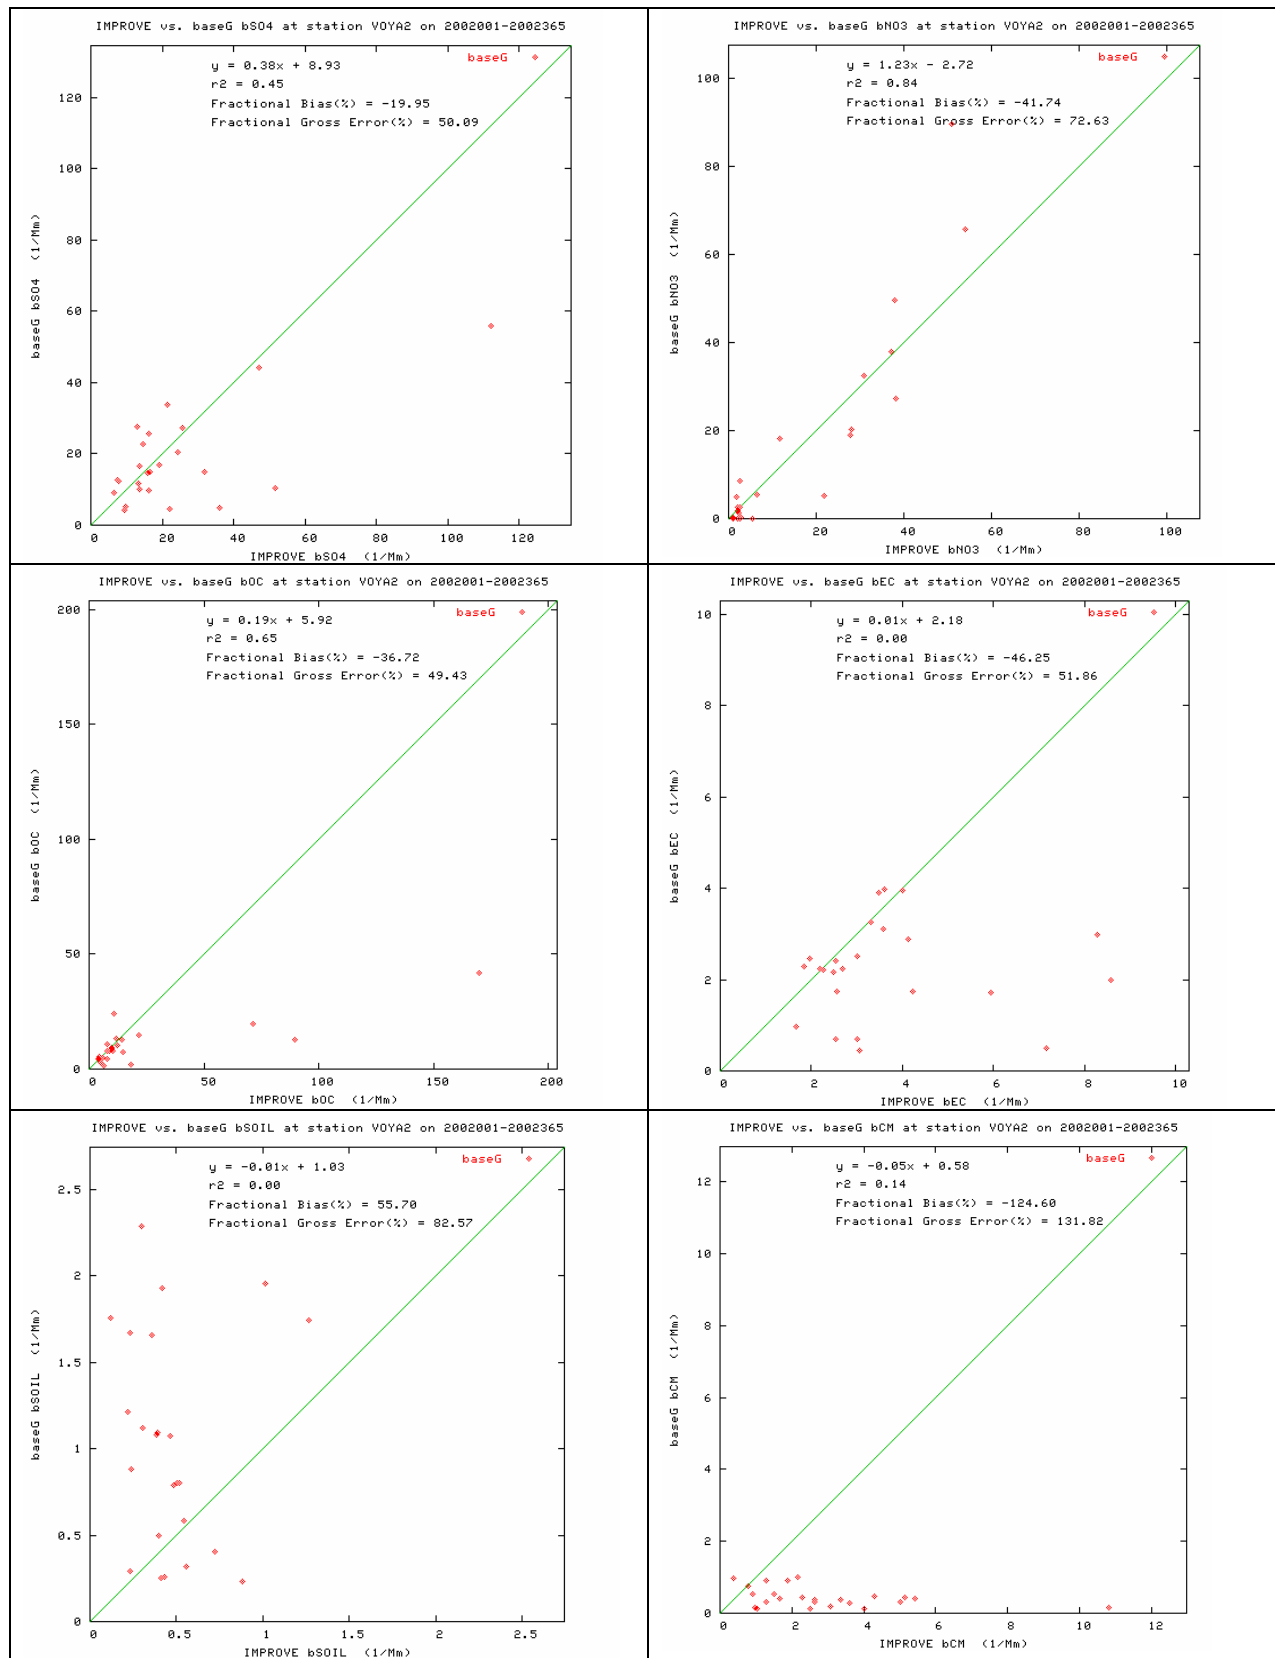

Figure C-52. PM species extinction model performance at Voyageurs (VOYA) for the worst 20 percent days during 2002.

C.5.6 Hercules Glade (HEGL) Missouri

On most of the worst 20 percent days at HEGL the observed extinction ranges from 120 to 220 Mm^{-1} whereas model extinction ranging from 50 to 170 Mm^{-1} (Figure 3-14). However, there is one extreme day with extinction approaching 400 Mm^{-1} that the model does a very good job in replicating. Over all the days there is a modest underestimation bias in SO_4 (-39%) and OMC (-39%) extinction, larger underestimation bias in EC (-62%) and CM (-118%) extinction and overestimation bias in Soil (+30%) extinction (Figure C-53).

On the best 20 percent days there is one day where the model overstates the observed extinction by approximately a factor of four and a handful of other days that the model overstates the extinction by a factor of 2 or so, but most of the days both the model and observed extinction sites are around 40 Mm^{-1} plus or minus about 10 Mm^{-1} . On the best 20 percent days when the observed extinction is overstated it is due to overstatement of the NO_3 .

C.5.7 Mingo (MING) Missouri

The worst 20 percent days at Ming are mainly high SO_4 days with a few high NO_3 days that the model reproduces reasonably well resulting in low bias (+10%) and error (38%) for total extinction (Figure 3-15). The PM species specific performance is fairly good with low bias for SO_4 (+4%), good agreement with NO_3 on high NO_3 days except for one day, low OMC (+23%) and EC (+3%) bias and larger bias in EC (+37%) and CM (-105%) extinction (Figure C-54).

For the best 20 percent days, there is one day the model is way too high due to overstated NO_3 extinction and a few other days the model overstates the observed extinction that is usually due to overrated NO_3 , but on most of the best 20 percent days the modeled extinction is comparable to the observed values. This results in low bias (+12%) and error (36%) for total extinction at MING for the best 20 percent days.

C.5.8 Wichita Mountains (WIMO), Oklahoma

With the exception of an over-prediction on day 344 due to NO_3 , observed total extinction on the worst 20 percent days at WIMO is understated with a bias of -42% (Figure 3-16) that is primarily due to an underestimation of extinction due to SO_4 (-48%) and OMC (-69%) (Figure C-55).

CMAQ total extinction performance for the average of the best 20 percent days at WIMO is characterized by an overestimation bias (+21%) on most days that is primarily due to NO_3 over-prediction on several days. Again the modeled range of extinction on the best 20 percent days (12-60 Mm^{-1}) is much greater than observed (20-35 Mm^{-1}).

Figure C-53. PM species extinction model performance at Hercules Glade (HEGL) for the worst 20 percent days during 2002.

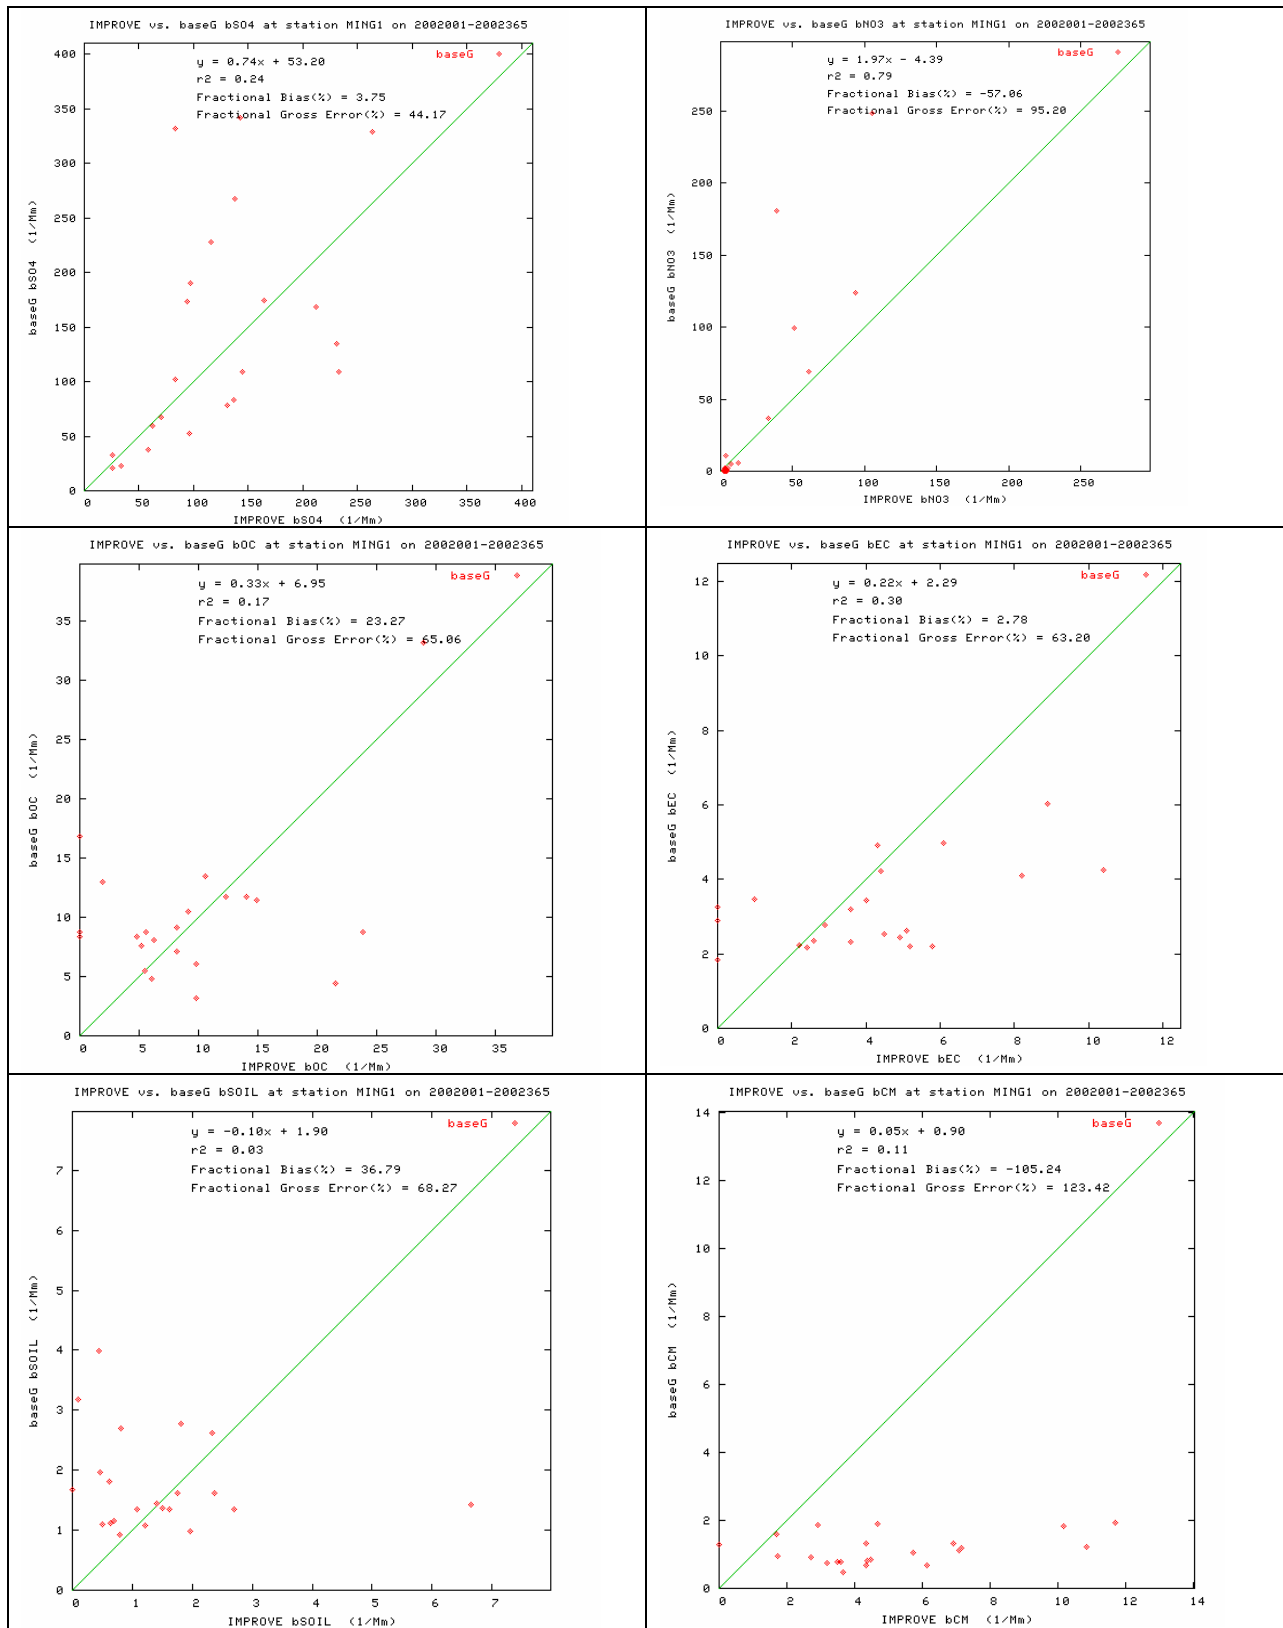

Figure C-54. PM species extinction model performance at Mingo (MING) for the worst 20 percent days during 2002.

Figure C-55. PM species extinction model performance at Wichita Mountains (WIMO) for the worst 20 percent days during 2002.

C.5.9 Big Bend (BIBE) Texas

The observed extinction on the worst 20 percent days at BIBE is under-predicted on almost every day resulting in a fractional bias value of -72% (Figure 3-17). Every component of extinction is underestimated on average for the worst 20 percent days (Figure C-56) with the underestimation bias ranging from -24% (OMC) to -162% (CM). SO₄ extinction, that typically represents the largest component of the total extinction is understated by -94%.

The model does a better job in predicting the total extinction at BIBE for the best 20 percent days with average fractional bias and error values of +13% and 19% (Figure 3-17). With the exception of one day that the observed extinction is overestimated by approximately a factor of 2, the modeled and observed extinction on the best 20 percent days at BIBE are both within 12 to 25 Mm⁻¹. However, there are some mismatches with the components of extinction with the model estimating much lower contributions due to Soil and CM.

C.5.10 Guadalupe Mountains (GUMO) Texas

Most of the worst 30 percent days at GUMO are dust days with high Soil and CM that is not at all captured by the model (Figure 3-18). Extinction due to Soil and CM on the worst 20 percent days is underestimated by -105% and -191%, respectively (Figure C-57). Better performance is seen on the best 20 percent days with bias and error for total extinction of 8% and 21%, but the model still understates Soil and CM.

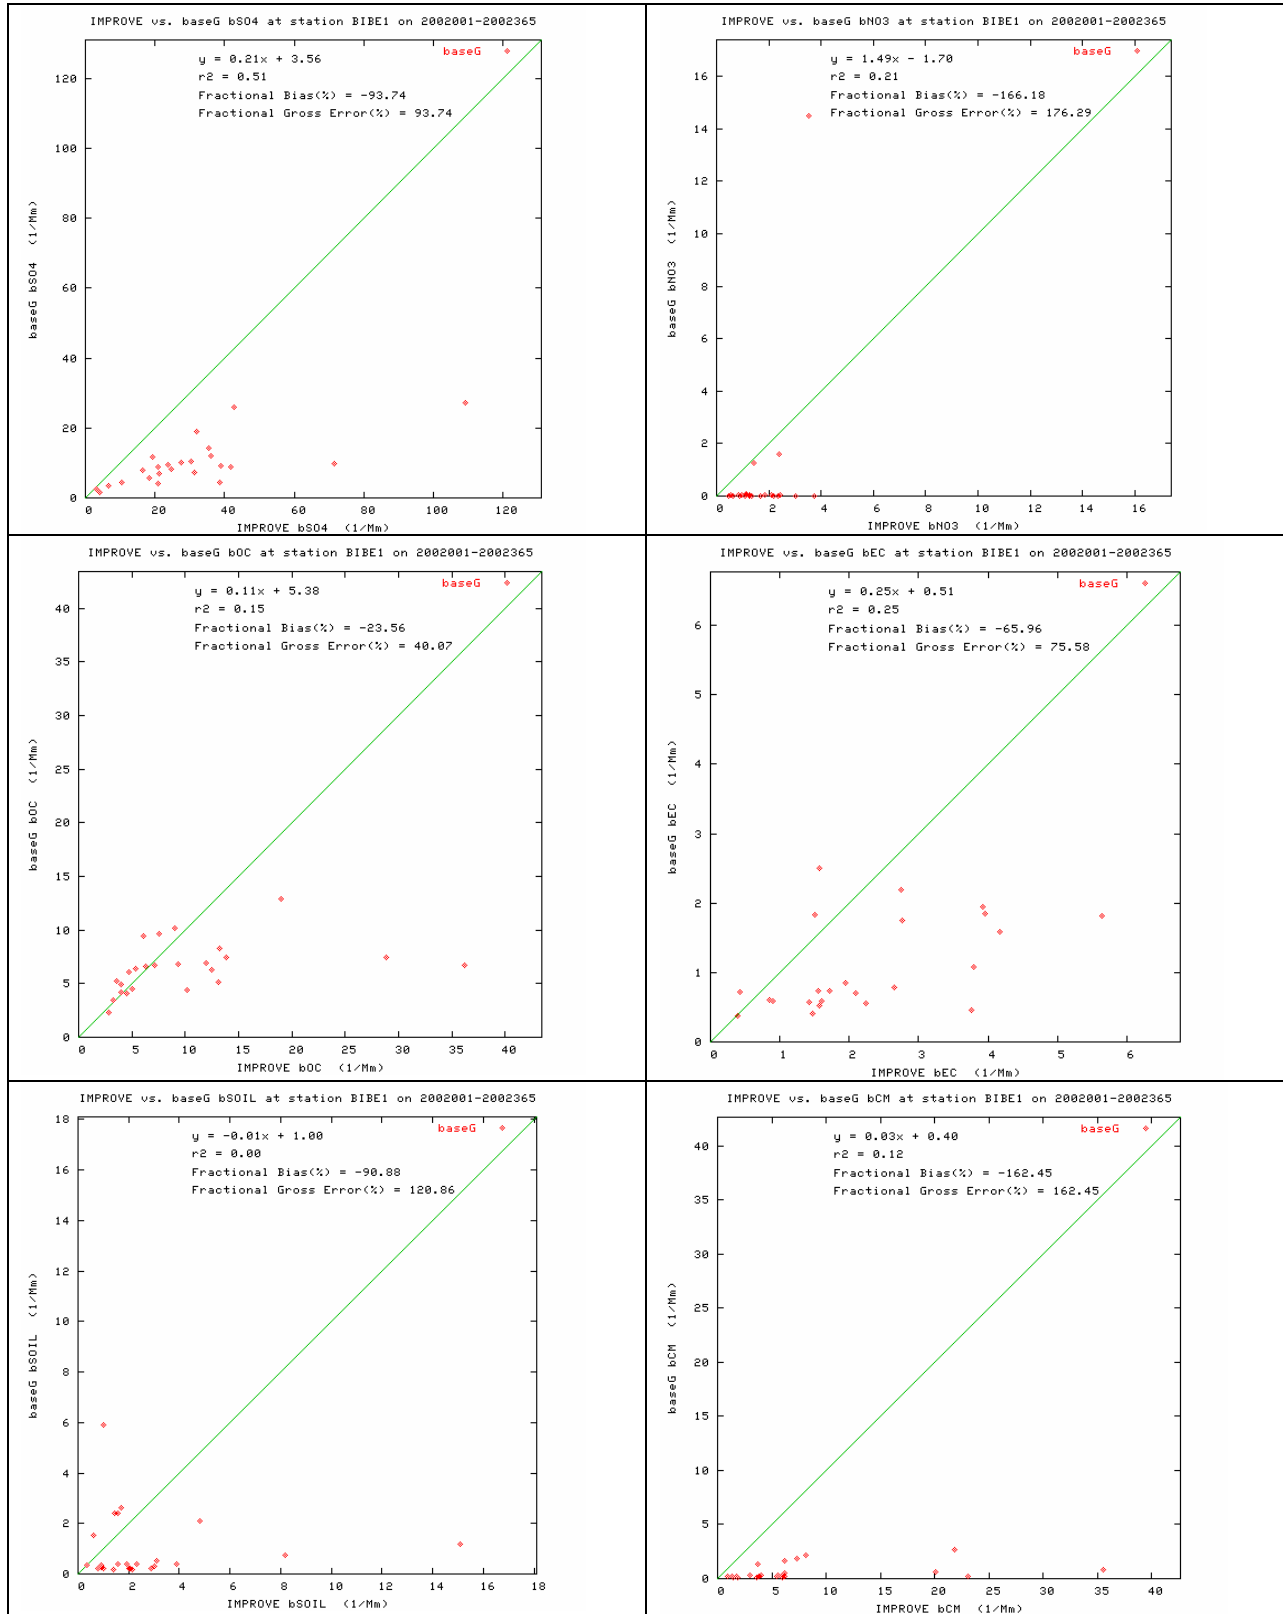

Figure C-56. PM species extinction model performance at Big Bend (BIBE) for the worst 20 percent days during 2002.

Figure C-57. PM species extinction model performance at Guadalupe Mountains (GUMO) for the worst 20 percent days during 2002.

C.6 Model Performance Evaluation Conclusions

The model performance evaluation reveals that the model is performing best for SO₄, OMC and EC. Soil performance is mixed with winter overestimation bias but lower bias but high error in the summer. CM performance is poor year round. The operational evaluation reveals that SO₄ performance usually achieves the PM model performance goal and always achieves the model performance criteria, although it does have an underestimation bias that is greatest in the summer. NO₃ performance is characterized by a winter overestimation bias with an even greater summer underestimation bias. However, the summer underestimation bias occurs when NO₃ is very low and it is not an important component of the observed or predicted PM and visibility impairment. Performance for OMC meets the model performance goal year round at the IMPROVE sites, but is characterized by an underestimation bias at the more urban STN sites. EC exhibits very low bias at the STN sites and a summer underestimation bias at the IMPROVE sites, but meets the model performance goal throughout the year. Soil has a winter overestimation bias that exceeds the model performance goal and criteria raising questions whether the model should be used for this species. Finally, CM performance is extremely poor with an under-prediction bias that exceeds the performance goal and criteria. We suspect that much of the CM concentrations measured at the IMPROVE sites is due to highly localized emissions that can not be simulated with 36 km regional modeling.

Performance for the worst 20 percent days at the CENRAP Class I areas is generally characterized by an underestimation bias. Performance at the BRET, BIBE and GUMO Class I areas for the worst 20 percent days is particularly suspect and care should be taken in the interpretation of the visibility projections at these three Class I areas.

The CMAQ 2002 36 km model appears to be working well enough to reliably make future-year projections for changes in SO₄, NO₃, EC and OMC at the rural Class I areas. Performance for Soil and especially CM is suspect enough that care should be taken in interpreting these modeling results. The model evaluation focused on the model's ability to predict the components of light extinction mainly at the Class I areas. Additional analysis would have to be undertaken to examine the model's ability to treat ozone and fine particulate to address 8-hour ozone and PM_{2.5} attainment issues.

Figure D-1a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - Best 20% Days

Figure D-1b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Caney Creek (CACR), Arkansas and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-1c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days in 2002.

Figure D-1d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure D-2a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - Best 20% Days

Figure D-2b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Upper Buffalo (UPBU), Arkansas and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-2c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days in 2002.

Figure D-2d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure D-3a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - Best 20% Days

Figure D-3b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Breton Island (BRET), Louisiana and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-3c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Breton Island (BRET), Louisiana and Worst 20% (W20%) days in 2002.

Figure D-3d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Breton Island (BRET), Louisiana and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure D-4a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - Best 20% Days

Figure D-4b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Boundary Waters (BOWA), Minnesota and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Worst 20% Obs (left) vs Typ02g (right) at BOWA1

Figure D-4c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days in 2002.

Bext Response (base18g - typ02g) at BOWA1 on Worst 20% Days

Figure D-4d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Voyageurs NP - 20% Data Days

Figure D-5a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Voyageurs (VOYA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Voyageurs NP - Best 20% Days

Figure D-5b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Voyageurs (VOYA), Minnesota and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-5c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Voyagers (VOYA), Minnesota and Worst 20% (W20%) days in 2002.

Figure D-5d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Voyagers (VOYA), Minnesota and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Hercules-Glades Wilderness - 20% Data Days

Figure D-6a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Hercules-Glade (HEGL), Missouri and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Hercules-Glades Wilderness - Best 20% Days

Figure D-6b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Hercules-Glade (HEGL), Missouri and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-6c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Hercules-Glade (HEGL), Missouri and Worst 20% (W20%) days in 2002.

Figure D-6d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Hercules-Glade (HEGL), Missouri and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Mingo - 20% Data Days

Figure D-7a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Mingo (MING), Missouri and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Mingo - Best 20% Days

Figure D-7b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Mingo (MING), Missouri and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-7c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Mingo (MING), Missouri and Worst 20% (W20%) days in 2002.

Figure D-7d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Mingo (MING), Missouri and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Wichita Mountains - 20% Data Days

Figure D-8a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Wichita Mountains (WIMO), Oklahoma and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Wichita Mountains - Best 20% Days

Figure D-8b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Wichita Mountains (WIMO), Oklahoma and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-8c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Wichita Mountains (WIMO), Oklahoma and Worst 20% (W20%) days in 2002.

Figure D-8d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Wichita Mountains (WIMO), Oklahoma and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Big Bend NP - 20% Data Days

Figure D-9a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Big Bend (BIBE), Texas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Big Bend NP - Best 20% Days

Figure D-9b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Big Bend (BIBE), Texas and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-9c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Big Bend (BIBE), Texas and Worst 20% (W20%) days in 2002.

Figure D-9d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Big Bend (BIBE), Texas and Worst 20% (W20%) days in 2002.

Uniform Rate of Reasonable Progress Glide Path Guadalupe Mountains NP - 20% Data Days

Figure D-10a. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Guadalupe Mountains (GUMO), Texas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Guadalupe Mountains NP - Best 20% Days

Figure D-10b. 2018 Visibility Projections and 2018 URP Glidepaths in deciview for Guadalupe Mountains (GUMO), Texas and Best 20% (B20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Figure D-10c. Comparison of observed (left) and 2002 Base G modeled (right) daily extinction for Guadalupe Mountains (GUMO), Texas and Worst 20% (W20%) days in 2002.

Figure D-10d. Differences in modeled 2002 and 2018 Base G CMAQ results (2018-2002) daily extinction for Guadalupe Mountains (GUMO), Texas and Worst 20% (W20%) days in 2002.

APPENDIX E

CAMx PM Source Apportionment Technology (PSAT) Extinction (Mm^{-1}) Contributions for the 2002 Worst and Best 20 Percent Days at CENRAP Class I Areas

- Figure F-7: Mingo Wilderness Area (MING), Missouri
- Figure F-8: Wichita Mountains Wilderness Area (WIMO), Oklahoma
- Figure F-9: Big Bend National Park (BIBE), Texas
- Figure F-10: Guadalupe Mountains National Park (GUAD), Texas

**Uniform Rate of Reasonable Progress Glide Path
Caney Creek Wilderness - 20% Data Days**

Figure F-1a. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

**Uniform Rate of Reasonable Progress Glide Path
Caney Creek Wilderness - 20% Data Days**

Figure F-1b. 2018 Visibility Projections and 2018 URP Glidepaths for Sulfate (SO_4) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - 20% Data Days

Figure F-1c. 2018 Visibility Projections and 2018 URP Glidepaths for Nitrate (NO_3) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - 20% Data Days

Figure F-1d. 2018 Visibility Projections and 2018 URP Glidepaths for Elemental Carbon (EC) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - 20% Data Days

Figure F-1e. 2018 Visibility Projections and 2018 URP Glidepaths for Organic Mass Carbon (OMC) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - 20% Data Days

Figure F-1f. 2018 Visibility Projections and 2018 URP Glidepaths for Other Fine Particulate (SOIL) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Caney Creek Wilderness - 20% Data Days

Figure F-1g. 2018 Visibility Projections and 2018 URP Glidepaths for Coarse Mass (CM) in extinction (Mm^{-1}) for Caney Creek (CACR), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2a. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2b. 2018 Visibility Projections and 2018 URP Glidepaths for Sulfate (SO_4) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2c. 2018 Visibility Projections and 2018 URP Glidepaths for Nitrate (NO_3) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2d. 2018 Visibility Projections and 2018 URP Glidepaths for Elemental Carbon (EC) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2e. 2018 Visibility Projections and 2018 URP Glidepaths for Organic Mass Carbon (OMC) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2f. 2018 Visibility Projections and 2018 URP Glidepaths for Other Fine Particulate (SOIL) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Upper Buffalo Wilderness - 20% Data Days

Figure F-2g. 2018 Visibility Projections and 2018 URP Glidepaths for Coarse Mass (CM) in extinction (Mm^{-1}) for Upper Buffalo (UPBU), Arkansas and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3a. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3b. 2018 Visibility Projections and 2018 URP Glidepaths for Sulfate (SO_4) in extinction (Mm^{-1}) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3c. 2018 Visibility Projections and 2018 URP Glidepaths for Nitrate (NO₃) in extinction (Mm⁻¹) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3d. 2018 Visibility Projections and 2018 URP Glidepaths for Elemental Carbon (EC) in extinction (Mm⁻¹) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3e. 2018 Visibility Projections and 2018 URP Glidepaths for Organic Mass Carbon (OMC) in extinction (Mm^{-1}) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3f. 2018 Visibility Projections and 2018 URP Glidepaths for Other Fine Particulate (SOIL) in extinction (Mm^{-1}) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Breton - 20% Data Days

Figure F-3g. 2018 Visibility Projections and 2018 URP Glidepaths for Coarse Mass (CM) in extinction (Mm^{-1}) for Breton Island (BRET), Louisiana and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4a. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4b. 2018 Visibility Projections and 2018 URP Glidepaths for Sulfate (SO_4) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4c. 2018 Visibility Projections and 2018 URP Glidepaths for Nitrate (NO_3) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4d. 2018 Visibility Projections and 2018 URP Glidepaths for Elemental Carbon (EC) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4e. 2018 Visibility Projections and 2018 URP Glidepaths for Organic Mass Carbon (OMC) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4f. 2018 Visibility Projections and 2018 URP Glidepaths for Other Fine Particulate (SOIL) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Boundary Waters Canoe Area - 20% Data Days

Figure F-4g. 2018 Visibility Projections and 2018 URP Glidepaths for Coarse Mass (CM) in extinction (Mm^{-1}) for Boundary Waters (BOWA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Voyagers NP - 20% Data Days

Figure F-5a. 2018 Visibility Projections and 2018 URP Glidepaths in extinction (Mm^{-1}) for Voyageurs (VOYA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Uniform Rate of Reasonable Progress Glide Path Voyagers NP - 20% Data Days

Figure F-5b. 2018 Visibility Projections and 2018 URP Glidepaths for Sulfate (SO_4) in extinction (Mm^{-1}) for Voyageurs (VOYA), Minnesota and Worst 20% (W20%) days using 2002/2018 Base G CMAQ 36 km modeling results.

Alpine Geophysics
Final Report...

VIA E-MAIL

9 May 2006

Mr. Jeff Peltola
CENRAP Technical Director
10005 S. Pennsylvania, Ste C
Oklahoma City, OK 73159

Dear Jeff:

The scientists at Alpine Geophysics are pleased to submit the attached document titled "Final CENRAP Regional Haze Control Strategy Analysis Plan" as outlined in Task 6 of our previously submitted quotation and work plan.

This document and associated materials are the product of our development and application of a quantitative procedure to identify and prioritize potential regional haze control strategies for Class I areas failing to meet visibility goal objectives. Additionally, we have addressed as many of the comments on the draft control strategy analysis plan as submitted to Alpine (April 25 and later) as we have determined to be within the scope of our original proposal to CENRAP.

To facilitate subsequent use of this methodology by CENRAP or others, this Final Report describes the various analytical steps and provides examples of this procedure (both in the body of the report and in supporting in appendixes). Document appendices and relevant technical support information have archived on the Alpine Geophysics project website facilitating easy access by interested parties. The login and password to access these data is provided below.

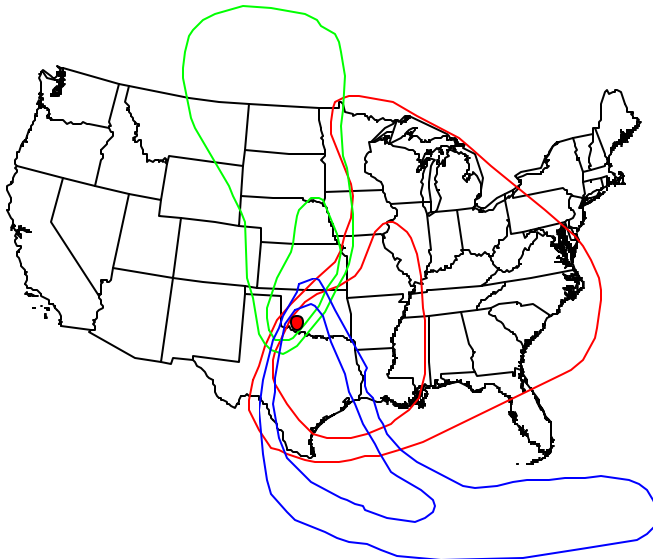

```

EXECUTIVE SUMMARY

The Implementation and Control Strategies (ICS) Workgroup of the Central Regional Air Planning Association (CENRAP), together with other workgroups and state, tribal and federal agencies, have been working for more than four years gathering information for developing regional haze (RH) control strategies for pertinent Class I areas within and adjacent to the CENRAP states and tribes. In late February 2006, under the direction of the CENRAP Technical Director, Alpine Geophysics, LLC was contracted to assist the ICS in this effort. Building upon information developed by the ICS and others, Alpine was charged with developing a quantitative procedure to identify and prioritize potential RH control strategies to be tested by CENRAP modelers. Alpine formulated a methodology for constructing control strategy recommendations based on presently available information and submitted a Work Plan detailing this approach to the ICS/CENRAP leadership for review and approval.

Using the results of preliminary and more recent CENRAP visibility projection modeling together with current information on the composition of visibility-impairing fine particulate aerosols at 22 Class I monitors, Alpine identified residual visibility progress 'increments' that potentially require additional regional and/or subregional emission reductions to achieve visibility goals¹. We synthesized pertinent 'attribution of haze' documents, CENRAP CAMx/CMAQ visibility modeling results, our own fine particulate modeling in the central U.S, and other technical reports, papers, and analyses bearing directly on the quantification of emissions-source/visibility-receptor impacts at the ten CENRAP Class I and twelve adjoining areas.

Complementing this task, we synthesized a number of recent regional modeling studies helpful in relating emissions reductions of visibility precursors (e.g. SO₂, NO_x) in upwind source regions (Areas of Influence or AOIs) to the improvement in visibility (in deciviews or Mm⁻¹) at downwind Class I areas. Figures ES-1 and ES-2 present 'level 1' AOI plots for sulfate and nitrate impacts at the Big Bend, Guadalupe, Wichita Mountains, Breton Island, Voyageurs, and Boundary Waters Class I Areas, respectively. Three distinct levels of AOI have been estimated for each visibility precursor and Class I areas, but the controls most likely to be considered for modeling will be drawn from the closest (i.e., AOI level 1 or AOI-1) area of influence for each Class I area/visibility precursor pair.

¹ We use the term 'increment' to denote the difference between the modeled visibility at a Class I area in 2018 compared to the value based on the Reasonable Progress Goal (RPG) glide path, evaluated at the same time period. A positive increment means that the modeled visibility at the Class I area is 'poorer' than the level associated with the linear RPG glide path. Accordingly, CENRAP may wish to consider recommending additional precursor controls to ameliorate such a positive visibility increment. In contrast, a negative increment suggests that the modeled growth and emissions controls by 2018 may produce better visibility conditions at the monitor when compared to the linear glide path.

We then deduced from available regional modeling studies 'rules of thumb' relating percentage or tonnage reductions in visibility reducing precursors (e.g., SO₂, NO_x, ammonia, and VOCs) on the expected impact on visibility downwind. These 'rules of thumb', i.e., source-receptor relationships, were essential in estimating the amounts of incremental precursor emissions reductions in regions upwind of each of the various Class I areas that CENRAP modelers should consider in the prescription of initial RH control strategy simulations.

Once an emissions reduction target was determined for each Class I area showing visibility projections above the uniform rate of progress line (i.e., a positive visibility increment), we applied a master list of controls on sources within the Class I AOIs to formulate the CENRAP Control Strategy plan, including cost-effectiveness as a key element.

Alpine's analysis of the most recent CENRAP visibility projection data identified six Class I areas within the CENRAP domain whose projected visibility falls above the uniform rate of progress line (i.e., a projected positive visibility increment). On this basis, we quantified their associated AOIs, emission reduction estimates for reaching 2018 reasonable progress objectives, and potential incremental emission reductions worthy of annual CMAQ/CAMx modeling. For each area, sulfate and to a lesser extent, nitrate reductions were shown to be most beneficial during the 20 percent worst visibility days in 2002.

As each of these areas (and all of the other Class I AOIs in the CENRAP domain) are dominated by EGU SO₂ and NO_x emissions and many of the Class I area AOIs intersect with States currently excluded by the EPA CAIR rule, a region-wide strategy for additional EGU emission reductions at CAIR levels for the non-CAIR EGUs may be beneficial to each Class I area in the CENRAP domain projected below the uniform rate of progress line. An alternate intra-state trading permutation of this regional approach is also recommended for review by CENRAP.

In lieu of a single regional control option applied consistently across the entire CENRAP domain, individual subregional control applications are proposed to reduce emissions within certain Class I area AOIs. Based on the single precursor emission reduction target calculations defined by the ICS, subregional control strategies can be defined for three of the Class I areas projected to be above the reasonable progress glide path². In each case, the marginal cost curves (based on the application of all available control options on all controllable industries and source types) allow the selection of control technologies which attains the ICS defined, AOI-1 specific emission reduction targets.

However, the application of incremental control on all controllable point and area sources within certain AOIs still fails to meet the visibility objectives of three Class I areas modeled to be above the reasonable progress glide slope. In fact, as a result of the implementation of the exhaustive list of additional controls in each primary AOI, Alpine has determined that these three Class I areas³ will be unable to achieve a level of emissions reduction necessary to bring these areas under the reasonable progress line. Influences such as incrementally uncontrollable source categories, cost-effectiveness limitations and international and inter-RPO emissions transport are barriers that prevent strategies from being configured for these Class I areas within the confines of the CENRAP domain.

² These areas include Boundary Waters, Wichita Mountains, and Voyageurs.

³ These areas include Big Bend, Breton Island, and Guadalupe Mountains.

Although application of the exhaustive list of available control technologies to sources within the AOIs for each of the Class I areas failing to achieve ICS identified emission reduction targets, emission reductions beyond the base case should not be forsaken as a result. Indeed, *significant emission reductions may be warranted* in order to prepare impacted States and tribes for future attainment demonstrations where these measures may set the basis for defining and meeting future progress goals.

It should be noted that although this report and associated material includes controls for particular sources or source categories as options to consider for further photochemical modeling, it does not necessarily indicate that they will be modeled, and does not imply that these strategies ultimately will be implemented.

Finally, while the this methodology was developed and tested for regional haze control programs, with very minor adaptation, the same methods can be used effectively to aid in the design of regional 8-hr ozone and annual $PM_{2.5}$ NAAQS attainment strategies.

1.0 INTRODUCTION

The Implementation and Control Strategies (ICS) Workgroup of the Central Regional Air Planning Association (CENRAP), together with other workgroups and state, tribal and federal agencies, have worked for more than four years in developing the foundation for constructing regional haze (RH) control strategies for pertinent Class I areas (Table 1-1) within and adjacent to the CENRAP states and tribes (Seltz, 2006a,b; Anderson; 2005; Sharp and Anderson, 2005). In late February 2006, Alpine Geophysics, LLC (AG) was contracted to assist the ICS in these ongoing efforts. Specifically, using information developed by the ICS and others, AG was charged with developing a quantitative procedure to identify and prioritize potential RH control strategies to be tested by CENRAP modelers. Alpine formulated a methodology for constructing control strategy recommendations based on presently available information and submitted a Work Plan detailing this approach to the ICS/CENRAP leadership for review (Tesche and Stella, 2006).

Based on comments received, the approved Work Plan was implemented, culminating in the quantitative methodology for identifying potentially viable regional haze control strategies for the CENRAP states and tribes. Using the most pertinent aerometric, emissions and air quality modeling data available, we implemented this methodology and, in this report, present a set of recommendations for regional haze precursor emissions reduction strategies. These recommendations, once reviewed and refined by the ICS and Modeling workgroup, will be passed on to the CENRAP Emissions and Air Quality Modeling contractors (ENVIRON International Corporation and the University of California, Riverside) for quantitative testing with the SMOKE/CMAQ/CAMx regional modeling systems.

To facilitate subsequent use of this methodology, this report describes the various analytical steps and provides examples (both in the body of the report and in supporting appendixes). In addition, relevant technical support information, data sets, and analysis software have been supplied to CENRAP for posting on their project website for access by interested parties.

1.1 Study Overview

Preliminary (Typ02a) and more recent (Typ02b) modeling projections from the CMAQ Base18b/Typ02 scenarios (Morris et al., 2006b) have indicated that some Class I areas within or near the CENRAP domain may achieve the 2018 Reasonable Progress Goals (RPG) under current ‘on-the-books’ and ‘on-the-way’ controls while others may not unless additional emissions reductions are implemented (see Figures 1-1 and 1-2). As shown in Figure 1-1, six CENRAP Class I Areas (Big Bend, Guadalupe, Wichita Mountains, Breton Island, Voyageur, and Boundary Waters) are projected, by the latest CMAQ modeling, to have somewhat higher visibility metrics (deciviews) when compared to the 2018 RPG glide paths. While Boundary Waters does not explicitly appear in Figure 1-1 due to data base insufficiencies, recent modeling by various RPOs suggests that Boundary Waters responds similarly to Voyageurs. Accordingly, it is thus included as one of the six projected Class I areas where additional precursor controls might be considered by CENRAP/ICS.

Figure 1-1. Current Visibility Projections (Base 18d/Typ02b) at CENRAP and Other Class I Sites (Source: Morris et al., 2006b).

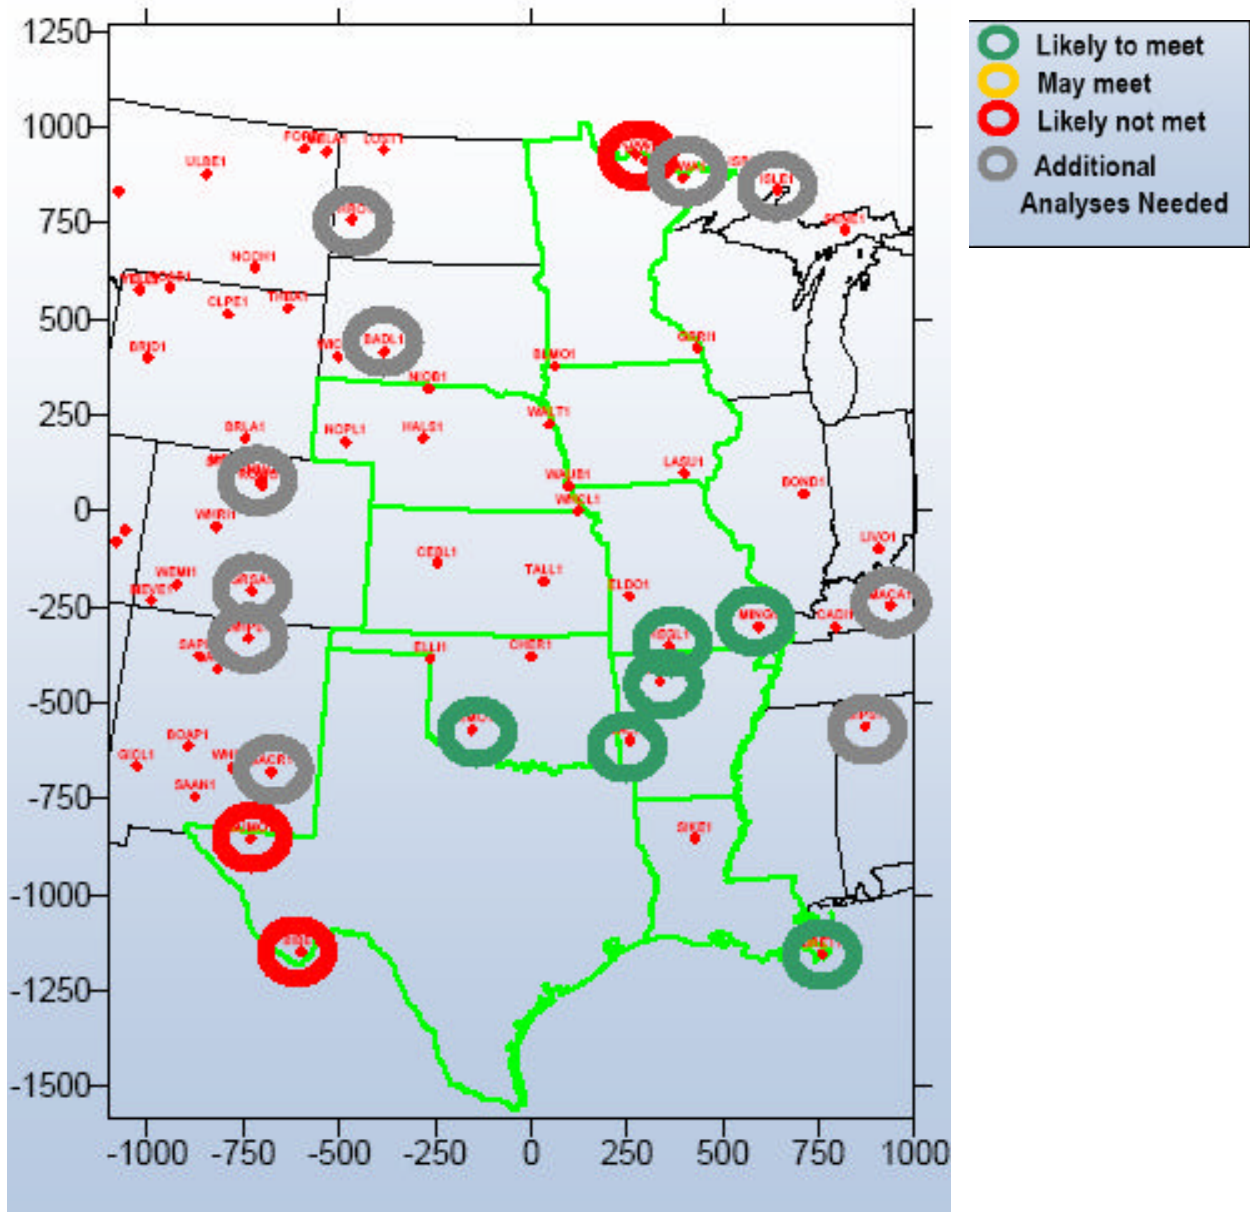

Figure 1-2. Preliminary Visibility Projections by State (Source: Morris et al., 2006b)

To prepare for the modeling of potential additional control strategies, an intensified effort has been undertaken by the ICS work group over the past two years to ‘set the stage’ for this activity (see for example ICS, 2005, Seltz, 2006). Consonant with these plans and on behalf of CENRAP, the ICS workgroup seeks to integrate focused contractor support with ongoing workgroup activities to accomplish the following objectives:

- > Analyze existing regional haze modeling inventories developed by CENRAP, the States, tribes, and other RPOs;
- > Synthesize available and pertinent air quality and meteorological data and recent ‘attribution of haze studies’ by CENRAP and the other RPOs;
- > Review preliminary 2018 RPG modeling by CENRAP and other RPOs to identify the key Class I areas for which additional emissions reductions may be needed;
- > Develop a prioritized set of regional and subregional precursor emissions control scenarios aimed at achieving the RPG at the CENRAP Class I areas; and
- > Monitor the initial 2018 control strategy modeling performed by the CENRAP modeling team to ascertain whether subsequent strategies need to be refined or new strategies developed.

The project Work Plan (Teschke and Stella, 2006) describes in detail how these objectives have been addressed in cooperation with ICS and CENRAP.

1.2 Approach, Assumptions, and Constraints

Development of recommendations for potential CENRAP regional haze control strategy simulations was a three-step process. First, we assembled available information useful in quantifying the reductions in fine particulate aerosol concentrations needed to satisfy CENRAP’s preliminary regional haze visibility projections. Naturally, the principal focus was on the Class I areas within the CENRAP region that were estimated to not meet the 2018 Reasonable Further Progress (RFP) glide paths. Based on preliminary and more recent modeling (Morris et al., 2006b), some Class I areas did meet the 2018 RFP glide paths while others did not. As new visibility projections for the Class I areas become available, the ICS may wish to re-examine this study’s strategy recommendations in order to account for more up-to-date estimates.

The second step involved developing Areas of Influence (AOIs) upwind of each Class I area within which common ‘visibility precursor-Class I receptor’ impacts could be aggregated into similar groupings. We used results of numerous statistical and pattern recognition studies, as well as pertinent regional photochemical aerosol modeling by Alpine and ENVIRON scientists as well as other groups (including the RPOs). These analyses culminated in quantitative ‘rules of thumb’ relating emissions reductions of visibility-impairing precursors (in tons/day) to ambient aerosol concentrations at each of the ten (10) CENRAP Class I monitors. We also developed these quantitative source-receptor relationships for a dozen Class I areas in adjoining RPOs to the extent possible given available data, project resources and schedule. As of this writing,

CENRAP Modeling contractors are still performing focused particulate source apportionment modeling (CAMx PSAT) over the region. Once this work is completed, the ICS may wish to re-examine our methodology and strategy recommendations to determine if refined source-receptor relationships alter in any way our present findings and conclusions.

The third step synthesized the results of the first two, together with information on the estimated 2018 CENRAP emissions inventory and the cost-effectiveness of various controls, to deduce a prioritized set of RH control strategies containing elements of both regional emissions reductions and targeted reductions within the AOIs closest to those six CENRAP Class I areas for which positive visibility increments were estimated (Morris et al., 2006b). We used the most up-to-date modeling inventory supplied by the CENRAP Modeling contractor; however, the current round of inventory corrections and refinements will undoubtedly lead to refined emissions data sets in coming months. Thus, another constraint limiting the ‘shelf-life’ of this study’s recommendations is the accuracy and representativeness of the draft 2018 emissions data used in developing this plan’s precursor emissions control recommendations.

While project work scope precluded re-running the strategy development process described in this report with updated CAMx/PSAT and CMAQ visibility projections expected in late May or early June 2006, the methodological tools are cataloged and archived should the ICS wish to undertake this activity at a later time.

1.3 Structure of Report

This report is organized as follows. Section 2 provides a brief background on the Regional Haze Rule (RHR) and the role that CENRAP and the other RPOs are playing in developing strategies that will show progress in meeting Reasonable Progress Goals by 2018. We also discuss key considerations that influence the design of regional and subregional control strategies in the context of the RHR. Our technical approach is summarized in Section 3. Details of our methodology are given in the Work Plan (Tesche and Stella, 2006a). In Section 4 we describe the information available to characterize the daily and annual composition of PM_{2.5} constituents (sulfate, nitrate, elemental carbon, etc) at the various IMPROVE monitors in the CENRAP and adjoining Class I Areas. We also describe the method to relate the modeled deciview (dv) or extinction coefficient (Mm^{-1}) – derived from the most recent CENRAP visibility projection modeling – to the fine particulate component concentrations at each Class I area expressed in units of mass per unit volume (i.e., $\mu g/m^3$).

Section 5 presents the quantitative methods for converting these concentration increments (whose reductions will likely achieve the individual Class I areas visibility goals by 2108) to mass emissions rate reductions for the primary particulate aerosol precursors, NO_x and SO₂. In addition, the section describes the methods used to construct Area of Influence (AOI) domains surrounding each Class I area based on historical data analysis, statistical pattern recognition studies, and various photochemical and aerosol modeling studies performed throughout the eastern U.S. by Alpine, ENVIRON, state, tribal and federal regulatory agencies, the Southern

Appalachian Mountains Initiative (SAMI), the RPOs, and university scientists⁴. In Section 6, the information developed in the two preceding chapters is used, together with original analyses of the 2018 regional haze inventories and control technology cost-effectiveness information, to construct a series of curves from which quantitative estimates of suggested precursor emissions controls (within specific AOIs) are developed for each Class I Area in CENRAP projected above the reasonable progress glide path in 2018. Our summary and recommendations are presented in Section 7.

1.4 Technical Support Resources

Several technical appendixes and support documents are provided to accommodate the extensive tabular and graphical information underpinning our methodology. Some appendixes constitute simple tabular data or emissions summaries (in Excel format) while other appendixes contain information in PowerPoint or Adobe Acrobat formats. Finally, the study's Work Plan, Final Report, Technical Support Documents (i.e., the appendixes and other materials), and a compilation of science reports, professional papers and journal articles have been transferred to CENRAP for uploading to their project ftp site.

⁴ The AOI methodology was carried out by Dr. Jim Wilkinson of Alpine whose recent Ph.D. original research and Dissertation from Georgia Tech focused on the development of the AOI methodology for regional haze, ozone, and PM_{2.5} control strategy modeling in the eastern U.S.

2.0 CONTEXT FOR REGIONAL HAZE STRATEGY DEVELOPMENT

Section 169A of the Clean Air Act (CCA) sets forth a national goal for visibility which is the “prevention of any future, and the remedying of any existing, impairment of visibility in Class I areas which impairment results from manmade air pollution.” In 1999, EPA published a final rule to address a type of visibility impairment known as regional haze (64 FR 35714). The Regional Haze Rule (RHR) requires States to submit implementation plans (SIPs) to address regional haze visibility impairment in federally-protected parks and wilderness areas (i.e., the Class I scenic areas identified in the Clean Air Act). The 1999 rule was issued to fulfill a long-standing EPA commitment to address regional haze under the authority and requirements of sections 169A and 169B of the CAA. In essence, the RHR prescribes that states are to make efforts to improve visibility in 156 Class I areas at such rates that “natural conditions” would be achieved in each area by 2064. A ‘reasonable rate of progress’ corresponds to linear improvement in visibility, as characterized in units of deciview (dv), between current conditions during the base period of 2000-2004 and natural conditions at the end point of 2064. It is important to note that a modeled 2018 visibility condition at a Class I monitor – numerically equaling the monitor’s RPG goal – is not meant to imply ‘attainment’ of any standard nor is lesser modeled progress in reaching a particular RPG indicative of ‘nonattainment’. Indeed, as will be discussed later, progress in attaining visibility improvements at some CENRAP monitors (in Texas and Minnesota) may be thwarted by substantial contributions of visibility precursors from Mexico and Canada over which the States and Tribes have no direct control.

2.1 Role of CENRAP and the Other Regional Planning Organizations (RPOs)

CENRAP is one of five Regional Planning Organizations (RPOs) that have responsibility for coordinating development of State Implementation Plans (SIPs) and Tribal Implementation Plans (TIPs) in selected areas of the U.S. to address the requirements of the Regional Haze Rule (RHR). The RHR visibility SIPs/TIPs are due in 2007/2008. CENRAP modeling results may also form the regional component for 8-hour ozone and fine particulate (PM_{2.5}) SIPs/TIPs that are also expected to be due in 2007/2008. CENRAP is a regional partnership of states, tribes, federal agencies, stakeholders and citizen groups established to initiate and coordinate activities associated with the management of regional haze and other air quality issues within the CENRAP states. The CENRAP region includes states and tribal lands located within the boundaries of Arkansas, Iowa, Kansas, Louisiana, Minnesota, Missouri, Nebraska, Oklahoma and Texas.

The regional emissions and fine particulate/visibility modeling for CENRAP is being performed by the Emissions and Air Quality Modeling Contractor that is comprised of staff from ENVIRON International Corporation (ENVIRON) and the University of California, Riverside (UCR). The ENVIRON/UCR team performs the emissions and air quality modeling simulations for states and tribes within the CENRAP region, providing analytical results used in developing implementation plans under the EPA Regional Haze Rule. Alpine Geophysics serves as the Technical Advisor to CENRAP, working interactively with the emissions and air quality modelers at ENVIRON and UCR.

2.2 Considerations in Designing Regional Haze Control Strategies

Where the year 2018 base case modeling does not show an acceptable regional haze or visibility glide slope for a Class I area within or adjacent to the CENRAP domain, additional (and possibly substantial) emission reductions will most likely be required to show reasonable progress in meeting 2108 visibility goals. Due to the unique location, meteorology, and emission sources within an area of influence to each Class I area, individualized control strategies reducing emissions from the remaining residual sources or source types are most likely to achieve required results. It is highly unlikely that a single cost effective “across-the-board” reduction strategy will achieve the visibility goals for every Class I area.

Although emissions located within areas of direct proximity to Class I area monitors will generally have the greatest influence on attaining visibility goals, these sources may not be the only ones with significant impact on the air quality. Using methods such as localized geography analysis (e.g., within 200km of Class I area boundaries) to initially identify source types and pollutants with the greatest influence will only provide part of the picture. In reality, other methods will also provide information related to transport sources impacting a Class I area. These other methods can include back trajectory analysis, residence time probability, source apportionment modeling (PSAT, OSAT, TSSA), and the cause of haze (COH) studies performed in the past two years by the various RPOs including CENRAP. Other geographic studies, such as identifying sources that have an impact on more than one Class I area are also warranted. These methods can also help to limit or refine geography, pollutants, or source categories of interest for additional reduction potential in each Class I area.

Using these techniques in addition to review of the future year base case emissions inventories and assigned control strategies will allow CENRAP and the ICS Workgroup to further define incremental reduction allowing for the attainment of Class I area air quality or visibility objectives.

2.3 Resources Available to this Study

The reference section of this report and the technical discussions in Sections 4 through 6 identify the major data bases, reports, modeling output files and other resources used in this study. Certain regional modeling and data analysis studies performed by the RPOs and their contractors were particularly useful in developing source-receptor relationships for the various Class I areas. These include: (a) the recent (25 April 2006) visibility projections for the CENRAP and adjoining RPOs recently described by Morris et al. (2006b), (b) monitoring information for the various Class I areas of interest, summarized on the IMPROVE website, and (c) the most recent 2018 SMOKE emissions inventory developed for CENRAP by various state, tribal and federal agencies and contractors.

3.0 TECHNICAL APPROACH

As described in the Work Plan (Tesche and Stella, 2006b), our technical approach consisted of six (6) tasks which are summarized briefly here to provide background for the more detailed technical discussions given in subsequent chapters.

Task 1: Synthesize Relevant Regional Haze Aerometric Analyses: The objective of Task 1 was to synthesize pertinent ‘attribution of haze’ documents, CENRAP CAMx/CMAQ visibility modeling results, and other technical reports, papers, and analyses bearing directly on the quantification of emissions-source/visibility-receptor impacts at the 10 CENRAP Class I areas and adjoining areas. This Task was aimed at quantifying what is known about source-receptor relationships at the 10 CENRAP Class I areas on the basis of emissions, air chemistry and meteorological statistical analyses and receptor modeling studies.

Task 2: Review Existing Inventories and Control Scenario Strategy Options: This involved a concise summarization of existing regional haze modeling inventories and associated local, State, Tribal and Federal control programs to determine available incremental controls on sources or source types affecting visibility increments (i.e., differences between the modeled 2018 visibility level and the RFP glide slope for the particular Class I Area). In addition, we attempted to confirm future year control plans and reduction scenarios necessary to accomplish incremental reduction analysis. The product of this effort was a set of suggestions for alternate incremental control strategies based on analysis of available emissions, monitoring, and modeled data.

The Task 2 review was conducted in a top down fashion starting with an analysis of the major source categories in the domains of interest (based on results from Tasks 1 and 3) to determine which major categories have the highest residual contribution to the area. Once the highest source types were identified, subcategories within those source types were reviewed. In addition to reviewing the residual emission categories in the future year base, we also identified reductions that have already occurred within each category or at specific units. This allows CENRAP to determine if certain source categories that have yet to be controlled under the base case have the potential for reduction or if source types already reduced have reached the full cost-effective potential. Finally, unit level tables of emission comparisons from 2002 to 2018 were developed that facilitate ICS’s review of existing emission reductions and the assignment of new cost-effective controls to units using the best control for the scenario.

Once the list of potential sources available for reduction were identified, we used relevant control strategy information extracted from EPA’s AirControlNET (Pechan, 2005) and other sources to further define the most cost-effective strategies for these sources. Since AirControlNET does not allow for the interactive processing of new inventories (it comes preconfigured with inventories and control strategies applied), this extract was performed outside of the AirControlNET model to assign incremental control programs. Finally, we ran every accessible control strategy against the identified source list to develop incremental cost curves necessary to design command and control or cost-effectiveness based control strategies by source or domain. This master list of controls was then used in the development of our final control strategy recommendations.

Task 3: Synthesize Relevant Regional Haze Source Attribution Modeling:

Complementing Task 1, work under Task 3 was aimed at synthesizing key results from recent regional modeling studies helpful relating emissions reductions of visibility precursors (e.g. SO₂, NO_x) in upwind source regions to the improvement in visibility (in deciviews or, alternatively, in Mm⁻¹) at downwind Class I. More specifically, we attempted to extract from available regional modeling studies useful ‘rules of thumb’ relating percentage or tonnage reductions in visibility reducing precursors (e.g., SO₂, NO_x, ammonia, and VOCs) on the expected impact on visibility downwind. These ‘rules of thumb’ or source-receptor relationships were essential in estimating the amounts of precursor emissions to be reduced in regions upwind of each of the various Class I areas.

Task 4: Develop CENRAP Control Strategy Plan: The objective of Task 4 was to assemble the findings and technical work products from Tasks 1 through 3, supplemented with any additional information provided by the ICS Workgroup or CENRAP Modeling contractors, and construct the CENRAP Control Strategy Plan. As described in subsequent chapters, this plan addresses feasible regional haze control strategies with each one including both regional and sub-regional elements.

More specifically, using the results of the most recent CENRAP visibility projection modeling (Morris et al., 2006b), we identified six Class I areas that potentially require additional regional and/or subregional incremental emission reductions to achieve reasonable progress visibility goals. Once an emissions reduction target was determined for each Class I area, we used the master list of controls developed in Task 2 to formulate the CENRAP Control Strategy plan, including cost-effectiveness as a key element. This plan identifies specific source categories (e.g., SIC, SCC, plant ID), and emissions reductions to be implemented. The specificity of the prescribed control scenarios recommended in the plan is sufficient to allow the CENRAP modeling contractors to readily implement the suggested changes through the SMOKE model input stream.

The CENRAP Control Strategy Plan is intended to identify the specific sources and/or source categories where additional control is available with emphasis on known incremental reductions first (e.g., BART). Using this plan as a starting point, CENRAP is equipped to assess the present strategy recommendations and identify any new assumptions (recent or new facility configurations, updated control strategy information from the states and tribes), emergent data sets (e.g., CAMx PSAT modeling; updated 2018 CMAQ visibility projections), corrected modeling inventories, and so on that were unavailable during the three-week time period when this plan was developed.

Task 5: Review Control Strategy Plan With ICS: The project team participated in a teleconference call on 13 April 2006 with the CENRAP ICS Workgroup to discuss the study methodology, findings, and recommendations.

Task 6: Final Report: To the maximum extent feasible within this project’s work scope, we incorporated written responses from CENRAP on the 10 April draft report, culminating in this final document.

4.0 ESTIMATION OF RESIDUAL VISIBILITY IMPROVEMENT NEEDS

The estimation of residual visibility improvement needs (i.e., the aerosol species concentration reductions [mass per unit volume] at each Class I monitor) was performed through three activities: (a) literature review and synthesis, (b) analysis of current CMAQ visibility projections and IMPROVE measurements at the Class I sites, and (c) integration of this information into a computational scheme for use in later tasks.

4.1 Literature Review and Synthesis of Pertinent Source-Receptor Information

Our synthesis of *existing* source-receptor information for the CENRAP and adjacent Class I area was guided by the following set of questions for which specific answers were sought in recent reports, papers, RPO and science meeting presentations, as well as recent one-atmosphere modeling studies. These core questions include:

- > **What aerosol components are responsible for haze?**
 - What are the major components for best, worst and average days visibility days across the CENRAP domain and how do they compare?
 - How variable are they episodically, seasonally, inter-annually?
 - What site characteristics best group sites with similar patterns of major components?
 - How do the relative concentrations of the major components compare with the relative emission rates nearby and regionally?

- > **What is meteorology's role in the causes of haze?**
 - How do meteorological conditions influencing the CENRAP Class I areas differ for best, worst and typical haze conditions?
 - What empirical relationships are their between meteorological conditions and haziness?
 - How well can haze conditions be predicted solely using meteorological factors?
 - What characteristics best group CENRAP Class I sites with similar relationships between meteorological conditions and haze?
 - How well can inter-annual variations in haze be accounted for by variations in meteorological conditions at the CENRAP Class I areas?

- > **What are the emission sources responsible for haze?**
 - What geographic areas are associated with transported air that arrives at sites on best, typical and worst haze days in the CENRAP region?
 - Are the emission characteristics of the transport areas consistent with the aerosol components responsible for haze?
 - What do the aerosol characteristics on best, typical and worst days indicate about CENERAP or upwind emissions sources?
 - What does the spatial and temporal pattern analysis indicate about the locations and time periods associated with sources responsible for haze?
 - What evidence is there for urban impacts on haze at the CENRAP Class I areas and what is the magnitude and frequency when evident?

- What connections can be made between sample periods with unusual species concentrations and activity of highly sporadic sources (e.g. major fires, dust storms)?
 - What can be inferred about impacts from sources in other states, other RPOs and other countries, particularly Mexico and Canada?
 - What refinements to default natural haze levels can be made using ambient monitoring and emission data?
- > **Are there detectable and/or statistically significant multi-year trends in the causes of haze?**
- Are the aerosol components responsible for haze changing?
Where changes are seen, are they the result of meteorological or emissions changes?
 - Where emissions are known to have changed, are there corresponding changes in haze levels?

With these questions in mind, we surveyed the literature relevant to the CENRAP Class I areas in order *to summarize*:

- > **Characteristics of Each CENRAP Monitoring Site**
- Their representation of the Class I area and nearby Class I areas;
 - Relationship to terrain features, bodies of water, etc;
 - Proximity to major point sources, cities, etc.
- > **Meteorological Characteristics of Each CENRAP Monitoring Site**
- Expected mesoscale flow patterns of interest (sea/land breeze, mountain/valley winds, convergence zones, nocturnal jets, etc.);
 - Orographic precipitation patterns (i.e. favored for precipitation, or in rain-shadow);
 - Inversion layers;
 - Potential for transport from cities and other significant sources/source areas.
- > **Visibility-Aerosol Related Data Analyses**
- Descriptive statistics and interpretation for aerosol data- individual components and reconstructed extinction
 - Key aerosol species component spatial and seasonal patterns (e.g., Best 20%, middle 60%, worst 20% reconstructed extinction days and seasonal patterns by site)
 - Spatial and seasonal patterns of aerosol components frequency distributions.
 - Aerosol component data in light of emissions sources, monitoring site settings, back trajectories
 - Results of cluster, CART, and other pattern-recognition analyses to group sites with similar patterns in aerosol component contributions to haze

- > **Back Trajectory Analyses**
 - Results of back trajectory end point data for each CENRAP Class I area;
 - Back trajectory summary statistics residence time by season, best 20% and worst 20% reconstructed extinction and aerosol components for all CENRAP Class I areas;
 - Conditional probability maps for high and low extinction and aerosol components.
 - Results of emissions density maps giving location information, site setting information, etc., and
 - Mesoscale meteorological analyses complementing back trajectories.

Of course, complete answers to all these questions could not be developed in the course of this three week study; however, sufficient information was available that, when distilled into key tabular and graphical summaries, provided a solid foundation for continued efforts in Task 1 and especially Task 2 (discussed in Section 5). Key reports and modeling summaries synthesized during this initial review were supplied to CENRAP for uploading onto the CENSARA project website for easy access by interested CENRAP workgroup members or stakeholders.

4.2 Preliminary Visibility Estimates for Class I Areas

The visibility projection estimates for 2018 available at the time this study was performed (Typ02a) were developed in early 2006 by ENVIRON/UCR and presented at the February CENRAP meetings in Baton Rouge, LA. Appendix B presents these preliminary visibility projections for the ten (10) CENRAP Class I areas and the twelve (12) outlying Class I areas in the WRAP, MRPO, and VISTAS domains. After the draft report had been prepared, Morris et al., (2006b) published an updated set of visibility projections (Typ02b). Given the importance of using the most up to date projections possible, where feasible we repeated our technical work using the updated projections (See Table 1-1 for a visual comparison of the differences). Table 4-1 lists the following information derived from these more recent CENRAP projections of Morris et al., (2006b).

- > Visibility (in dv) on the 20% worst days in 2002;
- > The 2000-2004 visibility baseline (in dv);
- > The 2018 visibility goal (in dv) based on the requirements of the Regional Haze Rule;
- > The CMAQ-forecasted 2018 visibility levels on the 20% worst days;
- > The ‘increment’ in visibility, expressed in dv (calculated as the difference between the 2018 goal and the 2018 forecast. Negative values (presented in red in Table 2) denote that additional visibility improvement needed to achieve the desired 2018 progress goal; and
- > The ‘increment’ in visibility, expressed in units of inverse mega-meters (Mm^{-1}).

The relationship between deciviews (dv) and inverse megameters (Mm^{-1}) is described in detail by Malm, (1999). Equation 4-1 defines the Haze Index (HI):

$$HI = 10 \ln(b_{ext}/10) \tag{4-1}$$

where *HI* is the haze index (deciviews [dv]) and b_{ext} is the light extinction coefficient (Mm^{-1}). Thus, one deciview is approximately equal to $11.05 Mm^{-1}$ and a change of one dv represents a change of approximately ten percent in b_{ext} , “which is a small but perceptible scenic change under many circumstances”. Malm (1999) provides the following graphical representation between the extinction (Mm^{-1}), deciviews, and visual range (km):

The measured light extinction at the Class I areas for the 20% worst days each year are available at <http://vista.cira.colostate.edu/views/web/AnnualSummaryDev/Composition.aspx>, the IMPROVE site. The most recent measured extinction values (in Mm^{-1}) for the various Class I monitors are listed in Table 4-2, presented in Figure 4-1, and also given in Appendix B. For the most part, IMPROVE extinction measurements for the 20% worst days are available for 2004, the most recent year analyzed. These data are presented as extinction totals for the individual visibility-impairing chemical species: sulfate; nitrate; organic mass; elemental carbon; soil; and

coarse mass. Table 4-3 lists the fractional extinction for each chemical species. Finally, the IMPROVE data for each species at the 22 Class I monitors are presented as a function of time in the appendices to this document. These time series plots reveal the seasonal and daily variation in the visibility-impairing components throughout the year at each site. Figures 4-2 and 4-3 present the absolute and fractional extinction values listed in Tables 4-2 and 4-3 in the form of stacked bar charts for ease of comparison.

4.3 Estimation of Visibility-Impairing Concentration Increments

The information in Tables 4-1 through 4-3 as well as other data provided in the appendices of this document was used to estimate the extent to which additional visibility-impairing precursor emissions reductions might be needed on the basis of current estimates of the projected positive increments and the chemical composition of fine particulate aerosol at the six CENRAP Class I monitors on the worst 20% days. The next step was to transform the visibility increment estimates into concentration increment estimates based on current IMPROVE algorithms. Using the modeled visibility increment (Mm^{-1}) estimates and annual $f(RH)$ values (Table 4-1) together with the measured sulfate, nitrate, OC, EC, soil, and coarse mass fractions from the IMPROVE Class I monitors (Tables 4-2 and 4-3), we deduced the atmospheric concentrations of the six species groups ($\mu g/m^3$) using the standard IMPROVE equation (EPA, 2003). These concentrations were calculated assuming: (a) the required concentration reductions would be met by each precursor in proportion to the most recent IMPROVE distribution at each Class I monitor (Table 4-4); and (b) the concentration reductions would be met by each precursor individually (Table 4-5).

Following the IMPROVE methodology, the relationship between the extinction (Mm^{-1}) of an individual chemical species and the volumetric mass concentration is as follows:

$$b_{\text{Sulfate}} = 3 \cdot f(\text{RH}) \cdot [\text{SO}_4]$$

$$b_{\text{Nitrate}} = 3 \cdot f(\text{RH}) \cdot [\text{NO}_3]$$

$$b_{\text{EC}} = 10 \cdot [\text{EC}]$$

$$b_{\text{OM}} = 4 \cdot [\text{OM}]$$

$$b_{\text{Soil}} = 1 \cdot [\text{Soil}]$$

$$b_{\text{CM}} = 0.6 \cdot [\text{CM}]$$

$$b_{\text{Ray}} = 10 \text{ Mm}^{-1}$$

$$b_{\text{ext}} = b_{\text{Ray}} + b_{\text{Sulfate}} + b_{\text{Nitrate}} + b_{\text{EC}} + b_{\text{OM}} + b_{\text{Soil}} + b_{\text{CM}}$$

The numeric coefficient at the beginning of each equation is the dry scattering or absorption efficiency. The $f(\text{RH})$ term is a monthly-average relative humidity adjustment factor. The terms in the brackets are the concentrations in micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) that will need to be reduced on the 20% worst days at the Class I monitor to make up for the projected visibility 'increment'.

Rearranging yields a solution for the aerosol concentrations as a function of the measured or modeled extinction:

$$[\text{SO}_4] = b_{\text{Sulfate}} / [3 \cdot f(\text{RH})]$$

$$[\text{NO}_3] = b_{\text{Nitrate}} / [3 \cdot f(\text{RH})]$$

$$[\text{EC}] = b_{\text{EC}} / 10$$

$$[\text{OM}] = b_{\text{OM}} / 4$$

$$[\text{Soil}] = b_{\text{Soil}}$$

$$[\text{CM}] = b_{\text{CM}} / 0.6$$

Note that the sulfate (SO_4) and nitrate (NO_3) components are hygroscopic because their extinction coefficients depend upon relative humidity. The concentrations, in square brackets, are in $\mu\text{g}/\text{m}^3$ and b_{ext} is in units of Mm^{-1} . The Rayleigh scattering term (b_{Ray}) has a default value of 10 Mm^{-1} , as recommended in EPA guidance for tracking reasonable progress (EPA, 2003). The effect of relative humidity variability on the extinction coefficients for SO_4 and NO_3 can be estimated in several ways, but given the scope of this analysis, we calculated annual average Class I areas-specific monthly $f(\text{RH})$ values (last column of Table 4-1) from the seasonal $f(\text{RH})$ data provided by EPA in the BART guidelines.

Figure 4-1. Measured Extinction Coefficients at Class I Areas Based on IMPROVE Data.

Figure 4-2. Measured Fractional Extinction at Class I Areas Based on IMPROVE Data.

5.0 ESTIMATION OF EMISSIONS REDUCTION NEEDS

5.1 Development of the Areas of Influence (AOI)

To quantify the incremental emissions reductions needed to ameliorate positive visibility increments at Class I areas, it was first necessary to identify those regions that adversely impact visibility at the Class I areas. These Areas of Influence (AOI) directly identify the source regions whose emissions impact a Class I area. Further, an AOI can also be constructed such that it provides a quantitative assessment of the impact of the emissions from a source region on such metrics as $PM_{2.5}$ concentration at a Class I area. This should not be confused with source apportionment where source regions are assigned quantitative culpability to an overall air quality metric such as sulfate concentration or light extinction. Instead, an AOI ideally describes geographically the emissions source regions and magnitude of, say, the impact that a one ton reduction in SO_2 emissions has on sulfate concentration ($\mu g/m^3$) at a Class I area.

An AOI can be constructed based on a variety of data such as: sensitivities derived from the Decoupled Direct Method (DDM) (Yang *et al.*, 1997; Mendoza *et al.*, 2000); brute force sensitivities; various forms of back trajectory analysis which examine air mass residence time (e.g., Schichtel *et al.*, 2006; DRI, 2005c); and methods that combine back trajectory analyses with such information as emissions impact potential (e.g., Raffuse *et al.*, 2005). Over the last two years, one or more of these methods has been used to construct AOIs or AOI-like diagrams for all the Class I areas of interest to this study. Therefore, it was necessary to identify, gather, and synthesize these data from the many sources so that a consistent set of AOIs could be constructed.

Appendix C is a compendium of AOI data for each Class I area of interest that could be extracted from the body of literature that is available. The first six slides of Appendix C provide examples of the data that were available to construct the AOIs – references are provided on each slide. Ultimately, the Residence Time Difference plots (DRI, 2005c), the Probability of Regional Source Contribution to Haze (PORSCH) plots (Raffuse *et al.*, 2005), the Tagged Species Source Apportionment (TSSA) results (Tonnesen and Wang, 2004; UCR, 2006), and a good deal of engineering judgment were used to construct a consistent set of AOIs for each Class I area.

Residence Time Difference (RTD) plots were constructed based on Back Trajectory Residence Time (BTRT) plots. Back trajectory analyses use meteorological fields to estimate the most likely geographical path an air mass traversed to end at a particular receptor. Of note, the meteorological field can be based on interpolation of observations, modeled (e.g., from a prognostic meteorological model such as MM5), or a hybrid field based on combined modeled and observed values. The method essentially reverses the wind field, moving an air mass backward in time. Back trajectories oversimplify actual atmospheric conditions in that dispersion is ignored. Further, the potential emissions source regions that impact a receptor are underestimated given that it is impossible to track every air parcel impacting the receptor.

The BTRT estimates that were developed by DRI (2005b) and used in this study were estimated using HYSPLIT (Draxler and Hess, 1997; NOAA, 2006). HYSPLIT uses archived three dimensional meteorological fields generated from observations and short-term meteorological forecasts. The model produces a series of endpoints representing longitude, latitude, and

elevation of the parcel at one-hour intervals. BTRT plots at each site were calculated for all days, by month, and by best and worst twenty percentile days (DRI, 2005c). BTRT plots give the fraction of total hours that an air parcel resided over each specific geographical area. RTD plots were created by subtracting the map for all days at a site from the map for the 20% worst days by pollutant. RTD plots were computed for the twenty percentile worst sulfate, nitrate, organic carbon, elemental carbon, fine soil, and coarse mass days.

The worst twenty percentile sulfate RTD plots, for example, shows the difference in residence time between the worst sulfate days and all days. If the number is positive, then the residence time on the worst sulfate days is greater than on all days. The residence time difference map simply shows the areas that air was more frequently (positive numbers) passing over on worst case days compared to all days.

The PORSCH system is a suite of GIS tools that combines modeled backward wind trajectories, monitored concentrations, meteorological conditions, and emissions estimates to estimate probable regions of influence. PORSCH combines ensemble backward trajectories with chemically speciated emissions data to estimate the trajectory-emissions density-weighted area likely to impact a receptor site. PORSCH can do this for a single day or a suite of days though for purposes of this study, only data relevant to the 20% worst haze days were extracted.

As the name implies Tagged Species Source Apportionment (TSSA) uses “Tagged Chemical Species,” or tracers, to track chemical transformations and transport of each chemical species or precursor species during an air quality model run. Key chemical species are identified for specific emissions source regions or emissions source categories. These tagged chemical species are tracked during all phases of the air quality modeling run (e.g., advection, diffusion, deposition, chemical transformation), and the end results are three dimensional fields in time showing source attribution of the chemical species for any grid cell in model domain. When chemical species are tagged by emissions source region, this provides valuable corroborative evidence for identifying key AOI regions.

Slides 8 through 82 of Appendix C contain the raw data that was extracted from the literature base, which served as the foundation to develop the AOIs for the ten CENRAP Class I areas. Slides 84 through 184 of Appendix C contain the raw data from which AOIs were synthesized for the nine WRAP and two VISTAS Class I areas that border the CENRAP states. Because RTD plots were available for the entire suite of twenty-one Class I areas, they served as the primary basis from which the AOIs were estimated. The RTD plots were manually examined to determine “natural break-points” in residence time difference (only positive values were considered in these plots as positive values indicate air mass residence was greatest in these geographical areas on the 20% worst haze days).

In many cases, these “natural break-points” were difficult to determine given that the scales on the RTD plots were not consistent; hence, engineering judgment was used to place a “break-point.” For virtually all Class I areas, it was possible to determine at least two “break-points” and in some instances, three and four “break-points” were determined. For purposes of this effort, a “break-point” was generally placed where the residence time difference transition was on the order of a factor of ten and over large geographical areas. Little pockets of large RTD transitions, such as might occur over Lake Michigan or the Gulf of Mexico, were merged into a

larger “break-point.” Once a “break-point” was determined, a hand drawn contour was placed on the plot to indicate the Level 1, 2, or greater “break-point.” This was done for each of the chemical species classes: sulfate; nitrate; organic carbon; elemental carbon; fine soils; and coarse material, at each Class I area. For clarification purposes, the Level 1 “break-point” is always the smallest polygon closest to the Class I area, and subsequent Level 2, 3, or greater “break-points” cover progressively larger areas.

Once the RTD “break-points” were determined, the plots were manually compared to the supporting PORSCH and TSSA data in order to determine if a “break-point” needed to be expanded, contracted, or moved. The PORSCH data were used primarily to determine if the spatial extent of a “break-point” was adequate and the TSSA data were used to determine if the areas of emissions impact potential were captured within the spatial extent of the RTD “break-points.” Based on this reconciliation effort, the Level 1, 2, or greater “break-point” contours were manually adjusted on the plots. Again, a great deal of engineering judgment was used in how these data were combined. This initial effort resulted in the development of 126 plots (six pollutants times twenty-one Class I areas) consisting of one or more “break-point” contours.

Next, each plot was manually compared to the remaining plots to determine if any of the Level 1, 2 or greater “break-point” contours were similar in their geographic placement. If a set of contours from different Class I areas had similar geographic placement, the plots were combined into a single set of contours. In many cases, the “break-point” contours were again manually adjusted so that different plots could be combined into a single set representing multiple Class I areas and multiple pollutants.

This final set of manually created, combined “break-point” contours is what is referred to as the Area of Influence (AOI) for each Class I area. However, these hand drawn AOIs are useless in their current form since it would have been far too time consuming to try to manually extract the counties over which an AOI passed – a step which is necessary if one is to determine the emissions impact potential from a geographic area (i.e., AOI) that impacts a Class I site. Therefore, it is necessary to convert the hand drawn AOIs into a geocoded, electronic file.

Geocoding of the hand drawn AOIs is accomplished by first scanning the image into an electronic file. The scanned image is then registered to a known set of geographical objects. In this case, the geographical objects are the political boundaries of the United States. The function of registering the scanned image, which itself is a political boundaries map of the United States with a set of hand drawn AOIs, is performed using a Geographic Information System (GIS). Secondly, the registered scanned image is rectified so that the image retains its geographic relationship to real world coordinates. Finally, the contours of the rectified image are digitized.

The final set of AOIs is shown in Slides 136 to 143 of Appendix C. These represent the geocoded AOIs that are used to extract a list of counties whose emissions sources have the greatest potential to impact the air quality at a Class I area. Again, ARC/Info was used to extract the counties within each AOI. Figure 5-1 is an example geocoded AOI for the Boundary Waters and Voyageurs Class I areas. Note the distinction between the Level 1 and Level 2 AOIs for both sulfate-to-SO₂ and nitrate-to-NO_x sensitivities.

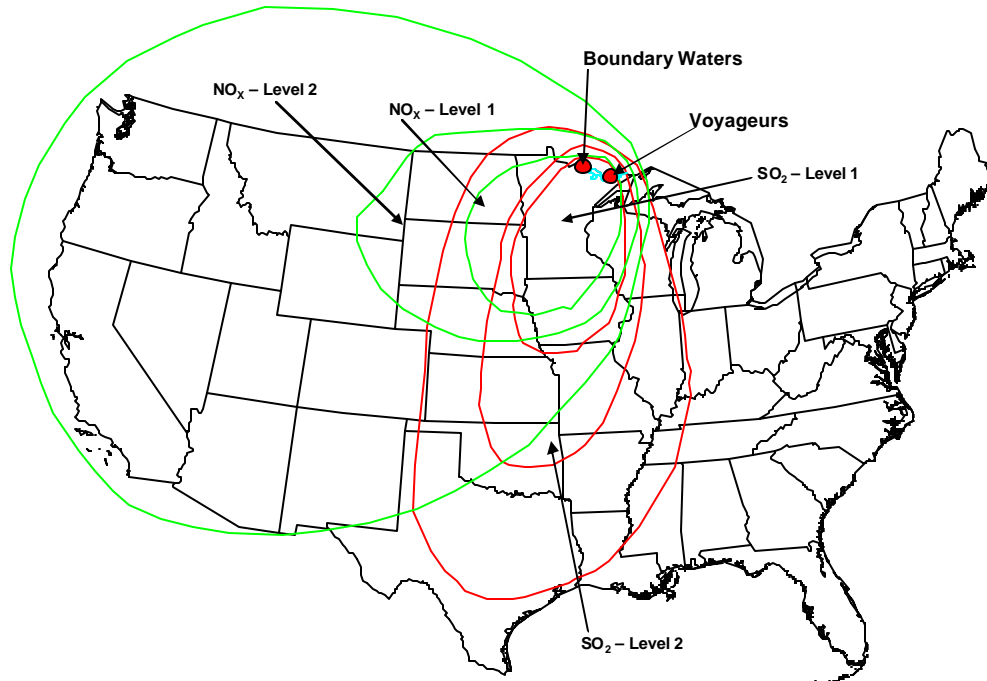

Figure 5-1. Example Geocoded AOI for Boundary Waters and Voyageurs Class I areas. Green contours delineate areas of influence where NO_x emissions impact aerosol nitrate at the Class I areas. Red contours delineate areas of influence where SO_2 emissions impact aerosol sulfate at Class I areas.

5.2 Development of Visibility Impairing Pollutant Concentrations to Precursor Emissions Sensitivity Coefficients

Though a list of counties can now be identified whose emissions sources have the greatest potential to impact air quality at a Class I area, this list has limited value until a quantitative value to associate emissions to air quality is estimated. Ideally, these associative values take the form of $\mu\text{g}/\text{m}^3$ of pollutant reduced per ton per day of precursor emissions reduced. For example, $-0.001 \mu\text{g}/\text{m}^3$ of sulfate per ton per day SO_2 reduced tells one that for each ton of SO_2 reduced within an AOI, the Class I area will exhibit a decrease of $0.001 \mu\text{g}/\text{m}^3$ in sulfate concentration. This value is referred to as a sensitivity value and is very powerful at informing efforts such as those pursued in this study. A great deal of work has been performed to ascertain such sensitivities, and it is from this body of knowledge that sensitivities specific to the current efforts have been derived.

Tesche *et al.* (2003c) conducted a suite of brute force sensitivity runs using the CAMx and CMAQ air quality modeling (AQM) systems over the eastern United States on behalf of VISTAS. By systematically perturbing the global inventory (e.g., reducing global NO_x emissions by 10%) and rerunning the AQM, they developed a suite of metrics that provided the maximum reduction to say the peak, modeled ammonium nitrate. By converting the 10% NO_x reduction to actual tons per day NO_x reduction, which is simply done by taking 10% of the

emissions in the AQM-ready emissions files, and dividing that into the peak concentration reduction, the sensitivity that is of most importance is realized. Though this value is a more global sensitivity, its use is still valid for our needs. Indeed, by assuming that such a sensitivity is valid across the domain, this general purpose sensitivity value can be extended to all the AOIs of interest by computing the value of a 10% reduction in each of the AOIs and dividing this number into the general sensitivity value derived from the average of all the sensitivities, by pollutant of course, estimated by Tesche *et al.* (2003c).

Appendix D shows an Excel workbook containing the summary data (i.e., worksheet named “General”) from Tesche *et al.* (2003c). The worksheet shows the results of the specific sensitivity analyses conducted, and the results of our efforts to compute a general purpose sensitivity value. Once a general purpose sensitivity value was computed, it was recast in a form specific to the Class I areas of interest. This was done by assuming that the general purpose sensitivity (e.g., $\mu\text{g}/\text{m}^3$ sulfate reduction per 10% reduction in SO_2 emissions) was valid across the domain and dividing this number by the tons per day value deduced from a 10% reduction of a precursor pollutant in the AOI of interest.

Though a general purpose sensitivity value was estimated for all Class I areas and AOIs of interest, other sensitivity information that was more specific to certain Class I areas was available from work done at the Georgia Institute of Technology (GIT, 2006). Researchers at GIT conducted numerous brute force sensitivity runs of the CMAQ AQM on behalf of VISTAS.

One component of these efforts was to conduct specific emissions source region and emissions source category sensitivity experiments to determine light extinction sensitivities to a reduction in one ton of precursor emissions at Mingo Wilderness, Upper Buffalo, Caney Creek, Hercules Glade, Breton Island, Sipsey, and Mammoth Cave. The emissions source regions for the GIT efforts (GIT, 2006) included the individual VISTAS states, the clustered CENRAP states, and the clustered MANE-VU states. The GIT (2006) results were extracted and summaries were prepared for the combined Mingo Wilderness-Upper Buffalo-Caney Creek-Hercules Glade AOIs, the Breton Island AOI, the Sipsey AOI, and the Mammoth Cave AOI. The results of these efforts were summarized in Appendix D, Excel worksheet “Class I Specific.”

Finally, the results of the sensitivity summary efforts were combined in order to prepare a consistent set of sensitivity values by AOI. This summary is presented in Appendix D, Excel worksheet “Summary” and in Table 5-1.

Table 5-1. Synthesis of Sensitivity Values for Each Class I Area by AOI level. Units should be interpreted as reduction in nitrate (sulfate) concentration ($\mu\text{g}/\text{m}^3$) per average daily ton reduction in NO_x (SO_2) emissions in the specified AOI Level (see Figure 4-5 for an example of the delineation of the AOI Level).

5.3 Estimated Emissions Reductions Necessary to Attain 2018 Glide Path

Now that the visibility ‘increment’ (Table 4-4 [proportional species reduction] and Table 4-5 [single specie reduction]) and the chemical species-to-precursor emissions sensitivity coefficients (Table 5-1) are known by Class I area, it is a simple matter to compute the annualized, incremental emissions reductions that are needed at each Class I area to attain the 2018 glide path. This is accomplished by dividing the visibility ‘increment’ by the sensitivity coefficient and multiplying by 365.

Table 5-2 shows the required incremental reductions of SO_2 and NO_x emissions that are estimated to be required in order for the Class I areas to meet the glide slope by 2018. The estimated SO_2 and NO_x reductions in Table 5-2 are proportional to chemical species contributions during the 20% worst haze days. In contrast, Table 5-3 shows the estimated SO_2 and NO_x emissions reductions if only one chemical species is reduced. The emissions reductions requirements in Tables 5-2 and 5-3 are reported to two significant figures.

For example, in order for Big Bend to meet the 2018 visibility glide path, approximately 73,000 tons per year of incremental SO_2 emissions reductions (Table 5-2) from SO_2 emissions source

residing in the Level 1 AOI (Figure 5-2) are required assuming that incremental emissions reductions are developed based on a proportional reduction in the chemical species. Hence, in addition to the estimated incremental SO_2 emissions reductions of 73,000 tons per year, estimated incremental NO_x emissions reductions of 8,000 tons per year are also expected to be required. Additionally, incremental emissions reductions in coarse material, soil, elemental carbon, and organic compounds are also necessary if, again, emissions reductions are based on proportional reductions in the chemical species, though these reductions were not estimated given that reasonably available emissions control scenarios exist only for NO_x and SO_2 .

If only one chemical specie is controlled, for example sulfate, then precursor SO_2 incremental emissions reductions from emissions sources located within the SO_2 Level 1 AOI (Figure 5-2) are estimated to be 120,000 tons per year (Table 5-3). On the other hand, if only nitrate is controlled, precursor NO_x incremental emissions reductions from emissions sources located within the NO_x Level 1 AOI (Figure 5-2) are estimated to be 210,000 tons per year.

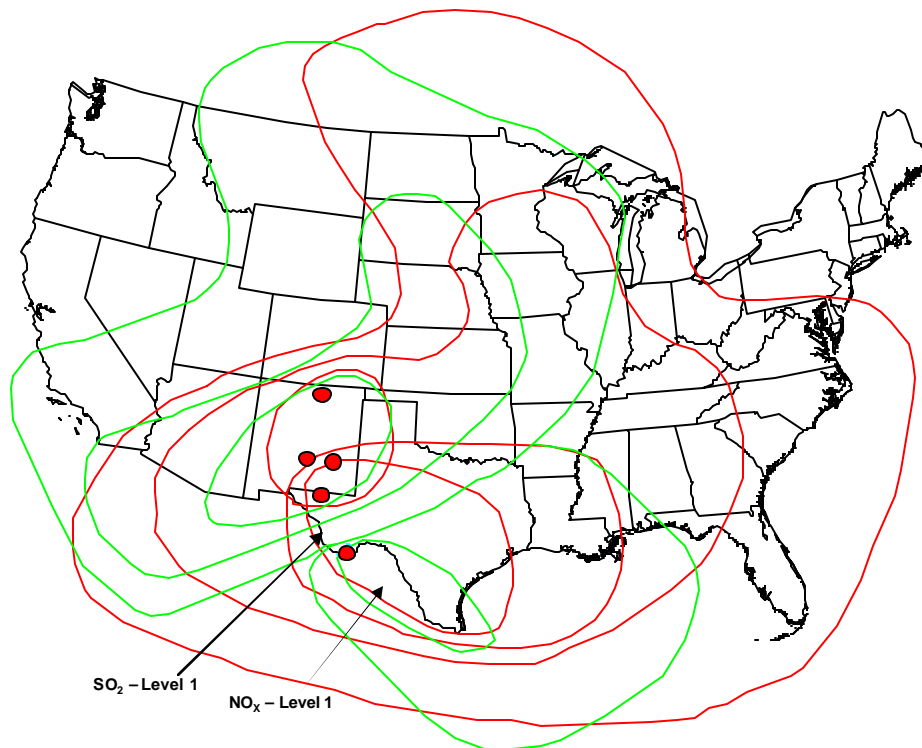

Figure 5-2. Geocoded AOIs for Big Bend, Guadalupe Mountain, Salt Creek, White Mountain, and Wheeler Peak. The Big Bend Level 1 AOI for SO_2 and NO_x are identified.

6.0 PRIORITIZED CENRAP EMISSIONS REDUCTION SCENARIOS

6.1 Summary of Emission Inventories Used in Control Plan Development

A necessary component of the control strategy design is a thorough review of the emission inventories that are used in the modeling of the future year base case. This inventory can shed light on the residual emissions from sources or source categories defined to be within areas of transport or impact of a Class I area. We obtained and used the current CENRAP future year (2018) base case and 2002 base year emissions to conduct a review of the top emitting categories and pollutants within identified impact areas.

The SMOKE-ready modeling files for both 2002 and 2018 base year and base cases were obtained from CENRAP’s emissions modeling contractor (UCR) in addition to a supplementary county level summary of onroad source emissions produced from the gridded, temporalized MOBILE6-based emissions output. Using the annualization methods confirmed with UCR and identified in the SMOKE file headers, each SMOKE input file was converted to annual emissions and summed for the geography and domain of interest.

Tables 6-1 and 6-2 present the major source category breakdown of these emissions for the entire CENRAP domain. AOI-specific breakdowns are presented in Appendix E of this document for those CENRAP Class I areas projected to be above the reasonable progress glide slope. Because the SMOKE-ready files were used in this analysis, the particulate matter transport factor is included in the PM emission summaries. This factor is applied to account for the removal of a substantial portion of fugitive dust emissions near a source by surrounding vegetation and structures when such emissions are used in regional scale modeling analyses.

Table 6-1. CENRAP 2002 Base Year Annual Emissions Summary.

Source Category	CENRAP 2002 Base Year Annual Emissions (Tons)

As 2002 pre- and post-modeled emission summaries were provided on the input data files, we were able to verify the emission totals for each State and SCC in the modeling domain (Pechan, 2006). However, as 2018 summaries were not available in time to review the files for this analysis, we have not confirmed that these 2018 emission totals are as expected by the ICS.

Our review was conducted in a top down fashion starting with an analysis of the major source categories in the domains of interest to determine which major categories have the highest residual contribution to the area. Once the highest source types were identified, subcategories within those source types were reviewed. Again, a ranking of the highest residual sub source types was performed and additional analyses on these categories were conducted. Table 6-3 presents a percentage based contribution of residual emissions by major source category for the CENRAP domain. Tables for each CENRAP Class I AOI projected to be above the glide slope for reasonable progress are presented in Appendix E of this document.

In addition to reviewing the residual emission categories in the future year base, it was important to identify reductions that have already occurred within each category or at specific units. This will allow the ICS to determine if certain source categories that have yet to be controlled under the future year base case have the potential for reduction or if source types already reduced have reached the full cost-effective potential. Table 6-4 presents this information in annual tons for all sources in the CENRAP domain, while Table 6-5 presents the same information in terms of percent change from 2002.

Finally, once each subcategory was identified, unit level tables of emission comparisons from 2002 to 2018 were developed allowing the ICS to review existing emission reductions and providing the ability to assign new cost-effective controls to units using the best control for the scenario. These tables present comparisons of 2002 and 2018 emission levels, by pollutant, and future year control technology assignment (by IPM forecasting) for EGU sources. Since unit-

specific technology assignments were not identified in the SMOKE control packets nor in documentation obtained for use in this project, these units do not have associated future year technology identification data.

Ultimately, the ICS' final control strategy decisions will include the application of BART applicable source reductions in the future year base case. However, as these sources and their associated reductions were unavailable for this project, they too are not included in this analysis.

6.2 Process in Preparing Files for Control Plan Modeling

In addition to the SMOKE emission files, the 2018 growth and control packets were obtained from UCR for additional application and verification of future year scenario assignment. Since the CENRAP utilized version of the SMOKE processor does not replace control efficiency, rule effectiveness, and rule penetration values in the output files generated using the growth and control modules of the model, Alpine manually applied these values to the 2018 non-EGU and stationary area source files for which the packets were applied. This step was necessary to duplicate the inventories that went into the results of CENRAP's reasonable progress modeling and to ensure that any incremental assignment of control technologies did not duplicate emission reductions already assumed in the future year base case.

The 2018 IPM file used by CENRAP for EGU sources was also obtained and matched to the 2018 base case inventory of EGU sources. This step was conducted for reasons similar to those identified above for non-EGU and stationary area sources and to ensure that incremental controls assigned to these source types did not duplicate existing base case assumptions. Because IPM does not assign a control efficiency with each control device applied to SO₂ and NO_x, we made some assumptions, based on IPM documentation, as to what pollutant specific level of reduction was applied in the future year base case runs. These assumptions, by primary and secondary control device code combinations for SO₂ and NO_x, are presented in Tables 6-6 and 6-7, respectively.

Since many of the control technology control cost equations within AirControlNET require additional unit-level characteristic data, we also made matches of the SMOKE IDA files to CENRAP NIF, EPA NEI, or EPA CAMD CEM data sets to obtain these variables when missing.

Unit level boiler capacity (MMBtu/hr) or NETDC (MW) values are required for capital and operating and maintenance cost calculations for many of the EGU technologies. In cases where these nameplate capacity values could not be identified, emission weighted (based on the final EPA 2002 NEI) were assigned to boilers using a primary (highest emitting) SCC. Table 6-8 presents these weighted capacities. Additionally, stack flow, sulfur content, and primary SCC assignment were necessary to cross-reference available incremental control technologies to the base case emissions inventory data. These variables were obtained where matches could be found, in priority order of CENRAP, CAMD, and EPA datasets, respectively.

Table 6-6. IPM Post Processing Assigned Device Codes and Applied SO₂ Control Efficiencies.

Primary Device Code	Secondary Device Code	Description	CE	RE
0	0	No Control	0	0
119	0	Dry Scrubber	90	100
141	0	Wet Scrubber	90	100

205	204	LOW NOX BURNERS + OVERFIRE AIR	50	100

6.3 Application of AirControlNET Technologies

AirControlNET is a control technology analysis tool developed to support the U.S. EPA in its analyses of air pollution policies and regulations (Pechan, 2005). The tool provides data on emission sources, potential pollution control measures and emission reductions, and the costs of implementing those controls.

The core of AirControlNET is a relational database system in which control technologies are linked to sources within EPA emissions inventories. The system contains a database of control measure applicability, efficiency, and cost information for reducing the emissions contributing to ambient concentrations of ozone, PM₁₀, PM_{2.5}, SO₂, NO_x, as well as visibility impairment (regional haze) from point, area, and mobile sources. PM₁₀ and PM_{2.5} as included in AirControlNET represent primary emissions of PM. The control measure data file in AirControlNET includes not only the technology's control efficiency, and calculated emission reductions for that source, but also estimates the costs (annual and capital) for application of the control measure.

Since the existing version of AirControlNET contains the preprocessed application of control technologies to a predetermined set of EPA emission inventories, direct use of the model in this analysis was not possible. However, Alpine received approval from EPA's Innovative Strategies and Economics Group (ISEG) to modify the AirControlNET version 4.1 source code and data tables in order to make it useful to this study (Sorrels, 2006). The results of the application of this modified version of the code still retain the applicability, efficiency, and cost information from the unmodified version of the source code, but were applied to the CENRAP modeling inventories with updated price index scalars to reflect control costs in 2005-dollars.

Using the modified inventories identified in Section 6.2 above, we ran every available control strategy in AirControlNET against the EGU, non-EGU point, and stationary area source inventories to develop a master list of available, *incremental* control strategies for the entire CENRAP 36 km domain necessary for the ICS to design command-and-control or cost-effectiveness based control strategies by source or domain. Mobile source controls were not processed under this assignment as it would have required multiple iterative runs of the EPA NONROAD and MOBILE6 models to generate the appropriate information. This master list of controls was used in the final development of the control strategy plan as described in the following sections.

Since AirControlNET's control cost equations take into consideration the useful remaining life of installed equipment and estimate the costs of compliance with these measures, two of the four reasonable progress goal considerations (see Section 6.6) are directly met through the results of the model's output.

Table 6-8. Emissions Weighted NETDC (MW) Association.

SCC	Description	NETDC (MW)
10100201	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Wet Bottom (Bituminous Coal)	200
10100202	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Dry Bottom (Bituminous Coal)	500
10100203	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Cyclone Furnace (Bituminous Coal)	200
10100212	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Dry Bottom (Tangential) (Bituminous Coal)	500
10100215	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Cell Burner (Bituminous Coal)	1300
10100218	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Atmospheric Fluidized Bed Combustion: Circulating Bed (Bitum. Coal)	200
10100222	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Dry Bottom (Subbituminous Coal)	400
10100223	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Cyclone Furnace (Subbituminous Coal)	400
10100226	External Combustion Boilers; Electric Generation; Bituminous/Subbituminous Coal; Pulverized Coal: Dry Bottom Tangential (Subbituminous Coal)	500
10100401	External Combustion Boilers; Electric Generation; Residual Oil; Grade 6 Oil: Normal Firing	400
10100404	External Combustion Boilers; Electric Generation; Residual Oil; Grade 6 Oil: Tangential Firing	500
10100501	External Combustion Boilers; Electric Generation; Distillate Oil; Grades 1 and 2 Oil	400

10100701	External Combustion Boilers; Electric Generation; Process Gas; Boilers > 100 Million Btu/hr	200
10100801	External Combustion Boilers; Electric Generation; Petroleum Coke; All Boiler Sizes	600
10101204	External Combustion Boilers; Electric Generation; Solid Waste; Tire Derived Fuel : Shredded	200
10300811	External Combustion Boilers; Commercial/Institutional; Landfill Gas; Landfill Gas	200
20100101	Internal Combustion Engines; Electric Generation; Distillate Oil (Diesel); Turbine	200
20100109	Internal Combustion Engines; Electric Generation; Distillate Oil (Diesel); Turbine: Exhaust	200
20100201	Internal Combustion Engines; Electric Generation; Natural Gas; Turbine	200
	All other boilers	100

6.4 Development of AOI-Based Cost Curves

Each Class I area in the CENRAP modeling domain has an associated set of AOIs as identified in other areas of this document. In order to best determine where emission reduction has the greatest benefit, this geography was designed to limit the available source type list from including all sources within the entire domain.

Using a geocoded county list from these AOIs, we parsed the master list of incremental control measures from all non-mobile source types and sources located within the boundaries of the AOIs. This parsed list was then sorted on an incremental cost-effectiveness (marginal cost) basis to determine the most cost effective control suite necessary to attain emission reduction targets for specific pollutants within each AOI. Each individual source or source category (unit or county-SCC combination) had its own cost effectiveness curve generated. In aggregate, the results of these applications are cost curves for each visibility impairing pollutant for all EGU, non-EGU point, and stationary area source within the geographic domain of the AOI. Incremental controls on mobile sources were not considered in this analysis. An illustrative example of the steps involved with the cost effectiveness curve design can be found in the Appendix F of this document. Figures 6-1, 6-2 and Appendix G present actual cost curves for AOI-1 areas associated with the six CENRAP Class I areas projected to be above the reasonable progress glide path.

6.5 Application of Cost Curves to Emission Reduction Needs

Two sets of cost curves have been developed for each pollutant-Class I AOI-1 combination identified as of interest to the ICS. The first marginal cost curve includes the application of all available control measures to all applicable source types within the AOI. The second curve is the result of limiting the control measure application to only the top three residual emission subcategories identified in the 2018 base case for each AOI-pollutant combination. These two curves will allow the ICS to determine if limiting the control scenario to only the highest residual categories will attain reasonable glide path emission reduction objectives while presumably minimizing the number and type of controlled sources in each AOI.

Within each AOI, an emissions reduction target has been established based on the review of relevant and available regional haze aerometric analyses and source attribution modeling. Each emissions reduction target sets the “solve point” of the cost curve and allows us to identify the most cost effective sources of reduction for the pollutants of interest within each impacted AOI.

It is noted that each pollutant-based cost curve developed for this analysis is mutually exclusive of each other pollutant’s cost curve and does not consider the feasibility of multiple control technologies being applied to any one source. Additionally, the information provided in these cost curves is representative of the primary pollutant of control and does not reflect any co-control applicability or disbenefit as a result of the application of that control.

6.6 Four Factor Analysis for RPG

As part of the regional haze program requirements outlined in 40 CFR 51.308, there are four factors which have been identified as mandatory for purposes of establishing a reasonable progress goal for any mandatory Class I area within a State.

40 CFR 51.308(d)(1)(i)(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal.

6.6.1 Cost of Compliance

The cost of compliance factor is used to determine whether compliance costs for sources are reasonable compared to the emission reductions and visibility improvement they will achieve. Costs should be determined for one-time capital costs and ongoing annual operation, maintenance, and upkeep costs.

Through the application of control technologies using the cost equations from the AirControlNET source code, we have identified individual units for control application, identified the design parameters for emission controls, and developed cost estimates based on those design parameters. An estimation of annualized cost of control, based on a one-time capital cost and continual operating and maintenance costs are included in this estimate, where parameters were available in the AirControlNET equations. This application of control cost analysis as applied to the incremental reduction sources defined in this study meets the application of the cost of compliance statutory factor.

6.6.2 Time Necessary for Compliance

The time necessary for compliance factor may be used to adjust the reasonable progress goals to reflect the degree of improvement achievable within the long term strategy period, as opposed to the improvement expected at full implementation of a control measure, if the time needed for full compliance exceeds the length of the long term strategy period. For example, if vendor availability within the period of the long term strategy could not meet the full requirements of the installation schedule outlined by the control strategy, the reasonable progress goals should reflect the visibility improvement anticipated from installation of controls at the percentage of sources that *could* be controlled within the strategy period.

In this particular analysis, a time necessary for compliance factor could not be determined simply based on the emissions inventory and a list of control measures applicable to controllable sources. An eventual SIP could include control strategies that extend beyond the 2018 milestone and the visibility improvement anticipated from installation of controls at the percentage of sources that *could not* be controlled within the first strategy period would have to be counted in a later SIP. Each of these elements would need to be determined on a unit by unit basis.

6.6.3 Energy and Non-Air Quality Environmental Impacts of Compliance

The energy and non-air impacts factor is meant to consider whether the energy requirements (the amount, type, and availability of energy) of the control technology result in energy penalties or benefits. For example, a particular control may require a fuel, water may be required for a cooling tower, or a landfill may be required for disposal of solid waste byproduct, each which are directly unavailable in the area. Since these impacts are State and site specific, they are not addressed in this analysis. Upon the final configuration of the control strategies by the ICS, each participating State, tribe and affected entity should review the control plan to determine whether significant energy burdens or benefits comes as a direct result of the application of a control technology. If determined to be so, the State should quantify this value and include it in the final submitted SIP.

6.6.4 Remaining Useful Life of Potentially Affected Sources

The statutory factor of the remaining useful life of the source is applicable only to those measures which would require retrofitting of control devices at *existing* sources. The remaining useful life of a source affects the annualized costs of retrofit controls and is included in the methods used for calculating annualized costs in the control cost equations modified from EPA's AirControlNET.

CENRAP's emission projections, as well as the control cost equations applied by Alpine, account for the remaining useful life between the year of the reasonable progress analysis and the date the facility permanently stops operations. Since source specific retirements are taken into consideration with the CENRAP forecasts (units are shut down in the year of their retirement) and average retirement rates are applied to control technologies within the control analysis equations, the statutory factor of the remaining useful life of the source has been considered.

In summary, the basis of our resulting control strategy recommendations provide a demonstration of those reasonable progress goal requirements which could be taken into consideration to meet visibility objectives with the data provided for this analysis. The remaining factors are State, tribal and site dependant and could not be addressed here.

7.0 SUMMARY AND RECOMMENDATIONS

7.1 Summary

Alpine’s review of all data discussed in the previous sections of this document have identified six Class I areas (Big Bend National Park, Breton Island, Boundary Waters, Guadalupe Mountains, Wichita Mountain, and Voyageurs) within the CENRAP domain, their particular AOIs, ICS defined emission reduction targets, and potential incremental emission reductions recommended for CENRAP modeling. For each area, sulfate and to a lesser extent, nitrate reductions were shown to be most beneficial during the 20 percent worst visibility days in 2002.

Alpine has configured subregional control strategies based on direction provided by the ICS to use single precursor emission reduction assumptions with a marginal cost per ton cutoff of \$5,000 per ton reduced. Emission targets were identified by the ICS for each Class I area AOI to exceed the reasonable progress glide slope. These targets were established as 25 percent more reduction than was identified in Table 5-3 and were to be taken from any available source, not just those identified as having the highest residual emissions contribution to the Class I area AOI. Table 7-1 presents a summary of each of these strategies.

Table 7-1. Subregional control strategy summary for single precursor emission reduction targets.

Class I Area	ST	SO ₂ Annual Emission Reduction (Tons)		Control Strategy Total Cost (\$2005)	Control Strategy Average Cost Per Ton (\$/ton reduced)
		ICS Established Reduction Target	Subregional Control Strategy Reductions		
Breton Island	LA	385,000	119,966	\$203,443,093	\$1,696
Boundary Waters	MN	40,000	46,301	\$107,233,124	\$2,316
Voyageurs	MN	28,750			
Wichita Mountains	OK	93,750	99,479	\$21,752,713	\$219
Guadalupe Mountains	TX	162,500	115,936	\$319,001,184	\$2,752
Big Bend Nat'l Park	TX	150,000			

For three of the six CENRAP Class I areas projected to be above the reasonable progress glide slope in 2018, control strategies have been prepared which meet the emission reduction targets recommended by the ICS. These areas (Boundary Waters, Wichita Mountains, and Voyageurs) all can meet the ICS defined targets while staying within the single precursor, \$5,000 per ton reduced limitations.

We also have determined that as a result of the implementation of the list of additional point and area source controls in each primary AOI the remaining three Class I areas within the CENRAP domain (Big Bend National Park, Breton Island, and Guadalupe Mountains) modeled to be above the reasonable progress glide slope will be unable to achieve a level of emissions reduction necessary to bring these areas under the glide slope by 2018 using the ICS identified control strategy definitions. Influences such as incrementally uncontrollable source categories, marginal cost effectiveness values greater than \$5,000 per ton reduced, and international and inter-RPO emission transport prevent strategies from being configured for these Class I areas.

In particular, recent BRAVO research (see, for example Barna et al. 2006) shows that Mexican SO₂ sources account for up to 23% of the observed annual sulfate levels at Big Bend. During the summer months, Mexican SO₂ emissions sources can account for as much as 70% of the sulfate at Big Bend. Barna et al. also show that SO₂ emission sources for the Eastern U.S. are the biggest culprit to high sulfate at Big Bend during the high PM_{2.5} summer days; and SO₂ from the Eastern US and Texas are the biggest contributor to high sulfate at Big Bend during the high PM_{2.5} fall days.

In both of these episode examples, regardless of the emissions reduction achieved by CENRAP with the available source category and technology applications, there still is an emissions component which is directly out of their control. Additional consultation with inter-RPO and international agencies may be required to adequately co-configure strategies to bring these areas into attainment.

7.2 Recommendations

7.2.1 Regional Controls

As each of the six Class I areas projected to be above the reasonable progress glide path (and all of the other Class I AOIs in the CENRAP domain) are dominated by EGU SO₂ and NO_x emissions and many of these area AOIs intersect with States currently excluded by the EPA CAIR rule, *we recommend that CENRAP consider a control scenario which would reduce EGU emissions in non-CAIR States to levels comparable to those promulgated by EPA in the final CAIR regulation.* In addition to this regional strategy proposal, *we further recommend that the ICS consider individual CENRAP States within Class I area AOIs projected above the reasonable progress glide slope to meet CAIR emissions budgets without the interstate trading aspect of the rule.* This nuance may prevent emission reductions from being transferred to areas outside of the influential zones of the affected Class I areas and focus the reductions in those upwind areas with greatest impact on meeting visibility objective goals.

These regional controls could be modeled in multiple ways. Two noted methods being to develop an additional IPM run configured to take into account the CAIR reductions within non-CAIR States with or without the constraint of trading noted above. The second method would be to determine an emission budget (following EPA methods in the CAIR final rule) to determine State level targets for emission reduction. Using these targets, CENRAP could then apply the marginal cost curves developed for this analysis, but limit the solution to only EGU sources identified as “CAIR eligible”. This approach would not take into account any trading or participation in the bank and trade system, but would give an estimate of the regional emission reductions associated with the strategy.

7.2.2 Subregional Controls

In lieu of a single regional control option applied consistently across the entire CENRAP domain, individual subregional controls could be applied to reduce emissions within certain Class I area AOIs. Based on the single precursor emission reduction target calculations defined elsewhere in this document, subregional control strategies can be defined for three of the Class I areas projected to be above the reasonable progress glide path. In each case, the marginal cost

curves (based on the application of all available control options on all controllable industries and source types) allow the selection of control technologies for sources within an AOI-1 that attains the ICS defined emission reduction targets. Details of these control strategies are presented in Tables 7-2 and 7-3. Note that as Boundary Waters and Voyageurs are associated within the same AOI-1, the larger of the two emission reduction targets was used to configure a control strategy that would meet both areas' needs.

However, as noted in this document, the application of incremental control on all controllable point and area sources within the AOIs still fails to meet the visibility objectives of three Class I areas modeled to be above the reasonable progress glide slope. For this reason, *we additionally recommend that the ICS consider applying the remaining reasonably cost effective control technologies to sources within States and tribal lands contained in the boundaries of the three target Class I area AOIs.* As part of the demonstration of reasonable progress, the application of reasonably cost effective controls to all emission sources and source types through a process as described in this document appears to provide support that the four reasonable progress goal considerations were taken into account where available. As is demonstrated for the Boundary Waters and Voyageurs AOI-1 above, the AOI-1 for Big Bend and Guadalupe Mountains share the same emission reduction target. In this case, however, the target cannot be fully achieved. Tables 7-4 and 7-5 present the details of these strategies.

For those Class I areas outside of CENRAP's domain who based on CENRAP modeling did not forecast below the reasonable progress glide slope, we submit to the ICS our data of incremental control strategy application and cost curves based on existing modeling and inventory assumptions provided by CENRAP to date for purposes of consultation with those States in which the affected Class I areas are located. We have not presented these non-CENRAP data as part of this document but much of the basic information is presented, where appropriate, in the supporting appendixes.

Air Planning Section (6PD-L)
Environmental Protection Agency, Region 6
1445 Ross Ave, Suite 1200
Dallas, Texas 75202-2733

**Re: Promulgation of Air Quality Implementation Plans; State of Arkansas;
Regional Haze and Interstate Visibility Transport Federal Implementation Plan;
Docket No. EPA-R06-OAR-2015-0189**

Dear Mr. Donaldson:

Arkansas prides itself on being the Natural State and its ongoing efforts to maintain excellent air quality. The Environmental Protection Agency ("EPA") published on April 8, 2015, a proposed Federal Implementation Plan covering Regional Haze and Interstate Visibility Transport for the State of Arkansas ("Proposed FIP"). The Arkansas Department of Environmental Quality ("ADEQ") has reviewed the Proposed FIP and has determined that it contains significant flaws and does not accurately reflect the real progress the State has made to fulfill the requirements of the Clean Air Act pertaining to Regional Haze and Visibility. EPA failed to use the proper methodology used in portions of the Proposed FIP. Moreover, the Proposed FIP is lacking in its legal precedence and its analysis appears to be incomplete or lacking in clarity. Furthermore, EPA acted arbitrarily in developing a proposal which is inconsistent with the approach taken in other states.

As a primary example of the Proposed FIP's infirmity, the Entergy Independence Plant is not currently identified as being subject to Best Available Retrofit Technology ("BART"). Despite this fact, EPA improperly performed its own reasonable progress analysis. EPA indicated this was performed by applying the reasonable progress factors set forth in the Regional Haze Rule to require specific emissions controls for Entergy Independence Units One and Two. This type of improper and unlawful analysis has no basis in the Regional Haze Rule or other relevant law. Moreover, EPA's proposed additional control measures for the Entergy Independence Plant are both unnecessary and arbitrary. The State of Arkansas has demonstrated that it is on track to meet the uniform rate of progress in its Five-Year Regional Haze Progress Report for the first planning period, which ends in 2018. EPA singled out the Entergy Independence Plant through a cursory evaluation of the National Emissions Inventory data, not a reasoned evaluation utilizing the established framework that takes into account, among other factors, the costs of compliance and progress made to date.

Under the Proposed FIP, certain entities that are already complying with portions of the Clean Air Act aimed at reducing interstate transport of air pollution under the Cross-State Air Pollution Rule ("CSAPR") would also have to install additional emissions controls to achieve the same goal. This is the case despite EPA's own assertions that CSAPR is more effective in reducing particular emissions during ozone season. Based on EPA's statements that CSAPR provides for greater reasonable progress than source-specific nitrogen oxides ("NO_x") controls, EPA should determine that facilities

included in the Proposed FIP which are already subject to requirements under the CSAPR FIP satisfy BART for NO_x and therefore should not be required to install additional controls.

Additionally, ADEQ finds that EPA's Proposed FIP is inconsistent with the approaches proposed in other states. For example, in developing the Proposed FIP, EPA used a simpler modeling method ignoring crucial factors that would provide a more representative accounting of the emissions in Arkansas. In support of this simpler method, EPA cites to its use in developing reasonable progress goals ("RPGs") for Hawaii and Arizona. EPA's decision to utilize this simpler method is not supported in the Proposed FIP. EPA used the CAMx photochemical model in its analysis to develop RPGs for the Texas-Oklahoma FIP. For Arkansas, EPA chose a method of determining RPGs that is admittedly inferior and less sophisticated than the CAMx approach. EPA's inconsistency in methodology is not fully explained and represents arbitrary decision-making that leads to unjustified disparities in treatment among the states.

Furthermore, EPA's metrics used throughout the Proposed FIP are misleading and not supported on a legal or technical basis. For instance, the cumulative visibility effects metric lacks a sound scientific basis and is not supported in the Regional Haze Rule or EPA guidelines. The metric combines slight incremental increases from different locations that do not reflect actual visibility improvement in any single location differently. Ultimately, the metric provides no meaningful information on progress toward meeting visibility goals.

Perhaps most troubling, EPA failed to appropriately assess the costs of the overall impact of the Proposed FIP. Recent concerns have been raised by the United States Supreme Court in the case of *Michigan v. EPA* regarding the rationality of imposing billions of dollars in economic costs in return for a few dollars in health or environmental benefits. Accordingly, EPA should have performed an analysis to properly determine the extent of the impacts of the Proposed FIP in the State of Arkansas.

Finally, it is arbitrary and capricious for EPA to force an emissions source to invest millions, much less billions, of dollars for new technology that will have no appreciable effect on the haze in any Class I Federal area ("Class I area"). In a recent decision that is further discussed in the attached comments, the United States Court of Appeals for the Ninth Circuit recently issued a decision that called into question the use and reliability of the CALPUFF visibility model as a means of identifying affected facilities when those facilities are more than 200 kilometers from a Class I area and the simulated visibility improvements are both within the margin of error of the model and imperceptible. The Clean Air Act does not require an improvement that cannot be reasonably anticipated.

Because of the issues addressed in this letter, ADEQ strongly urges EPA to withdraw the Proposed FIP. In support of this request, ADEQ submits the following comments and asks that EPA pay them the utmost consideration.

Sincerely,

Becky Keogh
Director, ADEQ

Introduction.....	1
The cumulative visibility metrics used throughout the Proposed FIP are misleading and without legal basis in the Regional Haze Rule.....	2
ADEQ concurs with EPA’s determination that the Georgia Pacific Crossett Mill 6A and 9A Power Boilers are not subject-to-BART.....	4
EPA is acting arbitrarily and inconsistently with its own past positions in requiring sources that are subject to the Cross-State Air Pollution Rule (CSAPR) to also control NO _x emissions as BART.....	4
EPA failed to perform the analysis required to establish Reasonable Progress Goals and instead arbitrarily required emissions controls for Entergy Independence Units One and Two.....	8
The Reasonable Progress Goals chosen by EPA are based on admittedly flawed methods that reject the refined modeling approach used by EPA in states such as Texas.....	13
EPA’s revisions to Arkansas’s proposed Reasonable Progress Goals are unnecessary and outside of EPA’s statutory authority to regulate impairment of visibility.	15
It would be premature for EPA to finalize its proposed Reasonable Progress Goals when the Agency intends to significantly revise the manner in progress is determined under the Regional Haze Rule.....	16
EPA’s proposed Reasonable Progress Goals reflect an arbitrary and disparate treatment of Arkansas in comparison to surrounding states.....	17
EPA arbitrarily chose the options for emissions control for Entergy Independence Units One and Two.	22
EPA failed to include the substantial contributions of Federal Land Managers to regional haze in the State’s Class I areas from within the Class II areas themselves.	23
EPA has failed to comply with additional requirements under Executive Order 12866 and Executive Order 13211, and EPA should withdraw the Proposed FIP until such time as it complies with those orders.....	24
ADEQ reserves its right to comment on whether EPA properly made a BART determination for Arkansas facilities, including the Domtar-Ashdown Mill, in light of the Ninth Circuit’s recent opinion in <i>Nat’l Parks Conservation Ass’n v. E.P.A.</i>	28
Conclusion	30

Introduction

In 1977, Congress amended the Clean Air Act (“CAA”) to include the national goal of preventing any future and remedying any existing impairment of visibility at mandatory Class I Federal areas (“Class I areas”). EPA promulgated the Regional Haze Rule in July 1999 to further this national goal and established regulations to eliminate man-made visibility impairment in those areas by 2064. Nationally, there are 156 Class I areas. There are two Class I areas in Arkansas: Upper Buffalo and Caney Creek Wilderness areas.

The Regional Haze Rule and related regulations contain provisions that encourage state, local, and tribal agencies to work cooperatively within regional planning organizations to address visibility impairment. In accordance with the regional haze program requirements outlined in 40 C.F.R. § 51.308, the Arkansas Department of Environmental Quality (“ADEQ”) submitted the Arkansas Regional Haze State Implementation Plan (“Regional Haze SIP”) to EPA on September 23, 2008. On March 12, 2012, EPA partially approved and partially disapproved the Regional Haze SIP (“the Arkansas Regional Haze Approval/Disapproval”).¹

ADEQ submitted on June 2, 2015, the Five-year Regional Haze Progress Report, which is intended to fulfill the requirement in 40 C.F.R. § 51.308(g) that Arkansas provide periodic reports to EPA evaluating progress towards the Reasonable Progress Goals (“RPGs”).

On April 8, 2015, EPA promulgated the Proposed FIP for Arkansas.² On May 1, 2015, EPA extended the public comment period for the Proposed FIP until July 15, 2015.³ ADEQ

comments on that Proposed FIP. Comments are generally presented in the same sequence as the relevant content appears in the Proposed FIP.

The cumulative visibility metrics used throughout the Proposed FIP are misleading and without legal basis in the Regional Haze Rule.

The cumulative visibility effects metric used in many tables and discussions in the Proposed FIP is not scientifically sound, has no legal basis in the Regional Haze Rule, and is grossly misleading. On page 18951 of the Proposed FIP, EPA first uses the term “cumulative visibility benefits” and indicates that this was a factor in its deliberations.⁴ In Tables 8, 10, 11, 13, 18, 20, 21, 23, 27, 29, 37, 38, 42, 47, 49, 51, and 53, EPA adds visibility improvement values at one Class I area to the visibility improvement values at other Class I areas to arrive at a “cumulative visibility improvement.”⁵ This “improvement” referenced in the tables refers to the “cumulative visibility benefits.” EPA does not discuss any purpose for calculating the “cumulative visibility benefits” in the Proposed FIP. Similarly, EPA adds the visibility impacts at individual Class I areas to arrive at a “total visibility impact” in Tables 34, 35, 62, 63, 64, and 66.⁶ EPA also provides no discussion of the origin or purpose of a “total visibility impact” metric. In fact, EPA does not provide a sound scientific explanation for either the “total visibility impact” metric or the “cumulative visibility improvement” metric anywhere in the Proposed FIP.

There is no basis in the Regional Haze Rule or EPA guidelines for either a cumulative visibility metric or a total visibility impact metric. In the “Guidelines for BART (“Best Available Retrofit Technology”) Determinations under the Regional Haze Rule,” EPA only requires an evaluation of the change at each receptor located “at the *nearest* Class I area with sufficient

⁴ 80 FR 18944 at 18951.

⁵ *Id.*

⁶ *Id.*

density to identify the likely visibility effects of the source.”⁷ (*emphasis added*). This requirement is clearly intended to help “identify the likely visibility effects” of the specific visibility improvement of a particular source. Using data from these receptors to create a global visibility increase metric is improper.

Given that the purpose of the Regional Haze Rule is to provide improved visibility in individual and unique Class I areas, adding together slight improvements in visibility from separate areas is not a useful method for measuring overall increased visibility improvement. EPA’s chosen measurement of visibility impairment is a “deciview,” which is defined in part as “uniform incremental changes in perception.”⁸ Many small separate incremental changes in perception in various locations do not create one large uniform incremental change in perception when added together. These metrics simply do not convey any meaningful information related to progress toward reaching the ultimate goal of restoring background visibility conditions at Class I areas.

It is grossly misleading to provide cumulative numbers as a measurement of overall improvement when the incremental changes may only be slight, barely perceptible, and separated by large distances. The methodology behind these metrics lacks any scientific basis. Due to the misleading nature of the cumulative visibility metric and the total visibility impact metric, EPA should withdraw the Proposed FIP and remove all references to either of these metrics in any subsequently proposed plan.

⁷ 40 C.F.R. § Pt. 51, App. Y, § IV, D.5, Step 5

⁸ 40 C.F.R. § 51.301

ADEQ concurs with EPA’s determination that the Georgia Pacific Crossett Mill 6A and 9A Power Boilers are not subject-to-BART.

Chapter III.A.1 of the Proposed FIP contains an analysis of whether BART controls will be required at the Georgia Pacific Crossett Mill 6A and 9A Power Boilers.⁹ In the Arkansas Regional Haze Approval/Disapproval, EPA disagreed with ADEQ’s assertion that the 6A Power Boiler was not BART-eligible and proposed to find that it is BART-eligible.¹⁰

In the Proposed FIP, EPA conducts a further analysis of these boilers and determines that, whether BART-eligible or not, neither boiler has visibility impacts sufficient to be considered subject-to-BART.¹¹ ADEQ concurs that neither of these boilers should be subject-to-BART.

EPA is acting arbitrarily and inconsistently with its own past positions in requiring sources that are subject to the Cross-State Air Pollution Rule (CSAPR) to also control nitrogen oxides (NO_x) emissions as BART.

Presently, Arkansas is subject to a Cross-State Air Pollution Rule Federal Implementation Plan (“CSAPR FIP”) for ozone-season NO_x. Despite EPA’s own guidance stating that CSAPR makes greater reasonable progress than BART for ozone-season NO_x,¹² EPA makes no mention of CSAPR emissions controls in the Proposed FIP and requires BART for Electricity Generating Units (“EGUs”) that are subject to CSAPR. EPA should not require sources that are subject to the CSAPR FIP to also install BART or additional emissions controls based on a reasonable progress analysis, such as is the case with the Entergy Independence Plant.

On May 12, 2005, EPA published the Clean Air Interstate Rule (“CAIR”), which was intended to address interstate transport of air pollution as required by §110(a)(2)(D) of the

⁹ 80 FR 18944 at 18947.

CAA.¹³ The rule affected 28 states and the District of Columbia and included a cap-and-trade program targeting sulfur dioxide (“SO₂”) and NO_x.¹⁴ The rule required 25 states, including Arkansas, to reduce their state-wide emissions of NO_x for the purposes of the 8-hour ozone National Ambient Air Quality Standard (“NAAQS”) by specifying ozone-season NO_x emissions budgets.¹⁵ The emission limitations were intended to reduce or eliminate each state’s contributions to ozone air quality in other states, which would thereby help downwind states meet the 1997 ozone NAAQS. EPA approved Arkansas’s CAIR SIP submission on August 04, 2009.¹⁶ CAIR was heavily litigated and eventually remanded to EPA. However, CAIR remained in effect until EPA could promulgate a replacement, the result of which was CSAPR.

EPA published CSAPR as a replacement to CAIR on August 8, 2011.¹⁷ Similar to CAIR, CSAPR requires certain states to reduce annual SO₂ emissions, annual NO_x emissions and ozone season NO_x emissions to assist with other states’ attainment of the 1997 ozone NAAQS, the 1997 fine particulate matter with an aerodynamic diameter less than or equal to a nominal two and one-half (2.5) micrometers (PM_{2.5}) NAAQS, and the 2006 fine particulate matter with an aerodynamic diameter less than or equal to a nominal ten (10) micrometers PM_{2.5} NAAQS. Initially, CSAPR addressed emissions from Electric Generating Units (“EGUs”) beginning in the year 2012. However, CSAPR was also subject to litigation, which prompted a stay of the rule until litigation was concluded. The Supreme Court upheld CSAPR,¹⁸ and EPA published an

interim final rule on December 3, 2014 revising the CSAPR compliance deadlines.¹⁹ CSAPR became effective on January 1, 2015.²⁰

The Regional Haze Rule allows states to implement an alternative program in lieu of BART so long as the alternative program has been demonstrated to achieve greater reasonable progress toward the national visibility goal than would BART.²¹ EPA proposed that a state in the CAIR trading program would be allowed to rely on EPA's determination that CAIR makes greater reasonable progress than source-specific NO_x controls.²² In the final Transport rule, EPA demonstrated that CSAPR, which replaced CAIR, would make greater reasonable progress toward national visibility goals than would BART.²³

Consistent with the requirements of the Regional Haze Rule, EPA found that the CSAPR trading program did not cause degradation in any affected Class I area.²⁴ In addition, EPA found that CSAPR implementation combined with implementation of BART elsewhere achieved greater visibility improvement on both the 20% best and 20% worst days.²⁵ As a result, EPA found that CSAPR met all requirements under 40 C.F.R. § 51.308(e)(4) to qualify as a substitute for BART.

EPA concluded in the final rule that a state in the CSAPR region whose EGUs are subject to the requirements of the CSAPR trading program for ozone season NO_x may rely on its determination that CSAPR makes greater reasonable progress than source-specific BART. EPA specifically noted that “[t]he states to which this aspect of our final rule applies are *Arkansas*,

Florida, Louisiana, Mississippi and Oklahoma.”(emphasis added).²⁶ Despite EPA’s demonstration that CSAPR makes greater reasonable progress than source-specific BART, EPA has nevertheless proposed NO_x BART for certain units covered by CSAPR in the Proposed FIP.

The approach that EPA has proposed for Arkansas is inconsistent with that taken for other States. EPA promulgated FIPs to replace reliance on CAIR with reliance on CSAPR for the following states: Georgia, Indiana, Iowa, Kentucky, Michigan, Missouri, Ohio, Pennsylvania, South Carolina, Tennessee, Virginia and West Virginia.²⁷ Similarly, Virginia is revising the Virginia Regional Haze SIP to rely on the Virginia CSAPR FIP to meet BART and reasonable progress requirements for SO₂ and NO_x.²⁸

Perhaps most noteworthy, EPA has proposed reliance on CSAPR in states that border Arkansas. The Texas-Oklahoma Regional Haze Plan does not require BART for sources that are subject to CSAPR.²⁹ In that plan, EPA reiterates its position that “CSAPR, like CAIR, provides for greater reasonable progress towards the national goal than would BART.”³⁰ EPA proposes replacing reliance on CAIR with reliance on the trading programs of CSAPR as an alternative to BART for SO₂ and NO_x emissions from EGUs.³¹

Not only is EPA requiring sources subject to CSAPR to control emissions as BART in the Proposed FIP, but EPA has not even considered CSAPR as an option for making reasonable progress. Even if EPA ultimately rejected CSAPR as a means to meet the reasonable progress requirements under the Regional Haze Rule, EPA is required to “cogently explain why it has

³⁰ 79 FR 74818 at 74851.

³¹ 79 FR 74853 at 74818 (the proposed [Texas-Oklahoma] FIP ... substitutes Texas' reliance on the Clean Air Interstate Rule (CAIR) to satisfy BART requirements at its EGUs with reliance on CAIR's successor, the Cross-State Air Pollution Rule (CSAPR))”

exercised its discretion in a given manner.”³² EPA’s failure to consider CSAPR is arbitrary and capricious in light of its treatment of other states.

As a result of EPA’s position that CSAPR provides for greater reasonable progress than source-specific NO_x, facilities subject to the CSAPR FIP should not also be required to install, operate, or maintain BART for NO_x. In Arkansas, the following units should not be required to install the NO_x BART proposed by EPA in the Proposed FIP because they are also subject to CSAPR for ozone-season NO_x: (1) AEP Flint Creek Unit One; (2) Entergy White Bluff Unit One; (3) Entergy White Bluff Unit Two; and (4) Entergy Lake Catherine Unit Four.³³ Accordingly, EPA should withdraw the Proposed FIP and remove the requirements that the aforementioned units be subject to BART in addition to CSAPR emissions controls for ozone season NO_x in any subsequently proposed plan.

EPA failed to perform the analysis required to establish Reasonable Progress Goals and instead arbitrarily required emissions controls for Entergy Independence Units One and Two.

EPA improperly performed its own reasonable progress analysis by applying the reasonable progress factors set forth in the Regional Haze Rule to require specific emissions controls for Entergy Independence Units One and Two. Despite Entergy’s Independence Plant not being identified as subject-to-BART, EPA requires specific emissions controls for the plant in the Proposed FIP under an analysis using four factors intended to aid in establishing unenforceable numerical goals for reducing Regional Haze called “reasonable progress goals.”

³² *Nat'l Parks Conservation Ass'n v. E.P.A.*, No. 12-73710, 2015 WL 3559149, at *3 (9th Cir. June 9, 2015); (citing *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 48, (1983)); *Greater Yellowstone Coalition, Inc. v. Servheen*, 665 F.3d 1015, 1030 (9th Cir.2011) (requiring “a rational connection between the data before [the agency] and its conclusion”); *Nw. Env'tl. Def. Ctr. v. Bonneville Power Admin.*, 477 F.3d 668, 691 (9th Cir.2007)

³³ EPA has included Independence as a “Reasonable Progress Source” in the Proposed FIP rather than a source that is subject-to-BART. This distinction is important as there is no definitive process that EPA has described for determining the degree of control it might require for a specific “Reasonable Progress Source.” Independence, being already subject to CSAPR should not be included in any discussion of BART controls.

This type of analysis has no basis in the Regional Haze Rule or other relevant law. The additional control measures for the Entergy Independence Plant are especially unnecessary in light of Arkansas being on track to meet the Uniform Rate of Progress (“URP”) for the first planning period, which ends in 2018.³⁴

EPA is required to engage in “reasoned decision-making.”³⁵ Not only must an agency's decreed result be within the scope of its lawful authority, “but the process by which it reaches that result must be logical and rational.”³⁶ In *Michigan v. E.P.A.*, the Supreme Court of the United States explained that “agency action is lawful only if it rests ‘on a consideration of the relevant factors.’”³⁷ In the Proposed FIP, EPA has disregarded the framework in the Regional Haze Rule and failed to consider the factors required for establishing Arkansas’s Reasonable Progress Goals (“RPGs”).

EPA’s Regional Haze Rule primarily addresses visibility impairment from point sources by requiring BART for certain existing stationary sources.³⁸ In contrast to the BART requirements, which are specific to point sources, EPA also requires states to develop broad RPGs to be expressed in deciviews that each state must set based on the URP and the following four factors (“reasonable progress factors”): (1) the costs of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of any potentially affected sources.³⁹

³⁸ 40 C.F.R. § 51.308

³⁹ 40 C.F.R. § 51.308(d)(1)(i)

Notably, the Regional Haze Rule uses the imperative “must” in reference to consideration of both the URP and the reasonable progress factors.⁴⁰ Based on these considerations, either the state, or EPA in the case of a FIP, must set specific numerical goals in deciviews - the RPGs- which are intended to ensure that a state is making progress toward achieving natural visibility conditions.⁴¹

The Regional Haze Rule requires a state, or EPA, to consider both the reasonable progress factors and the URP in setting the RPGs.⁴² However, EPA completely disregards its own framework in the Proposed FIP. Instead of utilizing the four reasonable progress factors in conjunction with the URP to set numerical goals measured in deciviews, EPA applies the reasonable progress factors in order to require emissions controls for Independence Plant Units One and Two, which it refers to as a “reasonable progress source.” Effectively, EPA has applied the reasonable progress factors to the Independence Plant as if it were a BART analysis. Rather than considering the URP in conjunction with the reasonable progress factors, EPA completely dismisses the URP, which Arkansas is on track to meet in the first planning period, by stating that “the URP does not establish a ‘safe harbor’ for the state in setting its progress goals.”⁴³

Furthermore, EPA fails to explain how factors required to be considered in setting specific numerical targets, which are themselves not enforceable, could somehow be used to require specific enforceable limits for a single plant. In 40 C.F.R. § 51.308(d)(1)(v), the Regional Haze Rule states that “[t]he reasonable progress goals established by the State are not directly enforceable.” There is simply no legal justification for the analysis EPA has performed using the

⁴⁰ 40 C.F.R. § 51.308 (d)(1)(i)(A)(“ the State *must*: ... (A) consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources” (emphasis added)); 40 C.F.R. § 51.308 (d)(1)(i)(A) (“In establishing the reasonable progress goal, the State *must* consider the uniform rate of improvement in visibility and the emission reduction measures needed to achieve it for the period covered by the implementation plant” (emphasis added))

⁴¹ 40 C.F.R. § 51.308(d)(1)

⁴² 40 C.F.R. § 51.308(d)(1)(i)

⁴³ See Exhibit 1.

reasonable progress factors set out in 40 C.F.R. § 51.308(d)(1)(A). EPA cites no legal authority for identifying and requiring emissions controls for “reasonable progress sources.” The term “reasonable progress source” does not itself appear in the Regional Haze Rule or related guidance documents.

The state, or EPA in the case of a FIP, is required to “include a demonstration showing how these [reasonable progress] factors were taken into consideration in selecting the goal.”⁴⁴ EPA has not performed this task in the Proposed FIP. EPA meticulously presents its analysis under headings with each reasonable progress factor clearly marked, but this analysis does not explain how those factors were taken into consideration in selecting numerical goals in deciviews as required by the Regional Haze Rule. In fact, EPA makes no mention of the factors required for consideration under 40 C.F.R. § 51.308(d)(1)(A) except in relation to the analysis of “Entergy Independence Plant Units 1 and 2.”⁴⁵

EPA’s arbitrary use of the reasonable progress factors to evaluate the Entergy Independence Plant resulted in EPA foregoing a proper analysis of the reasonable progress factors in relation to the RPGs. Critically, EPA has failed to consider the “costs of compliance” with the RPGs in the Proposed FIP. Although all of the reasonable progress factors are required to be considered in setting the RPGs, the Supreme Court of the United States recently reiterated the importance of considering cost in relation to electric generating units such as the two units at the Entergy Independence Plant. In *Michigan v. E.P.A.*, the Supreme Court held that it was unreasonable for EPA to interpret the phrase “appropriate and necessary” as not including an analysis of costs in implementing the Mercury and Air Toxics Standards for power plants.⁴⁶ In doing so, the Supreme Court stated that “[o]ne would not say that it is even rational, never mind

⁴⁴ 40 C.F.R. § 51.308(d)(1)(i)(A).

⁴⁵ 80 FR 18944 at 18992-18998

⁴⁶ *Michigan v. E.P.A.*, No. 14-46, 2015 WL 2473453, at *7 (U.S. June 29, 2015)

‘appropriate,’ to impose billions of dollars in economic costs in return for a few dollars in health or environmental benefits.”⁴⁷ EPA’s decision to forego any type of analysis involving the reasonable progress factors in relation to setting the RPGs is particularly troublesome in light of the Supreme Court’s concerns about costs in *Michigan v E.P.A.*

EPA asserts that it is appropriate to evaluate Entergy’s Independence Plant “because it is a significant source of SO₂ and NO_x ... even though Arkansas’s Class I areas and those outside of Arkansas most significantly impacted by Arkansas sources are projected to meet URP for the first planning period.”⁴⁸ In fact, Arkansas is projected to meet the URP despite none of the controls specified in the SIP or the Proposed FIP having been installed to date.

EPA singled out Entergy’s Independence Plant through a cursory evaluation of the National Emissions Inventory data that ADEQ provides to EPA annually, which EPA then used in modeling for potential visibility impacts.⁴⁹ In doing so, EPA has ignored its own framework for establishing reasonable progress goals and requiring specific emissions controls for a point source. EPA should have considered the four factors in 40 C.F.R. § 51.308(d)(1)(A) along with the URP as set forth in 40 C.F.R. § 51.308(d)(1)(B) in setting numerical RPGs.

In the Arkansas Regional Haze Approval/Disapproval, EPA rejected Arkansas’s RPGs because the state relied on the URP rather than both the URP and the reasonable progress factors to propose its RPGs. EPA stated that “[u]ntil the State conducts a proper evaluation of the four statutory factors ... we will not know whether different RPGs are appropriate for Arkansas’s Class I areas.”⁵⁰ Just as EPA was unable to determine whether Arkansas’s RPGs were appropriate, ADEQ cannot determine whether the RPGs presented by EPA are appropriate

⁴⁷ *Id.*

⁴⁸ 80 FR 18944 at 18992.

because EPA has failed to perform an analysis of its RPGs using the factors in 40 C.F.R. § 51.308(d)(1) and instead applied those factors to an assessment of controls for Entergy's Independence Plant. Therefore, EPA should withdraw the Proposed FIP, and ensure a proper analysis is included in any subsequently plan.

The Reasonable Progress Goals chosen by EPA are based on admittedly flawed methods that reject the refined modeling approach used by EPA in states such as Texas.

Not only did EPA improperly perform the reasonable progress analysis necessary to establish RPGs, but EPA also used an admittedly inferior method to model Arkansas's RPGs. In supporting the RPGs in the Proposed FIP, EPA substituted a method that relies on "a scaling of visibility extinction components in proportion to emission changes."⁵¹ In support of this method, EPA cites to its use in developing RPGs for Hawaii and Arizona.⁵² EPA offers little in the way of positive support for its choice in the Proposed FIP. Rather, EPA chose a method of determining RPGs that is admittedly inferior and less sophisticated than the alternative approach, which EPA rejected in Arkansas but used in Texas: CAMx photochemical modeling.

EPA admits that it has not performed its own modeling in a manner adequate to develop "refined numerical RPGs."⁵³ EPA seems to acknowledge the infirmity in its modeling by explaining its methodology as follows: "Development of refined numerical RPGs for Arkansas's Class I areas would require photochemical grid modeling of a multistate area, involving thousands of emission sources, unlike the comparatively simple single-source CALPUFF modeling used for individual BART assessments."⁵⁴ EPA further explains that "[d]eveloping all of the necessary input files, running the photochemical model, and post-processing the model

⁵¹ 80 FR 18944 at 18997.

⁵² *Id.*

⁵³ *Id.*

⁵⁴ *Id.*

outputs would take several months at a minimum.”⁵⁵ EPA cites additional reasons for rejecting the approach using photochemical grid modeling such as the part that it is requiring an “update of the emission inventory for Arkansas and surrounding states,” which would include the effects of all EPA and state regulatory actions on point, area, and mobile sources.⁵⁶ EPA states this approach would require “specialized and extensive computing hardware and expertise.”⁵⁷

Despite the additional complexity and time needed, EPA chose to use the more refined CAMx photochemical model in the Texas-Oklahoma FIP.⁵⁸ As evidenced by EPA’s actions in the Texas-Oklahoma FIP, EPA certainly possesses the “specialized and extensive computing hardware and expertise” needed to perform modeling using the CAMx photochemical model. EPA fails to justify this disparate treatment in Arkansas’s Proposed FIP. Instead, EPA arbitrarily used an alternative algorithm to develop RPGs that resulted in admittedly inferior numerical goals.

In fact, the only modelling EPA performed for the Proposed FIP was “comparatively simple single-source CALPUFF modeling used for individual BART assessments.”⁵⁹ EPA used this modeling only to justify additional emissions controls on Entergy’s Independence Plant outlined in the reasonable progress analysis and not in support of the proposed state-wide RPGs.

Given the substantial impact on Arkansas businesses and rate-payers that the potential differences in RPGs would make, ADEQ is troubled by EPA’s decision to forego methods that would ensure the same degree of accuracy for RPGs in Arkansas’s Proposed FIP as in the Texas-

Oklahoma FIP. EPA should withdraw the Proposed FIP, and any subsequent plan should include a method of analysis sufficient to establish “refined numerical RPGs.”

EPA’s revisions to Arkansas’s proposed Reasonable Progress Goals are unnecessary and outside of EPA’s statutory authority to regulate impairment of visibility.

EPA’s revisions to Arkansas’s proposed RPGs are unnecessary and beyond the authority granted by Congress. EPA’s own estimates of the effects of the Proposed FIP are reductions for the 20% worst days of -0.21 deciviews for Caney Creek and -.19 deciviews for the Upper Buffalo.⁶⁰ These reductions would not be visible to the naked eye and are beyond the scope of regulatory regime specifically designed to address “the impairment of visibility.”

The CAA only provides EPA with the authority to regulate the “impairment of visibility.”⁶¹ Visibility extends only to things that humans can see with their naked eyes.⁶² By extension, EPA only has authority to regulate the impairments of visibility that are perceptible to the human eye. A “deciview” is a haze index derived from calculated light extinction, such that uniform changes in haziness correspond to uniform incremental changes in perception across the entire range of conditions, from pristine to highly impaired.⁶³ The human eye can only detect a change in haziness of 1.0 or more deciviews.⁶⁴ Measurements of 0.21 and 0.19 deciviews are both well below amount of haze discernable to the naked eye. Under both the plain language and dictionary definitions of “visibility,” the statute does not provide EPA with the authority to regulate haze below a single deciview, which would be invisible to the naked eye.

⁶⁰ 80 FR 18944 at 18998.

⁶¹ 42 U.S.C.A. § 7491 (“Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, *impairment of visibility* in mandatory class I Federal areas which impairment results from manmade air pollution.”)(emphasis added).

⁶² *E.g.* Webster’s Third New International Dictionary 2557 (1981)(“visible” means “capable of being seen”; “visibility” means “the degree or extent to which something is visible ... [by] the observer’s eye unaided by special optical devices”).

⁶⁴ *e.g.* 79 FR 58302 at 58,303.

EPA's proposed RPGs are more stringent than Arkansas's proposed RPGs in its 2008 Regional Haze State Implementation Plan, which would have ensured that Arkansas is on track to achieve natural visibility conditions by 2064. Arkansas is reducing regional haze in its Class I areas at a higher rate than both the URP, which was approved by EPA, and Arkansas's initial proposed RPGs.⁶⁵ EPA's RPGs in the Proposed FIP are only about 0.2 deciviews lower than those developed by Arkansas.⁶⁶ Even if EPA's RPGs were the result of proper analysis and modeling, the difference between the State-established and EPA-proposed RPGs is insignificant and below the range of human perceptibility. As indicated by the URP, Arkansas is well on track to reaching natural visibility conditions by 2064 and more stringent RPGs than those in Arkansas's 2008 Regional Haze State Implementation Plan are not necessary. EPA should withdraw the Proposed FIP and ensure that revised RPGs in any subsequent plan are within the scope of EPA's authority to address impairment of visibility.

It would be premature for EPA to finalize its proposed Reasonable Progress Goals when the Agency intends to significantly revise the manner in progress is determined under the Regional Haze Rule.

For some time now, EPA has been considering changes to the Regional Haze program's metrics for tracking progress as well as a possible three-year extension of the schedule for submitting updated SIPs currently due in 2018. Just this month, the Air Quality Policy Division of the EPA Office of Air Quality Planning and Standards announced a series of conference calls with representatives of the U.S. Department of Agriculture, the Department of the Interior, and regional, state, local and tribal governments with the following items on the agenda:

- Rulemaking activities including the proposal to delay of the State Implementation Plan (“SIP”) submission deadline to 2021 from 2018, options for the process and schedule for

⁶⁵ See Exhibit 1.

⁶⁶ 77 FR 14604 at 18998, Table 67.

submitting progress reports, and options for revising Reasonably Attributable Visibility Impairment rule provisions;

- Guidance to refocus the visibility tracking metric and framework on the controllable fraction of visibility impairment;
- Guidance to determine what constitutes a long-term strategy providing for reasonable progress

As indicated by the items on this agenda, it is apparent that EPA intends to reconsider the manner in which rates of progress toward the visibility goals of the Regional Haze Rule are determined and calculated. These changes would likely be made through a combination of guidance documents and rulemaking. Due to the EPA's intent to significantly revise the manner in which these metrics are considered, it is premature and unnecessary to revise the RPGs that Arkansas has determined to be appropriate. Accordingly, EPA should withdraw the proposed FIP.

EPA's proposed Reasonable Progress Goals reflect an arbitrary and disparate treatment of Arkansas in comparison to surrounding states.

As pointed out in the Five-Year Progress Report State SIP revision, Arkansas is making substantial progress in addressing regional haze in its Class I areas and is on schedule to meet its own proposed RPGs and the URP for the first planning period.⁶⁷ This means that Arkansas is well on track to reaching background visibility conditions by 2064. Despite this progress, EPA proposed RPGs that are more aggressive than that necessary to achieve the program's goal, which is inconsistent with surrounding states that have wide-ranging RPGs placing them on a path to achieve background visibility conditions well beyond 2064.

⁶⁷ Exhibit 1, at 56.

Arkansas is making considerable progress in reducing regional haze based on its own RPGs. The most recent data from 2011 and the current five-year rolling average shows that visibility impairment is decreasing more rapidly than the URP and Arkansas's proposed 2018 RPGs.⁶⁸ In fact, CENRAP modelling indicates that Arkansas may reach its own 2018 RPGs without additional control measures beyond those described in Arkansas's now-disapproved SIP.⁶⁹ The Upper Buffalo Wilderness area is expected to achieve its 2018 RPG of an improvement of 3.75 deciviews for the 20% worst days without any additional controls on sources.⁷⁰ Similarly, the Caney Creek Wilderness area is on track to achieve its 2018 RPG of 3.88 deciviews of visibility improvement for the 20% worst days.⁷¹ Based on Arkansas's proposed RPGs, Arkansas may reach background conditions in Caney Creek by 2062 and in the Upper Buffalo by 2063.⁷² Any further controls or more stringent RPGs are simply unnecessary to achieve the goal of reaching background visibility conditions by 2064.

⁶⁸ Exhibit 1, at 56.

⁶⁹ *Id.*

⁷⁰ *Id.* at 55.

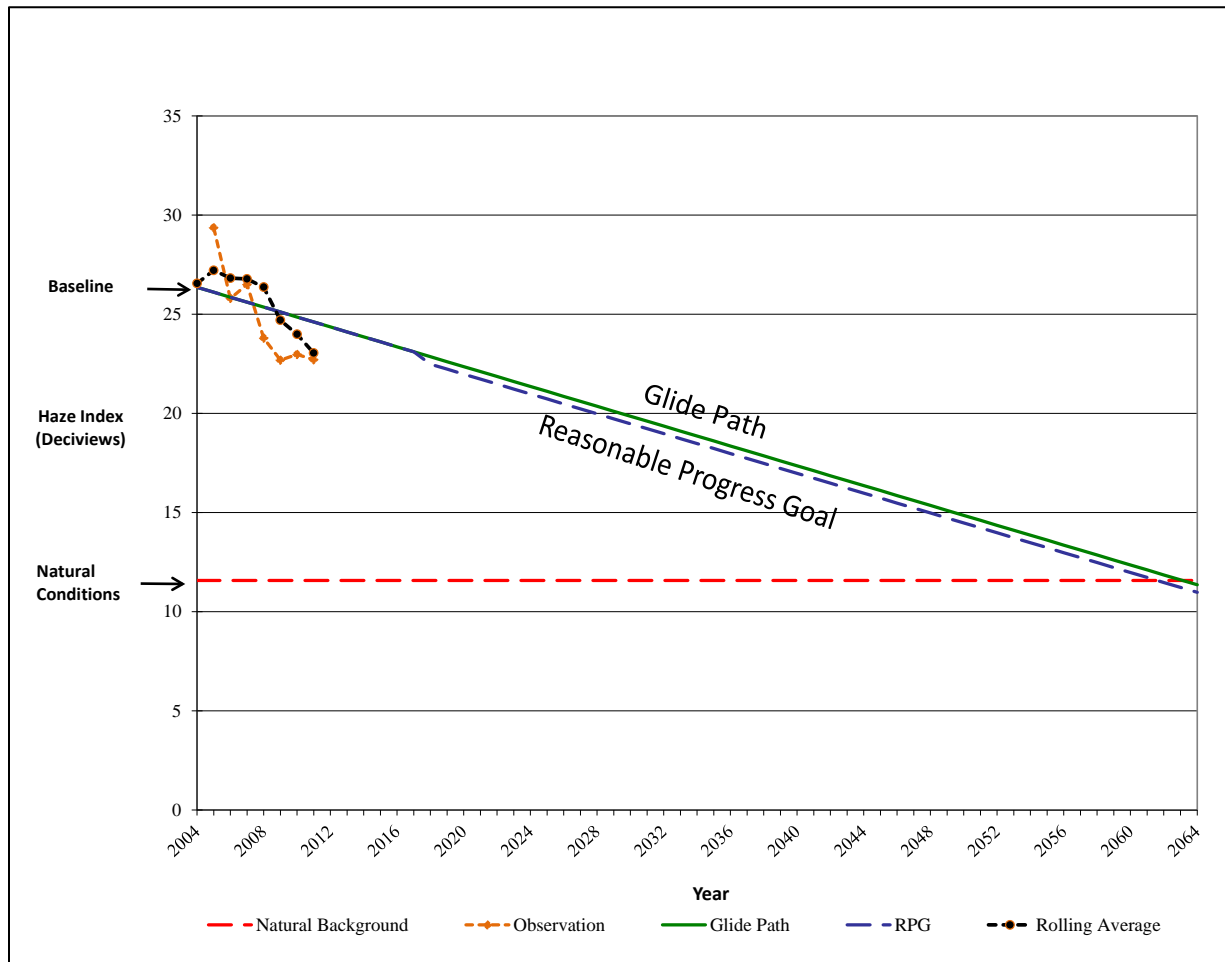

⁷¹ *Id.*

⁷² *Id.*

Figure 1 Reasonable Progress Assessment Upper Buffalo Wilderness Area, Arkansas 20% Worst Days

**Figure 2 Reasonable Progress Assessment Caney Creek
Wilderness Area, Arkansas: 20% Worst Days**

Despite Arkansas being on schedule to meet or beat the trajectory needed to achieve background visibility conditions by 2064, EPA is proposing more stringent RPGs that would require unnecessary additional controls. Specifically, EPA is requiring additional controls on Entergy Independence Units 1 and 2.⁷³ EPA’s proposed RPGs are more aggressive, which is inconsistent with EPA’s approach in certain other states that allow RPGs that would improve visibility over a much longer timeframe.⁷⁴

⁷³ 80 FR 18944 at 18992.

⁷⁴ 80 FR 18944 at 18997. (“These RPG’s reflect rates of progress that are faster than the rates projected by Arkansas.”)

EPA has proposed or accepted RPGs for other states that would allow those states to meet background visibility conditions well into the next century. In Texas, EPA proposed RPGs that would allow that state to achieve natural visibility conditions for the 20% worst days in Big Bend Wilderness Area in 194 years and in the Guadalupe Mountains in 159 years.⁷⁵ In Oklahoma, EPA proposed a 2018 RPG for the 20% worst days that put that state on track to attain natural visibility in the Wichita Mountains in 92 years.⁷⁶ For Arkansas, EPA has required RPGs that would be even more stringent than those needed to reach background visibility conditions in 49 years, which is the program's target.

In states farther geographically removed from Arkansas, EPA's treatment disparity becomes even more profound. In California, EPA approved that state's RPGs even though many of its Class I areas would not reach natural background conditions until well into the 2100's and beyond. For example, California's RPGs will not achieve background conditions in Desolation Wilderness Area until 2307, in Yosemite National Park until 2160, and in Ansel Adams Wilderness Area until 2200.⁷⁷

There is no justification for EPA arbitrarily setting RPGs that are stricter than those proposed by Arkansas and include controls on Entergy's Independence Plant. EPA's dramatically disparate approach to Arkansas's RPGs in comparison to other states is unreasonable and unnecessary to achieve "reasonable progress" towards reaching background conditions. EPA should withdraw the Proposed FIP and any subsequent plan should contain goals that are reasonable in light of EPA's treatment of other states.

⁷⁵ 79 FR 74853 at 74887.

⁷⁶ *Id.*

⁷⁷ Approval and Promulgation of Air Quality Implementation Plans; State of California; Regional Haze State Implementation Plan and Interstate Transport Plan; Interference With Visibility Requirement, 76 FR 13944, at 13951.

EPA arbitrarily chose the options for emissions control for Entergy Independence Units One and Two.

EPA arbitrarily chose the two options it presented for emissions controls at Entergy Independence Units One and Two as evidenced by EPA's failure to discuss a third option, which EPA presented to ADEQ for consideration prior to the promulgation of the Proposed FIP.⁷⁸ ADEQ received a technical support document dated February 11, 2015 within which EPA Region 6 presented three options for Entergy Independence: "Option 1: Propose No Additional Controls under Reasonable Progress"; "Option 2: Propose Only SO₂ Controls under Reasonable Progress"; and "Option 3: propose Both SO₂ and NO_x Controls Under Reasonable Progress."⁷⁹

Although ADEQ received this document on February 12, 2015, EPA never included it in the Rulemaking Docket.⁸⁰ When EPA published the Proposed FIP on April 8, 2015, the option to "Propose No Additional Controls under Reasonable Progress" had been inexplicably removed as an option from the proposed Regional Haze FIP. EPA completely excluded this option from consideration and no mention of it was made in the Proposed FIP.

While EPA has considerable discretion interpreting its own regulations, the law requires EPA to "cogently explain why it has exercised its discretion in a given manner."⁸¹ Whether or not EPA ultimately chose to reject the option, it is legally obligated to consider and explain its decision to or not to include it. The decision to provide ADEQ with a certain set of options prior to promulgation of the Proposed FIP and simply excise one of those options from the Proposed FIP without due consideration is arbitrary and capricious. EPA should withdraw the Proposed

FIP and any subsequent plan that might include emissions controls for Entergy Independence Units One and Two should include a proper consideration of the available options.

EPA failed to include the substantial contributions of Federal Land Managers to regional haze in the State’s Class I Areas from within the Class II Areas themselves.

As set forth in 40 C.F.R. § 51.308(i), the Regional Haze Rule requires states such as Arkansas to coordinate in various ways with Federal Land Managers. For example, states are required to provide Federal Land Managers with notice of the identified visibility impairment and an opportunity for consultation.⁸² However, despite EPA requiring this coordination, the actions of the Land Managers themselves are responsible for a disproportionate and unmeasured impact on the visibility of Arkansas’s Class I areas. States such as Arkansas are required to identify the impairment and elements for inclusion in the visibility monitoring strategy.

In 2007, the Arkansas Forestry Commission approved a Smoke Management Program that was developed, among other reasons, as a means of assuring that land managers throughout the State use specific techniques designed to ensure that burns conducted for the purpose of forest management (prescribed burns) do not interfere with air quality management goals. Prescribed burning is widely recognized as a wildfire prevention technique and is also used to revitalize forest ecosystems. When properly conducted, prescribed burning is a useful technique for various forest management purposes.

A Federal Land Manager is “the Secretary of the department with authority over the Class I areas.”⁸³ While several state agencies and private-sector entities practice prescribed burning, the United States Forest Service (“USFS”) is the largest practitioner. The USFS uses prescribed burns from within the very Class I areas that are meant to be protected by the

⁸² 40 C.F.R. § 51.308 (i).

⁸³ 40 C.F.R. § 51.301

Regional Haze Rule. For example, in 2006 the USFS was responsible for as much as 60% of the 30,000 acres of prescribed burns that were reported in the State.⁸⁴ In 2011, federal agencies were responsible for most of the burns that were conducted in violation of the procedures described in the State's Smoke Management Plan in which voluntary participants including the USFS agree to meet certain air-quality related criteria before initiating prescribed burns.⁸⁵ Most of burns conducted by federal agencies such as the USFS in Arkansas were conducted within the boundaries of designated National Forests.⁸⁶

There is currently no accepted regulatory procedure for isolating the visibility impacts of prescribed burning from other anthropogenic sources of haze. However, prescribed burns continue to be a significant source of the haze in the Class I areas that are meant to be protected by the Regional Haze program. As a result, the actions of Federal Land Managers practicing prescribed burning should be given due consideration. Therefore, EPA should withdraw the Proposed FIP, and any subsequent plan should include consideration of the substantial impacts of Federal Land Managers to haze conditions.

EPA has failed to comply with additional requirements under Executive Order 12866 and Executive Order 13211, and EPA should withdraw the proposed FIP until such time as it complies with those orders.

EPA asserts that its Proposed FIP is not a “significant regulatory action” within the meaning of Executive Order 12866 (“E.O. 12866”).⁸⁷ However, the proposed FIP would result in substantial and material costs being transferred onto Arkansas communities through increased electricity rates due to the installation of costly control equipment at affected EGUs. This is a

⁸⁴ Dr. Lynne C. Thompson, Presentation to the Arkansas Prescribed Fire Council (May 18, 2015) attached as Exhibit 3.

⁸⁵ Exhibit 3.

⁸⁶ *Id.*

⁸⁷ 80 FR 18944 at 19000.

material adverse effect, which renders the Proposed FIP subject to the requirements of E.O. 12866. EPA has not complied with the requirements of E.O. 12866, and the Proposed FIP should be withdrawn until such time as requirements of this executive order have been met.

Under E.O. 12866, a “significant regulatory action” is subject to certain review requirements by the Office of Information and Regulatory Affairs (“OIRA”), which is a subdivision the Office of Management & Budget (“OMB”).⁸⁸ For each significant regulatory action under E.O. 12866, OIRA must be provided with a copy of the draft regulation, together with a reasonably detailed description of the need for the regulatory action, and an explanation of how that action will meet that need.⁸⁹ In addition, the relevant agency must provide OIRA with an assessment of the costs and benefits of the regulatory action as well as the costs and benefits of reasonably feasible alternatives for each significant regulatory action.⁹⁰ By issuance of E.O. 13563 on January 18, 2011, the sitting President reaffirmed “the principles, structures, and definitions governing contemporary regulatory review that were established in Executive Order 12866 of September 30, 1993, were re-affirmed.”⁹¹

In this instance, EPA’s Proposed FIP falls within the definition of significant regulatory action as set out in E.O. 12866 and reaffirmed in E.O. 13563. A “Significant regulatory action” means any regulatory action that is likely to result in a rule that may: (1) Have an annual effect on the economy of \$100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or tribal governments or communities; (2) create a serious inconsistency or otherwise interfere with an action taken or planned by another agency; (3) materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations

⁸⁹ *Id.* at Sec. 6(a)(1)(B)

⁹⁰ Exec. Order No. 12866, 58 FR 51735, Sec. 6(c), (Sept. 30, 1993).

⁹¹ Exec. Order No. 13563, 76 FR 3821, (Jan. 18, 2011)

of recipients thereof; or (4) raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in this Executive Order.⁹²

The Proposed FIP would adversely affect in a material way Arkansas communities by causing increased electricity rates that would be passed on to Arkansas consumers. Specifically, the following facilities owned by electric utilities engaged in interstate commerce were determined to be subject-to-BART or otherwise required to install emissions controls: the Arkansas Electric Cooperative (“AECC”) Carl E. Bailey Generating Station; the AECC John L. McClellan Generating Station; the American Electric Power (“AEP”) Flint Creek Power Plant; the Entergy White Bluff Plant; the Entergy Lake Catherine Plant; and the Entergy Independence Plant.

These facilities are operated by public utilities with the ability to shift the costs of these controls from the utilities to the consumers of the electricity generated by these plants and generators. Under Arkansas law, a public utility such as those operating the aforementioned plants, may petition to the Arkansas Public Service Commission to recover costs for emissions control costs through a surcharge for those expenses so long as specific statutory elements have been met.⁹³ This statute specifically provides for the recovery of costs that “[r]elate to the protection of the public health, safety of the environment” so long as other elements have been met.⁹⁴ That surcharge would allow the affected utilities to transfer costs of compliance with the Proposed FIP onto Arkansas ratepayers. These costs would place a substantial burden on Arkansas communities. This burden constitutes a material adverse impact that renders this action subject to requirements of E.O. 12866.

⁹² *Id.* at Sec.3(f).

⁹³ Ark. Code Ann. § 23-4-501.

⁹⁴ Ark. Code Ann. § 23-4-501(a)(1)(E).

In addition, a significant regulatory action under E.O. 12866 is considered a “significant energy action” and subject to yet further review by OIRA under E.O. 13211 if that action is also ‘likely to have a significant adverse impact on the supply, distribution, or use of energy.’⁹⁵ The Proposed FIP will likely have a significant adverse impact on use of energy through decreased use by electricity consumers responding to increased rates as a result of the emissions controls required. As a result of this adverse impact, the Proposed FIP is a “significant energy action.” In order to comply with E.O. 13211, EPA is required to submit to OIRA a “Statement of Energy Effects,” which describes the effects of certain regulatory actions on energy supply, distribution, or use.⁹⁶

ADEQ disagrees with EPA that the Proposed FIP is not subject to E.O. 13211 and E.O. 12866. The impacts of the Proposed FIP render it subject to both executive orders, and ADEQ is troubled that the EPA has not provided OIRA with the statements and other information required to comply with those orders. ADEQ is greatly concerned that EPA has not provided OIRA with the cost-benefit analysis required by E.O. 12866. This is a particular concern because EPA failed to perform a proper analysis of the costs of meeting EPA’s proposed RPGs.

As a result of EPA’s failure to analyze the “cost of compliance” factor in relation to the RPGs,⁹⁷ EPA has not performed any analysis of the costs of the overall impact of the Proposed FIP. Without EPA complying with the required additional review by OIRA, there would be no oversight of the costs of the Proposed FIP at all. Given the recent concerns by the Supreme Court in *Michigan v. EPA* about the rationality of imposing billions of dollars in economic costs in return for a few dollars in health or environmental benefits,⁹⁸ EPA should strictly comply with

⁹⁵ Exec. Order No. 13211, 66 FR 28355, (May 18, 2001).

⁹⁸ *Michigan v. E.P.A.*, No. 14-46, 2015 WL 2473453, at *7 (U.S. June 29, 2015) (“[o]ne would not say that it is even rational, never mind ‘appropriate,’ to impose billions of dollars in economic costs in return for a few dollars in health or environmental benefits.”).

E.O. 12866 and 13211 in order to properly determine the extent of the impacts of the Proposed FIP on the state of Arkansas. Since EPA has failed to do so, ADEQ requests that EPA withdraw the Proposed FIP.⁹⁹

ADEQ reserves its right to comment on whether EPA properly made a BART determination for Arkansas facilities, including the Domtar-Ashdown Mill, in light of the Ninth Circuit's recent opinion in *Nat'l Parks Conservation Ass'n v. E.P.A.*

In determining what specific controls are BART, EPA is required to take into consideration a number of factors including “the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.”¹⁰⁰ In *Nat'l Parks Conservation Ass'n v. E.P.A.*, PPL Montana, a part-owner of a coal-fired power plant, objected to EPA's use of the CALPUFF visibility model in determining BART for two units at one of its coal-fired power plants.¹⁰¹

The basis of PPL Montana's objection was that the maximum potential incremental visibility benefit of emissions control technology chosen by EPA fell within the model's margin of error, meaning such improvement cannot be “reasonably ... anticipated” as required by the Act.¹⁰² The Ninth Circuit Court of Appeals recently held that EPA had not “considered the relevant factors and articulated a rational connection between the facts found and the choice made.”¹⁰³ As a result, EPA acted in an arbitrary and capricious manner by failing to provide an adequate explanation as to how the degree of visibility improvement could be reasonably anticipated.¹⁰⁴

⁹⁹ Ark. Code Ann. § 23-2-304.

¹⁰⁰ 42 U.S.C.A. § 7491.

¹⁰¹ See generally, *Nat'l Parks Conservation Ass'n v. E.P.A.*, No. 12-73710, 2015 WL 3559149, at *13 (9th Cir. June 9, 2015).

¹⁰² See 42 U.S.C. § 7491(g)(2); *Nat'l Parks Conservation Ass'n v. E.P.A.*, No. 12-73710, 2015 WL 3559149, at *8 (9th Cir. June 9, 2015).

¹⁰³ *Nat'l Parks Conservation Ass'n v. E.P.A.*, No. 12-73710, 2015 WL 3559149, at *13 (9th Cir. June 9, 2015).

¹⁰⁴ *Id.*

At least one facility affected by the Proposed FIP has conducted an analysis to determine whether or not the maximum potential incremental visibility benefit of emissions control technology chosen by EPA fell within the margin of error. Specifically, ADEQ is aware that Domtar is currently performing modeling to determine whether or not predicted visibility improvements fell within the margin of error at its Ashdown Mill.¹⁰⁵ Other facilities are likely performing modeling to make similar determinations. Accordingly, ADEQ reserves the right to comment on this issue until such time as Arkansas's facilities have had adequate time to make those determinations.

As the D.C. Circuit explained in vacating a portion of the Regional Haze Rule itself, it is arbitrary and capricious for EPA to force an emissions source "to spend millions of dollars for new technology that will have no appreciable effect on the haze in any Class I area."¹⁰⁶ In its Proposed Rule, EPA dictates the imposition of control equipment for emissions reduction under BART in instances where CALPUFF predicted minor visibility improvements. EPA did so without first undertaking any site specific analytical analysis to determine if the visibility improvements were in fact within the CALPUFF margin of error.

Specifically, it appears from the Proposed FIP that the highest modeled visibility improvement after EPA's BART determinations for any of the three Arkansas EGUs at any Class I area is 0.813 deciviews attributed to SO₂ controls at the Entergy White Bluff Unit I at Caney Creek, which is below the 1 deciview threshold of visibility perception. Furthermore, EPA required the installation of low-NO_x burners and over fire air at SWEPCO's Flint Creek Unit, even though the highest modeled visibility improvement was 0.081 deciviews for NO_x. Given the acknowledged over-prediction of the CALPUFF model and its inaccuracy at these low

¹⁰⁵ Letter from Annabeth Reitter, Corporate Manager, Domtar, to Guy Donaldson, Chair of the Air Planning Section, E.P.A., (July 6, 2015) attached as Exhibit 4.

¹⁰⁶ *Nat'l Parks Conservation Ass'n v. E.P.A.*, No. 12-73710, 2015 WL 3559149, at *10 (9th Cir. June 9, 2015)(citing *Am. Corn Growers Ass'n v. EPA*, 291 F.3d 1, 7 (D.C.Cir.2002))

levels, the actual visibility impact for the State's EGUs (and most likely the other subject-to-BART sources as well) would be much lower.

The CAA does not require visibility improvements that cannot be reasonably anticipated. Conversely, visibility improvements that are less than the margin of error were expressly found to be invalid. Until such time as EPA can provide assurance that the CALPUFF model is a reliable indicator of visibility projections, many of the numerical projections contained in the Proposed FIP are themselves, unreliable. For this reason, the Proposed FIP is flawed and is overly expansive and should be withdrawn.

Conclusion

Consideration of the comments above should make it apparent that the Proposed FIP is not a viable option for implementation of the Regional Haze program in Arkansas. The Proposed FIP contains misleading cumulative visibility metrics. EPA arbitrarily requires sources that are subject to the CSAPR Rule to also control NO_x emissions as BART. EPA improperly performed the reasonable progress analysis required by the Regional Haze Rule, which resulted in requiring unneeded emissions controls for the Entergy Independence Plant. EPA also chose to forego CAMx photochemical modelling such as that used in Texas in favor of a less accurate algorithm that resulted in inferior RPGs. In addition, EPA has not complied with E.O 12866 and E.O. 13211.

EPA should withdraw the Proposed FIP, and any subsequent plan should address the issues presented in this letter. While ADEQ will continue to work to develop an acceptable SIP for approval by EPA, the harsh deadline of December 15, 2015 proposed in a recently proposed consent decree between EPA and Sierra Club may stifle those efforts. Nonetheless, ADEQ will diligently continue to work towards the resolution of all of the issues raised during the public comment period.

STATE OF ARKANSAS
ASA HUTCHINSON
GOVERNOR

June 2, 2015

Mr. Ron Curry
Regional Administrator
U.S. Environmental Protection Agency, Region VI
1445 Ross Avenue, Suite 1200
Dallas, TX 75202-2733

Dear Regional Administrator Curry:

In accordance with the provisions of 40 C.F.R. § 51.308, this letter and enclosures constitute the submittal of the Arkansas State Implementation Plan (SIP) for the Regional Haze five-year review. The enclosed documents are intended to address the requirements of 40 C.F.R. § 51.308(g) requiring periodic reports evaluating progress towards the Reasonable Progress Goals established for mandatory Class I areas where visibility may be impacted by Arkansas sources.

The Arkansas Regional Haze SIP was submitted on July 29, 2008. The enclosed SIP submittal addresses actions the Arkansas Department of Environmental Quality (ADEQ) has taken to fulfill the requirements under 40 C.F.R. § 51.308(g) for periodic progress reports. In accordance with 40 C.F.R. § 51.308(h)(1), the State is submitting a "Negative Declaration" that further revision of the existing implementation plan is not needed at this time. However, ADEQ is cognizant of its obligation and the associated timeframe to address the disapproved components of the 2008 Arkansas Regional Haze SIP submittal.

The Regional Haze five-year review SIP was provided to Federal Land Managers on April 21, 2014. The notice of public hearing and comment period was published in a statewide newspaper on January 2, 2015 and a link to the SIP submittal was posted on the ADEQ website with details regarding the public comment period on January 2,

2015. A public hearing was held on February 2, 2015, at the ADEQ headquarters in North Little Rock, Arkansas. The public comment period ended on February 17, 2015. Responses to public comments are contained in Appendix F: Compilation of Public Comments and Response to Comments within the enclosed SIP submittal.

Arkansas respectfully requests timely review and approval of the enclosed documents as an element of the official Regional Haze program for the State. If you have any questions regarding information contained herein, please contact Stuart Spencer, Legal Policy Advisor, ADEQ, by electronic mail at spencer@adeq.state.ar.us, or by phone at 501-682-6347.

Sincerely,

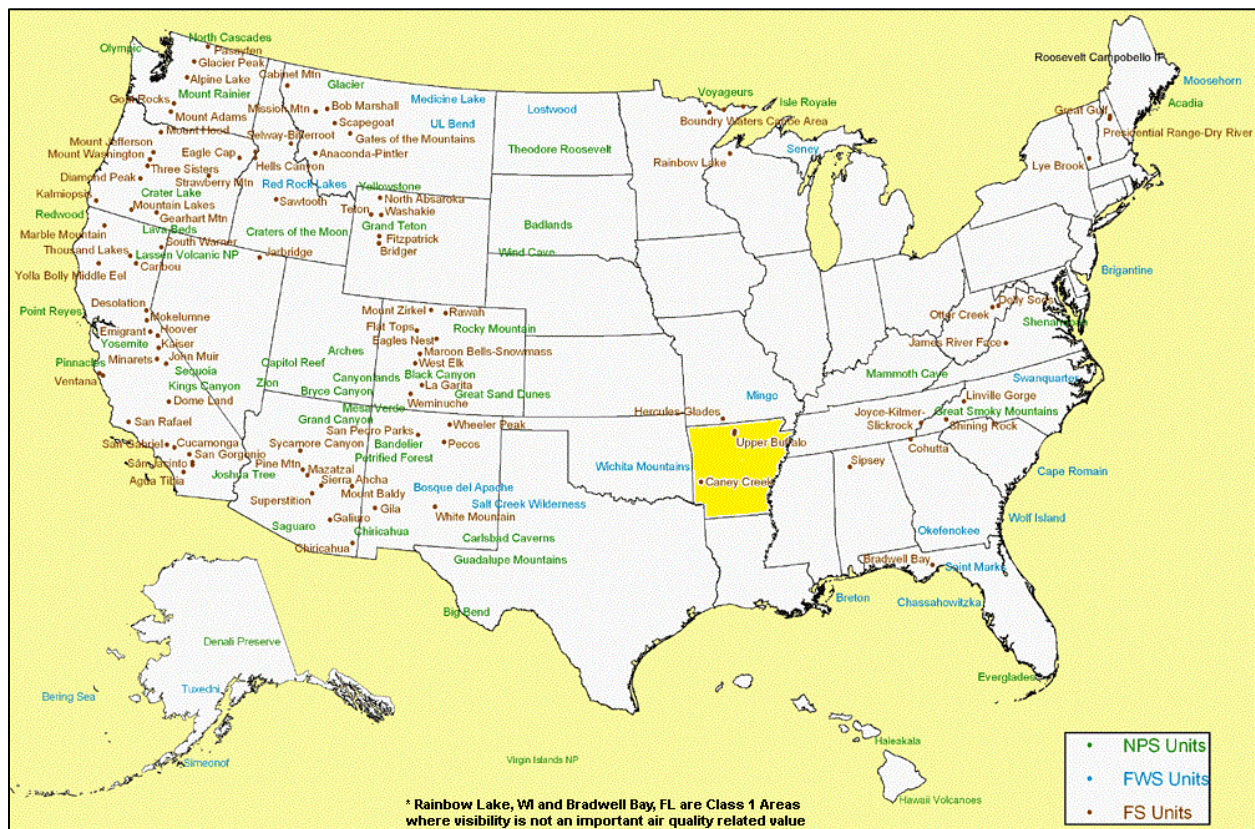

Asa Hutchinson

Enclosure: Arkansas State Implementation Plan for the Regional Haze Five-Year Review

Executive Summary

Congress added the national goal of preventing any future and remedying any existing impairment of visibility at mandatory Class I Federal areas in the 1977 Clean Air Act (C.A.A.) Amendments. The Regional Haze Rule (RHR) was promulgated in July 1999 (64 Fed. Reg. 35714, July 1, 1999) to further Congress's national goal, and established regulations to eliminate man-made visibility impairment in Class I areas by 2064. Nationally, there are 156 mandatory Class I Federal areas (Class I areas). There are two Class I areas in Arkansas: Upper Buffalo and Caney Creek Wilderness areas. See Figure 1.

Figure 1. Mandatory Class I Areas

Regional haze is a form of visibility impairment not directly attributable to a single source but occurs as a result of emissions of air pollutants from numerous sources located over a wide geographic area. The RHR and related regulations (40 C.F.R. § 51.308 and Appendix Y to Part 51) contain provisions that encouraged state, local, and tribal agencies to work cooperatively within regional planning organizations (RPOs) to address visibility impairment. Five RPOs were created for this purpose. Arkansas was part of the Central Regional Air Planning Association (CENRAP), originally comprised of nine states in the central U.S.

In accordance with the requirements of 40 C.F.R. § 51.308, the State of Arkansas submitted its Regional Haze SIP to EPA on September 23, 2008. On March 12, 2012, EPA took action and partially approved and partially disapproved the Arkansas Regional Haze SIP (2008 Arkansas Regional Haze SIP), as published in the Final Rule “*Approval and Promulgation of Implementation Plans; Arkansas; Regional Haze State Implementation Plan; Interstate Transport State Implementation Plan To Address Pollution Affecting Visibility and Regional Haze*” (77 Fed. Reg. 14604). The following is a brief summary of EPA’s decision:

Approved: Certain core elements

- Identification of affected Class I areas;
- Determination of baseline and natural visibility conditions;
- Determination of Uniform Rate of Progress (URP);
- Reasonable progress goal (RPG) consultation and long-term strategy (LTS) consultation;
- Coordination of Regional Haze and reasonably attributable visibility impairment (RAVI);
- Regional haze monitoring strategy and other SIP requirements under 40 C.F.R. § 51.308(d)(4);
- Commitment to submit periodic regional haze SIP revisions and periodic progress reports describing progress towards RPGs;
- Commitment to make a determination of the adequacy of the existing SIP at the time a progress report is submitted; and
- Consultation and coordination with Federal Land Managers (FLMs).

Partially approved and partially disapproved:

- Approved Arkansas’s identification of sources found in the Arkansas Pollution Control and Ecology Commission (APC&EC), Regulation of the Arkansas Plan of Implementation for Air Pollution Control, Regulation No. 19, Chapter 15 that are best available retrofit technology (BART) eligible, with the exception of 6A Boiler at the Georgia-Pacific Crossett Mill, which EPA found to be BART-eligible.
- Approved Arkansas’s identification of subject-to-BART sources, with the exception of the 6A and 9A Boilers at Georgia-Pacific Crossett Mill, which EPA found to be subject-to-BART.
- Approved portions of the BART compliance provision that require each Arkansas subject-to-BART source to install and operate BART as expeditiously as practicable, but within five years of approval of Arkansas Regional Haze SIP by EPA. Arkansas’s inclusion of the compliance provision that would require Arkansas subject-to-BART sources to install and operate BART no later than six years after the effective date of the State’s regulation (if such date takes place before five years from EPA approval of the Arkansas Regional Haze SIP) is not a required element of the Regional Haze SIP, pursuant to Section 169 of the C.A.A., and therefore was disapproved.

- Partially disapproved Arkansas’s submitted LTS because it relies on portions of the Arkansas Regional Haze SIP that EPA disapproved, including some of Arkansas’s BART emission limits. In addition, Arkansas did not show that the strategy will adequately achieve the RPGs set by Arkansas and by other nearby states.

Disapproved:

- Arkansas’s RPGs required under 40 C.F.R. § 51.308(d)(1);
- Arkansas’s sulfur dioxide (SO₂), nitrogen oxides (NO_x) and particulate matter (PM) BART determinations; and
- Portion of the BART compliance provision found in APC&EC Reg. 19.1504(B), which requires each source subject-to-BART to install and operate BART no later than six years after the effective date of the Arkansas RHR (found in APC&EC Regulation No. 19) for the Regional Haze SIP.

The Regional Haze Program has been the subject of litigation, making it difficult to determine what control measures could be included in SIPs and, consequently, to complete the SIPs in a timely manner. The litigation includes the following.

On May 24, 2002, the U.S. Court of Appeals for the District of Columbia (D.C.) Circuit issued a ruling vacating the RHR in part and sustaining it in part, based on a finding that EPA’s prescribed methods for determining BART were inconsistent with the C.A.A. (*American Corn Growers Assn. v. EPA*, 291 F.3d 1 (D.C. Cir. 2002)).

On February 18, 2005, the D.C. Circuit decided another case dealing with BART and a BART alternative program, *Center for Energy and Economic Development v. EPA*, No. 03–1222, (D.C. Cir. Feb. 18, 2005) (“*CEED*”). *CEED* affirmed EPA’s interpretation of C.A.A. 169A(b)(2) as allowing for non-BART alternatives where those alternatives make greater progress than BART. EPA promulgated a rule on July 6, 2005, entitled “Regional Haze Regulations and Guidelines for Best Available Retrofit Technology (BART) Determinations” (“the BART Rule”) (70 Fed. Reg. 39104) to assist states in identifying which of their BART-eligible sources should undergo a BART analysis (i.e., which are “sources subject-to-BART”) and selecting appropriate controls (“the BART determination”).

Around the same time, EPA issued the Clean Air Interstate Rule (CAIR) on May 12, 2005, (70 Fed. Reg. 25162), which states could implement in lieu of BART. The rule affected 28 states and the District of Columbia and included a cap and trade program targeting SO₂ and NO_x. In July 2008, the Court found CAIR and EPA’s CAIR Federal Implementation Plans (FIPs) unlawful (*North Carolina v. EPA*, 531 F.3d 896 (D.C. Cir. 2008)), modified on rehearing (*North Carolina v. EPA*, 550 F.3d 1176, 1178 (D.C. Cir. 2008)). The ruling remanded CAIR to the EPA, leaving existing CAIR programs in place while directing EPA to replace them as rapidly as possible with a new rule consistent with the C.A.A.

EPA proposed a new rule, the Cross-State Air Pollution Rule (CSAPR), on July 6, 2010. The Program applied to 31 states and the District of Columbia to improve air quality significantly by reducing power plant emissions that contribute to ozone and fine particle emissions in other states, particularly SO₂ and NO_x emissions. Some states were included for ozone season (via NO_x reductions) or PM_{2.5} (via SO₂ and NO_x reductions) or both ozone and PM_{2.5}. EPA quantified in this rule the ozone season NO_x emission reductions that are necessary—but may not be sufficient—to eliminate all significant contribution to nonattainment and interference with maintenance in other states. Arkansas is included as one of the states that significantly contribute to nonattainment or interfere with maintenance of (the 1997 Ozone) National Ambient Air Quality Standard (NAAQS) downwind in the final CSAPR.

The final rule on CSAPR was published on August 8, 2011 (76 Fed. Reg. 48208). To make technical adjustments to the CSAPR based on new information, EPA proposed a rule revision on October 6, 2011. The CSAPR was scheduled to replace CAIR starting January 1, 2012. However, on December 30, 2011, the U.S. Court of Appeals for the D.C. Circuit issued a ruling that vacated the CSAPR and reinstated the CAIR program.

On October 5, 2012, EPA filed a petition for rehearing of the Court's decision on CSAPR. On November 19, 2012, EPA sent a Memo to Regions: Next Steps for Pending Redesignation Requests and State Implementation Plan Actions Affected by the Recent Court Decision Vacating the 2011 CSAPR. On January 24, 2013, the U.S. Court of Appeals declined the rehearing petition. On March 29, 2013, EPA petitioned the U.S. Supreme Court to review the judgment of the U.S. Court Appeals on CSAPR. On June 24, 2013, the U.S. Supreme Court granted EPA's petition.

On April 29, 2014, the Supreme Court reversed the D.C. Circuit opinion on CSAPR. On June 26, 2014, EPA filed a motion in the U.S. Court of Appeals for the D.C. Circuit to lift the stay of CSAPR. While the Court considered the motion, CAIR remained in effect. EPA's request for a three-year delay in the compliance deadlines would make the Phase 1 emissions budgets applicable in 2015 and 2016 (versus 2012 and 2013) and the Phase 2 emissions budgets applicable in 2017 and beyond (versus 2014 and beyond).

On October 23, 2014, the U.S. Court of Appeals for the D.C. Circuit ordered that EPA's motion to lift the stay of the CSAPR be granted. CSAPR Phase 1 implementation went into effect in 2015 with Phase 2 beginning in 2017. As of May 1, 2015, states are required to implement the requirements of CSAPR.

On April 8, 2015, EPA issued a proposed Federal Implementation Plan (FIP) for Arkansas (Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Proposed Rule – 80 Fed. Reg.

18944, April 8, 2015) and solicited comments on the approach to Regional Haze implementation described therein. ADEQ is evaluating the proposed FIP.

Chapter 1: Introduction to the Federal Regional Haze Program Requirements

1. Background

In amendments to the C.A.A. in 1977, Congress added Section 169 (42 U.S.C. § 7491) setting forth the following national visibility goal of restoring pristine conditions in national parks and Wilderness areas:

“Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Class I Federal areas which impairment results from man-made air pollution.”

When the C.A.A. was amended in 1990, Congress added Section 169B (42 U.S.C. § 7492), authorizing further research and regular assessments of the progress made so far. In 1993, the National Academy of Sciences concluded that “current scientific knowledge is adequate and control technologies are available for taking regulatory action to improve and protect visibility.”

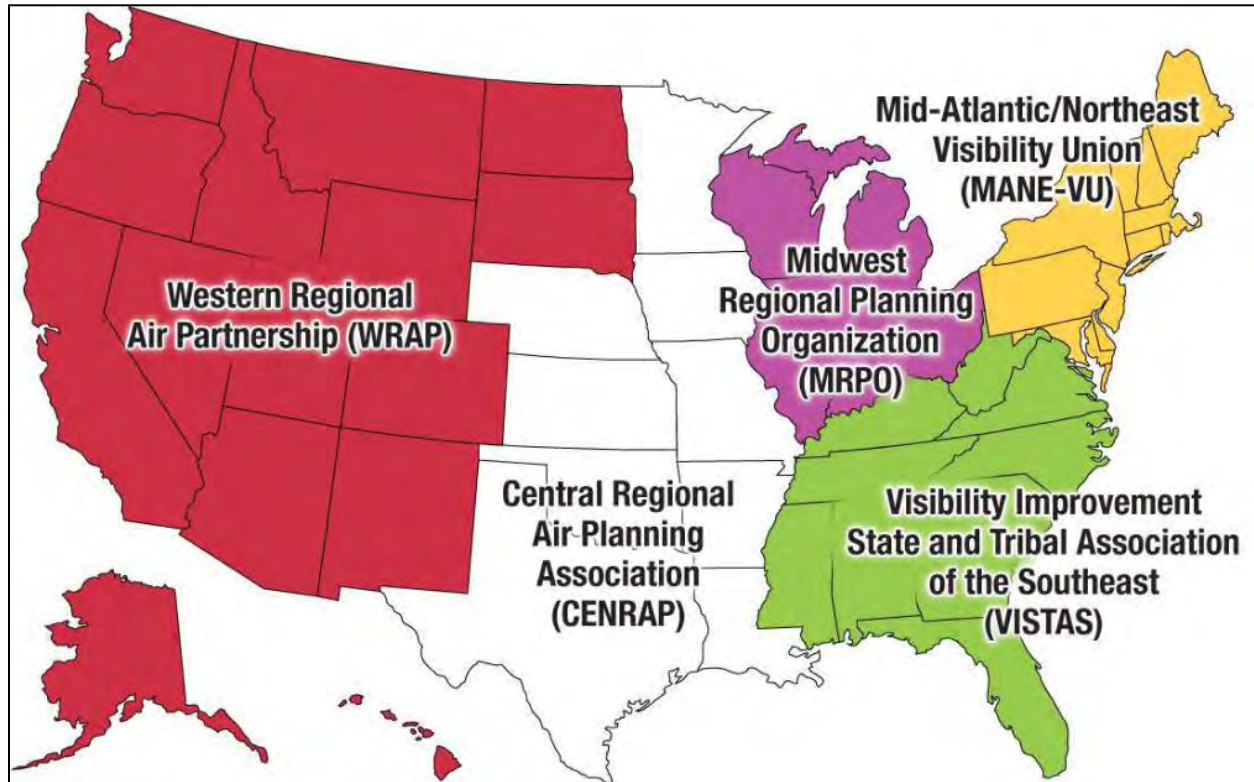

In addition to authorizing creation of visibility transport commissions and setting forth their duties, Section 169B(f) of the C.A.A. specifically mandated creation of the Grand Canyon Visibility Transport Commission (GCVTC) to make recommendations to the EPA for the region affecting the visibility of the Grand Canyon National Park. In June 1996, following four years of research and policy development, the GCVTC submitted its report to EPA. This report, as well as the many research reports prepared by GCVTC, contributed invaluable information to EPA in its development of the federal regional haze rule.

EPA’s RHR was adopted July 1, 1999, (64 Fed. Reg. 35714) and aims to reach natural background conditions by 2064. This rulemaking addressed the combined visibility effects of various pollution sources over a wide geographic region. EPA concluded that this meant that many states—even those without Class I areas—would be required to participate in haze reduction efforts.

2. Regional Planning

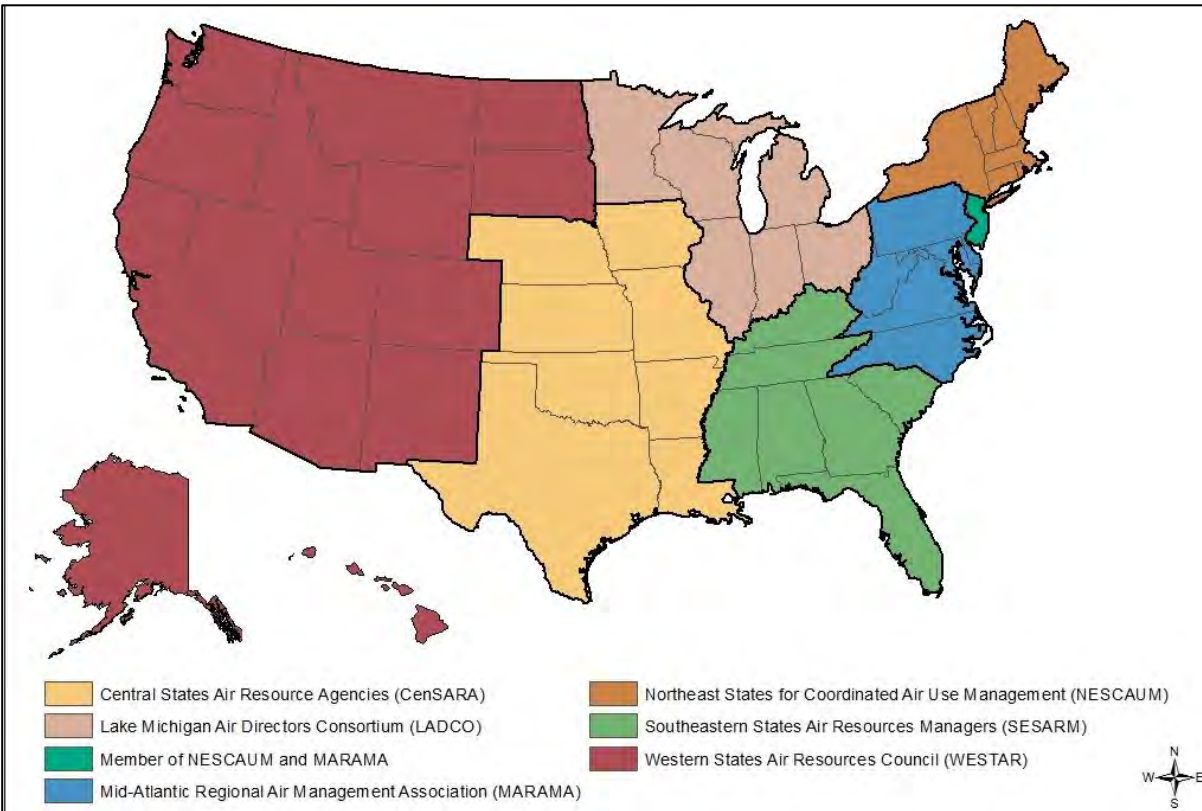

EPA designated five RPOs to assist with the coordination and cooperation needed to address the visibility issues that states in the five regions share or have in common. Those states that make up the midsection of the contiguous United States were designated as the Central Regional Air Planning Association (CENRAP). CENRAP subsequently ceased to function and Arkansas is communicating through the Central States Air Resource Agencies (CenSARA) with the other states that were part of CENRAP . Figure 1.1 is a map depicting the five RPO regions.

Figure 1.1. Regional Planning Organizations

Using federal funds available to them, the RPOs developed a wide array of technical products for their member and non-member states, including updated emissions inventories, additional monitoring to help answer questions related to visibility impacts, and modeling to help determine which pollutants should be the focus for control measures. The RPOs were also key to coordination and consultation efforts among states, tribes, federal land managers, and EPA. The products and efforts of the RPOs culminated in the SIPs submitted to EPA. RPO funding ceased in 2011 and, currently, multi-jurisdictional organizations (MJOs), such as CenSARA, manage and coordinate multi-state air quality technical projects. Figure 1.2 is a map depicting the six MJO regions. Because of directed funding, tribes and FLMs are not members of MJOs, though communication and coordination is still an important component of regional haze work.

Figure 1.2. Multi-Jurisdictional Organizations

3. Requirements for Periodic Reports Describing Progress towards Reasonable Progress Goals

Pursuant to the requirements of 40 C.F.R. § 51.308(g), (h), and (i), Arkansas submits this Progress Report as a SIP revision. Arkansas has adopted this SIP revision in accordance with State laws and rules.

The requirements addressed in the following sections include the status of implementing committed control measures, summaries and analyses of emissions and monitoring changes, and assessments of impacts on Class I areas identified in the 2008 Arkansas Regional Haze SIP.

Per 40 C.F.R. § 51.308(g), this submittal also complies with 40 C.F.R. §§ 51.102 and 51.103 to offer the public the opportunity to request a hearing and/or comment on a proposed SIP revision and to submit the SIP revision to EPA. Arkansas provided public notice of the opportunity to comment on the SIP revision on January 2, 2015. Arkansas held a public hearing regarding the SIP revision on February 2, 2015. Public comments received were addressed and are summarized under Appendix F: Compilation of Public Comments and Response to Comments found within this report.

Chapter 2: Progress Report Elements—40 C.F.R. § 51.308(g)

1. Introduction

As stated in 40 C.F.R. § 51.308(g), the RHR, final rule published July 1, 1999, (64 Fed. Reg. 35714) requires states to submit progress reports five years following the submission of the 2008 Regional Haze SIP and every five years following submission of a comprehensive regional haze SIP revision. The general purpose of the five-year review is to evaluate progress towards the reasonable progress goals of each mandatory Class I area which may be affected by emissions from within the State. Arkansas has two Class I areas: Upper Buffalo and Caney Creek Wilderness areas. This document fulfills 40 C.F.R. § 51.308(g) requirements. This reasonable progress report evaluates the progress made towards RPG for Caney Creek and Upper Buffalo Class I areas, as well as each mandatory Class I area located outside Arkansas that may be affected by emissions from Arkansas sources.

As suggested by EPA¹, the following is a brief description of the overall nature of the visibility problem in the two Class I areas affected by the State. As shown in Figure 2.1 and Figure 2.2, ammonium sulfate is the largest contributor to visibility impairment at Upper Buffalo and Caney Creek Wilderness areas on the 20% worst days. As evidenced by Figure 2.3 and Table 2.1, EGUs are the largest emitter of SO₂. After ammonium sulfate, the next largest fraction of regional haze at these two Class I areas is organic carbon. In 2004, Drs. Tom Moore and Brooke Hemming² suggested if the ratio of organic carbon to elemental carbon (OC/EC) was seven or greater, this may be associated with vegetation fires. The OC/EC³ for the 20% worst days at Upper Buffalo and Caney Creek Wilderness area is 11. Therefore, the data seem to suggest the source of organic carbon at these two Class I areas was due to vegetation fires.

137	7,572	618	357	73,629	11,587

2. Status of Control Measures

40 C.F.R. § 51.308(g)(1) requires that the five-year periodic report contain: “A description of the status of implementation of all measures included in the implementation plan for achieving reasonable progress goals for mandatory Class I Federal areas both within and outside the State.”

The long-term strategy (LTS) developed for the 2008 Arkansas Regional Haze SIP was to include all measures relied upon by a state to achieve the reasonable progress goals of Class I areas affected by their emissions. Arkansas’s LTS was broad in scope to ensure it encompassed all ongoing state and federal programs reducing the types of air pollutants that might be associated with visibility impairment. Additional factors listed in 40 C.F.R. § 51.308(d)(3)(v)

⁴ Source: U.S. EPA, 2011 NEI version 1.

such as smoke management plans, source retirements and replacements, emissions limits, and the net effect upon visibility from projected changes in emissions from anthropogenic emissions over the period addressed by the long-term strategy, were also required components of the long-term strategy. Not all items included in Arkansas's LTS are expected to significantly influence visibility impairment in a Class I area but were included for completeness. A review of all applicable measures, either specifically identified by the 2008 Arkansas Regional Haze SIP or other measures of greatest relevance to the reasonable progress goals (RPGs) of the Arkansas Class I areas, is provided below.

i. Best Available Retrofit Technology

As stated in the Executive Summary, EPA partially approved and partially disapproved on March 12, 2012⁵, the 2008 Arkansas Regional Haze SIP. This rule partially approved and partially disapproved Arkansas's identification of BART-eligible sources and subject-to-BART sources; requirements for BART, Chapter 15 of the APC&EC Regulation No. 19, the LTS, and the RPG.

EPA disapproved Arkansas's BART determinations for the following sources:

- SO₂, NO_x, and PM for Arkansas Electric Cooperative Corporation (AECC) Bailey Plant Unit 1 and the AECC McClellan Plant Unit 1;
- SO₂ and NO_x for American Electric Power (AEP) Flint Creek Plant Boiler No. 1;
- NO_x for the natural gas firing scenario and the SO₂, NO_x, and PM for the fuel oil firing scenario for Entergy Lake Catherine Plant Unit 4;
- SO₂ and NO_x for both the bituminous and sub-bituminous coal firing scenarios for Entergy White Bluff Plant Units 1 and 2;
- BART determination for the Entergy White Bluff Plant Auxiliary Boiler;
- SO₂ and NO_x for Domtar Ashdown Mill Power Boiler No. 1; and
- SO₂, NO_x and PM for Domtar Ashdown Mill Power Boiler No. 2.

As a result of the disapproval of the aforementioned BART elements, ADEQ had a meeting with the subject-to-BART sources (listed above) to inform them of EPA's final decision. As a follow up, ADEQ sent certified return receipt letters dated May 14, 2012⁶, to the individual subject-to-BART sources informing them of ADEQ's decision to revise the SIP and comply with the statutory five-factor analysis requirements. This decision required the sources to prepare new BART-related analyses. Specifically, ADEQ requested the facilities to submit an analysis of the five factors specified in C.A.A. Section 169A(g)(2) for the affected subject-to-BART unit/units and pollutants. Each five-factor analysis was to be conducted in accordance with 40 C.F.R. Part 51, Appendix Y and the guidance provided by ADEQ. ADEQ has been working closely with the

⁵ 77 Fed. Reg. 14604 (2012).

⁶ See **Error! Reference source not found.**

sources through phone calls, meetings, and other correspondence. In addition, ADEQ and sources are working with EPA, Region 6, on their five-factor analyses. EPA is reviewing these analyses and providing comments. These comments are forwarded to the sources for response. At the time of this document development, ADEQ is unable to determine when revisions to the disapproved portions of the SIP will be submitted to EPA.

ii. Subject-to-BART Sources and Class I Areas Affected

BART determination modeling performed by the Department indicated there were six Arkansas facilities with subject-to-BART units whose emissions caused or contributed to visibility impairment at four Class I areas. However, EPA disapproved ADEQ’s BART exemption finding of Georgia-Pacific Paper’s 6A and 9A Boilers and found these units to be subject-to-BART. Table 2.2 lists the facilities, subject-to-BART units, and pollutants that were not approved. A short description of the facilities with subject-to-BART units and the Class I areas affected follows.

Table 2.2. Facilities with Subject-to-BART Units in the State of Arkansas

Facility Name	Unit ID - Description	BART Pollutants
American Electric Power - Flint Creek Plant	SN-01 - Boiler	SO ₂ , NO _x
AR Electric Cooperative - Bailey Generating Station	SN-01 - Boiler	SO ₂ , NO _x , PM
AR Electric Cooperative - John L. McClellan Generating Station	SN-01 - Boiler	SO ₂ , NO _x , PM
Entergy - Lake Catherine	SN-02 - Unit 4 Boiler Natural Gas Firing	NO _x
	SN-02 - Unit 4 Boiler Oil Firing	SO ₂ , NO _x , PM
Entergy - White Bluff	SN-01 - Unit 1 Bituminous and Sub-bituminous Coal Firing	SO ₂ , NO _x
	SN-02 - Unit 2 Bituminous and Sub-bituminous Coal Firing	SO ₂ , NO _x
	SN-05 - Auxiliary Boiler	
Domtar - Ashdown	SN-03 – No. 1 Power Boiler	SO ₂ , NO _x
	SN-05 – No. 2 Power Boiler	SO ₂ , NO _x , PM
Georgia-Pacific Paper - Crossett	6A Boiler	SO ₂ , NO _x , PM
	9A Boiler	SO ₂ , NO _x , PM

American Electric Power - Flint Creek Power Plant (Arkansas Facility Identification Number (AFIN) 04-00107)

is located in Gentry, Benton County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 0276-AOP-R6. It produces power using a 6324 million British thermal units (MMBtu) per hour, dry bottom, wall fired Boiler (SN-01) to produce sufficient steam to operate the turbine generator at the 558 MW gross electrical output capability of the unit. The boiler burns primarily low sulfur western coal, but can also combust fuel oil and tire derived fuels (TDF). Fuel oil firing is only allowed during startup and shutdown of the boiler, startup and shutdown of the pulverizer mills, for flame stabilization when the coal is frozen, fuel oil tank maintenance, to prevent boiler tube failure in extreme cold weather, and when the unit is offline for maintenance. Fly ash resulting from the coal combustion process is collected by two hot side electrostatic precipitators. BART determination modeling indicated SN-01 affects Caney Creek and Upper Buffalo Wilderness areas, AR, and Hercules-Glades Wilderness area, MO.

Arkansas Electric Cooperative Corporation - Carl E. Bailey Generating Station (AFIN 74-00024)

is located in Augusta, Woodruff County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 0154-AOP-R4. It produces power using a 1350 MMBtu per hour Riley Stoker Boiler (SN-01) to drive a 122 MW generator. The primary fuel is natural gas but the facility is also permitted to use any grade fuel oil with a sulfur content equal to or below 2.3%. Preliminary modeling of this unit showed emissions affect visibility in Upper Buffalo and Caney Creek Wilderness areas, AR, and Hercules-Glades and Mingo Wilderness areas, MO.

Arkansas Electric Cooperative Corporation - John L. McClellan Generating Station (AFIN 52-00055)

is located in Camden, Ouachita County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 0181-AOP-R5. The plant produces power using a 1436 MMBtu per hour Riley Stoker Boiler (SN-01) to drive a 134 MW generator. The primary fuel is natural gas but the facility is also permitted to use any grade fuel oil with a sulfur content equal to or below 2.8%. Emissions from this source affect Upper Buffalo and Caney Creek Wilderness areas' visibility.

Entergy - Lake Catherine (AFIN 30-00011)

is located in Malvern, Hot Spring County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 1717-AOP-R6. Lake Catherine is a single unit electric generating station which generates electric energy for sale. Three units that were previously in operation were retired in 2014. Unit 4 (SN-03) is the only remaining unit. Electricity for sale is produced by burning natural gas. The burning of No. 6 fuel oil as a secondary fuel has been discontinued. The subject-to-BART source is Unit 4 (SN-03) which is a Combustion Engineering tilting tangential fired 5,850 MMBtu per hour Boiler powering a 552 MW generator. BART determination modeling indicated emissions from this unit affect the visibility at Hercules-Glades, MO, and the Upper Buffalo and Caney Creek Class I areas, AR. The

discontinuance of fuel oil use will result in significant reductions of SO₂ emissions from this source.

Entergy - White Bluff (AFIN 35-00110)

is located in Redfield, Jefferson County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 0263-AOP-R7. Units Nos. 1 (SN-01) and 2 (SN-02) are identical Combustion Engineering tilting tangential 8950 MMBtu per hour coal fired Boilers with a maximum power rating of 850 MW each. The Boilers use sub-bituminous or bituminous coal as the primary fuel and No. 2 fuel oil as a start-up fuel. Particulate matter is controlled by an electrostatic precipitator on each Boiler. The Auxiliary Boiler (SN-05) is a 183 MMBtu per hour Boiler burning No. 2 fuel oil as its only fuel type. The purpose of the Auxiliary Boiler is to provide steam for the start-up of the two primary Boilers, SN-01 and SN-02. Results from the BART determination modeling indicated emissions from Units 1 and 2 and the Auxiliary Boiler affect visibility at Hercules-Glades, MO, and Upper Buffalo and Caney Creek, AR.

Domtar - Ashdown (AFIN 41-00002)

is located in Ashdown, Little River County, AR, and is currently permitted to operate under ADEQ Operating Air Permit Number 0287-AOP-R14. Domtar is a paper mill facility and has two Power Boilers, No. 1 Power Boiler (SN-03) and No. 2 Power Boiler (SN-05), that are subject-to-BART. The No. 1 Power Boiler was installed in 1968 as part of the original construction of the Ashdown Mill. It has a heat input rating of 580 MMBtu per hour and an average steam generating rate of 120,000 pounds per hour (lb/hr) of steam at 850 pounds/square inch [gauge] (psig). It combusts primarily bark, but it is also permitted to burn wood chips, wood waste, recycled sanitary products composed of cellulose and polypropylene, pelletized paper fuel (PPF), TDF, municipal yard waste, No. 6 fuel oil, reprocessed fuel oil, used oil generated on site, and natural gas. Natural gas is only used to supplement other fuels during high steam demand periods. The No.1 Power Boiler is equipped with a traveling grate and a combustion air system. To meet applicable Boiler Maximum Achievable Control Technology (MACT) PM emissions standard of 0.07 lb/MMBtu Domtar Industries installed a wet electrostatic precipitator (WESP) during the spring of 2007. The No. 2 Power Boiler started operation in February 1976. It has a heat input rating of 820 MMBtu per hour and an average steam generating rate of approximately 600,000 lb/hr. It combusts primarily bituminous coal (over 80% of the heat input is supplied by coal), but it is also permitted to burn bark, bark and wood chips used to absorb oil spills, wood waste, petroleum coke, recycled sanitary products based on cellulose and polypropylene, PPF, TDF, municipal waste, No. 6 fuel oil, reprocessed fuel oil, used oil generated on site, natural gas, and non-condensable gases (NCGs). The NCGs are produced in the pulp and evaporator areas. It consist of nitrogen, total reduced sulfur (TRS) compounds, methanol, SO₂, and minor quantities of other compounds such as methyl ethyl ketone (MEK). Under normal conditions, natural gas is not combusted. The No. 2 Power Boiler is equipped with a traveling grate, combustion air system including overfire air, multi-clones, and two parallel venturi scrubbers. The SO₂ loading to the Boiler is significant since it burns

coal and NCGs. Therefore, the scrubbing fluid includes water and a source of alkali, such as sodium hydroxide (NaOH) and/or pulp mill extraction stage filtrate. BART determination modeling indicated emissions from the two Power Boilers affect visibility at Upper Buffalo and Caney Creek, AR.

Georgia-Pacific Paper (AFIN 02-00013)

is located in Crossett, Ashley County, AR, and is currently permitted under ADEQ Operating Air Permit Number 0597-AOP-R15. Georgia-Pacific is a Kraft paper mill that has two subject-to-BART sources, 6A (SN-19) and 9A (SN-22) boilers. The 6A Boiler is a 357 MMBtu per hour boiler. The boiler burns natural gas and specification grade oil. Specification grade oil consists of new oil, used oil, and pitch from the production of tall oil. The 6A Boiler was installed in 1962 and there are no emissions controls associated with it. The 9A Boiler is a 720 MMBtu per hour combination fuel boiler that is used to generate steam for general use throughout the facility. It was installed in 1973. This Boiler may serve as a backup combustion unit when the incinerator (SN-83) is offline. The combination of fuels permitted for this Boiler are TDF, agriculture derived fuel (ADF), refuse derived fuel (RDF), NCGs, wood waste, specification grade oil, natural gas, and sludge. The 9A Boiler is equipped with a wet Venturi scrubber to control sulfur compound emissions. The scrubber was installed in 1980. ADEQ determined 6A Boiler was pre-BART and emissions from 9A Boiler do not cause or contribute to visibility impairment at Caney Creek Wilderness area, AR. However, in the final rule on the 2008 Arkansas Regional Haze SIP, EPA found the 6A Boiler to be BART eligible. EPA also found both the 6A and 9A Boilers to be subject-to-BART and a full BART analysis is required (77 Fed. Reg. 14606). However, Georgia-Pacific (G-P) voluntarily reduced 9A Boiler's permitted SO₂ emission rate to 484.6 tons per year (a 64% reduction). However, permitted PM₁₀ rates increased to 339.0 tpy (from 243.3 tpy). Modeling performed by G-P indicates the current emission rate affects Caney Creek below 0.5 deciview (dv). Based on a call on March 20, 2013, with EPA Region 6 staff and G-P, the current permit limit for the 9A Boiler exempts this facility from the requirement to perform a five-factor analysis.

3. Additional Control Measures – Federal and State Programs

i. Clean Air Interstate Rule (CAIR) and Cross-State Air Pollution Rule (CSAPR)

On May 30, 2012, EPA finalized the rule: “Regional Haze: Revisions to Provisions Governing Alternatives to Source-Specific BART Determinations, Limited SIP Disapprovals, and Federal Implementation Plans” (77 Fed. Reg. 33643, June 7, 2012). This rule allows the trading programs in the CSAPR Rule to serve as an alternative to determining source-by-source BART. This rule provides that states in the CSAPR region can substitute participation in CSAPR for source-specific BART for SO₂ and/or NO_x emissions from power plants. This determination is commonly referred to as CSAPR being “better-than-BART.” EPA also determined “that a state in the Transport Rule region whose EGUs are subject to the requirements of the Transport Rule trading program only for ozone season NO_x is allowed to rely on our determination that the Transport Rule makes greater reasonable progress than source-specific BART for NO_x” (77 Fed.

Reg. 33652). Arkansas is included in this determination, which did not require the state's subject-to-BART EGUs to perform a five-factor analysis of NO_x emissions. However, in light of the U.S. Court of Appeals decision as previously discussed in the Executive Summary to vacate CSAPR and reinstate CAIR, a five-factor analysis of NO_x emissions was developed in Arkansas. On October 12, 2014, the stay of CSAPR was revoked. Beginning May 1, 2015, CSAPR is in effect and being implemented in Arkansas. ADEQ is currently reevaluating the NO_x emission limits that are in the disapproved SIP and considering appropriate revisions. See Table 2.3 for information regarding CAIR sources in Arkansas.

Arkansas's participation in the CAIR NO_x Ozone season only cap and trade program was also a significant component of the State's LTS and was expected to yield EGU NO_x emissions reductions. While CAIR was remanded by the D.C. Circuit Court of Appeals, as previously discussed in the Executive Summary, CAIR remains in effect and sources in Arkansas continue to comply with the state and federal requirements associated with CAIR. Also, as mentioned on the Executive Summary, EPA's request for a three-year delay in the compliance deadline as well as EPA's motion to lift the stay of the CSAPR were granted by the Courts. Until EPA provides guidance to the states, Arkansas will continue its participation in the CAIR NO_x Ozone season only cap and trade program.

Table 2.3. CAIR NO_x Ozone Season Allocations for Arkansas (2009–2017) as Allocated per APC&EC Reg. No. 19.1404.

KEY: <i>(Italics)</i> NEW SOURCE ALLOCATIONS (Plain Text) EXISTING SOURCE ALLOCATIONS *** to be determined										

The following federal rules (40 C.F.R. Part 80, Subpart H; 40 C.F.R. Part 85, 40 C.F.R. Part 86, Subpart P) have offered significant air quality improvement and reductions in visibility-related pollutants.

ii. Tier 2 Vehicle and Gasoline Sulfur Programs

EPA's Tier 2 fleet averaging program for on-road vehicles, modeled after the California LEV (Low Emissions Vehicle) II standards, became effective in the 2005 model year. The Tier 2 program allows manufacturers to produce vehicles with emissions ranging from relatively dirty to very clean, but the mix of vehicles a manufacturer sells each year must have average NO_x emissions below a specified value. Mobile emissions continue to decline as a result of these programs as motorists replace older, more polluting vehicles with newer, cleaner vehicles.

iii. Nonroad Diesel and Ultra-Low Sulfur Diesel (ULSD) Rules

EPA adopted standards for emissions of NO_x, hydrocarbons, and carbon monoxide (CO) from several groups of nonroad engines, including industrial spark-ignition engines and recreational nonroad vehicles. Industrial spark-ignition engines power commercial and industrial applications and include forklifts, electric generators, airport baggage transport vehicles, and a variety of farm and construction applications. Nonroad recreational vehicles include snowmobiles, off-highway motorcycles, and all-terrain vehicles. These rules were initially effective in 2004 and were fully phased in by 2012.

The nonroad diesel rule set standards that reduced emissions by more than 90% from nonroad diesel equipment and, beginning in 2007, the rule reduced fuel sulfur levels by 99% from previous levels. The reduction in fuel sulfur levels applied to most nonroad diesel fuel in 2010 and applied to fuel used in locomotives and marine vessels in 2012.

The low sulfur content mandated by the Ultra-Low Sulfur Diesel (ULSD) Rule resulted in better control particulate emissions from diesel engines. The transition to ULSD for highway vehicles began in June 2006. EPA regulations required that at least 80% of highway diesel fuel in the United States be ULSD, and by 2010, all highway diesel fuel became ULSD. EPA standards also required a major reduction in the sulfur content of diesel fuel intended for use in locomotive, marine, and nonroad engines and equipment including construction, agricultural, industrial, and airport equipment.

iv. 2007 Heavy-Duty Highway Rule

The 2007 Heavy-Duty Highway Rule, also referred as the "Clean Air Highway Diesel Rule," was adopted on January 18, 2001, by EPA as a part of the National Clean Diesel Campaign (NCDC) with the objective of reducing emissions from diesel engines by setting a PM emission standard for new heavy-duty engines, which took effect with the 2007 model year. The rule also required reduction of sulfur in diesel fuel to facilitate the use of modern pollution control technology on these engines. EPA established a goal of reducing emissions from over 11 million diesel engines in the existing fleet by 2014, especially in the sectors of school buses, ports, construction, freight, and agriculture.

ADEQ has undertaken several initiatives to obtain reductions from on-road and nonroad engines, including construction equipment throughout the State. ADEQ offers these funds

annually as a competitive funding assistance opportunity for fleet managers and equipment suppliers entitled “Reduce Emissions from Diesels (Go RED!),” as a means of subsidizing diesel retrofits and the biodiesel market. Although ADEQ cannot provide SIP-quality quantification of the reduction of emissions due to these programs, it is important to note that these efforts have contributed to the state’s improvement of air quality and visibility.

v. Source Retirement and Replacement Schedules

40 C.F.R. § 51.308(d)(3)(v)(B) requires the State of Arkansas to consider measures to mitigate the impacts of construction activities. In accordance with Subchapter 11.4.1.6 of the 2008 Arkansas Regional Haze SIP, ADEQ tracked Prevention of Significant Deterioration (PSD) new sources, source retirements, and replacements. Since 2002, five new PSD facilities have been permitted.

As shown in Table 2.4, these facilities’ total potential to emit (PTE) of NO_x is 5,833 tons per year (tpy) and for SO₂ the total PTE is 7,373.7 tpy. However, as shown by Table 2.5, the total actual emissions, as reported by the facilities in their Annual Emissions Inventory Report, for 2012 for NO_x was lower at 1,740.8 tpy and for SO₂ it was 3,303.2 tpy.

Sixteen PSD facilities have shut down in Arkansas since 2008, resulting in a total reduction of 15,892.5 tpy in permitted NO_x emissions and of 1,125.8 tpy in permitted SO₂ emissions. Table 2.6 shows the actual emissions reductions from these facilities.

vi. Agricultural and Forestry Smoke Management

40 C.F.R. § 51.308(d)(3)(v)(E) requires Arkansas to consider smoke management techniques for the purposes of agricultural and forestry management.

The Arkansas Forestry Commission approved revisions to the Arkansas Smoke Management Plan (SMP) in 2007, which is designed to assure that prescribed fires are planned and executed in a manner designed to minimize impacts associated with the smoke produced by prescribed fires.

4. Maximum Achievable Control Technology (MACT) (40 C.F.R. Part 63)

Since the development of the 2008 Arkansas Regional Haze SIP, EPA has promulgated standards that are anticipated to yield new emissions reductions and have the potential to further reduce emissions associated with visibility impairment in the federal and state Class I areas.

CENRAP estimated emissions reductions from the MACT standards for source categories with post-2002 compliance data⁷. MACT standards not expected to achieve significant VOC emission reductions were excluded. See Table 2.7. This table also provides the associated C.F.R. subpart containing the regulations, the compliance date for existing sources, and the pollutants considered in the 2018 inventory. The list is based upon the data developed by E. H. Pechan and Associates⁸. It is likely that the MACT standards did not significantly impact visibility impairment in Class I areas. CENRAP’s review is provided only as a courtesy and for future reference.

Table 2.7 below describes the MACTs used as control strategies for the non-EGU point source emissions. The table notes the pollutants for which controls were applied as well as the promulgation dates and the compliance dates for existing sources.

Table 2.7. Post-2002 MACT Standards Considered in the 2018 Emissions Inventory

MACT Standard - Source Category	40 C.F.R. Part 63 Subpart	Promulgation (Publication in Federal Register)	Compliance Date (existing sources)	Pollutants Affected
Asphalt (Roofing Manufacturing and Asphalt Processing)	LLLLL	4/29/2003	5/1/2006	VOC
Auto and Light Duty Trucks	IIII	4/26/2004	4/26/2007	VOC
Coke Ovens: Pushing, Quenching and Battery Stacks	CCCCC	4/14/2003	4/14/2006	VOC

⁷ The CENRAP modeling emissions inventory consists of several distinct datasets: the 2002 base case for model performance evaluation, 2002 typical, 2018 base case, and the 2018 control strategy scenario.

5. [Mercury and Air Toxics Rule](#)

On December 16, 2011, the EPA finalized national C.A.A. standards to reduce mercury and other toxic air pollution from coal and oil-fired power plants. The final rule established power plant emission standards for mercury, acid gases, and non-mercury metallic toxic pollutants that will prevent 90% of the mercury in coal burned in power plants from being emitted to the air; reduce by 88% the acid gas emissions from power plants; and cut power plant SO₂ emissions by 41% beyond the reductions expected from CSAPR. Existing EGUs have to comply with this rule by April 16, 2015; however, an additional one-year extension may be granted for compliance if additional time is needed to install controls. Although reductions cannot be quantified at this time, Arkansas anticipates that some reductions in SO₂ emissions from the state's coal-fired EGUs will occur as a result of the MATS rule. Flint Creek plans to install a NID (Novel Integrated Desulfurization) system, while the two Entergy facilities (White Bluff and Independence) currently plan to control mercury by activated carbon injection (ACI). The NID system will control SO₂ and other acid gases, the ACI will not. The remaining coal fired plants in the State (Plum Point and Turk) were constructed with dry flue gas desulfurization and will not be modified.

6. [New NAAQS since the 2008 Arkansas Regional Haze SIP submittal](#)

On January 22, 2010, EPA strengthened the health-based NAAQS for NO₂, establishing a new 1-hour standard at a level of 100 ppb. On January 20, 2012, EPA designated all areas of the country as “unclassifiable/attainment” for the 2010 NO₂ NAAQS.

On June 3, 2010, the EPA promulgated a new 1-hour SO₂ NAAQS at a level of 75 ppb. On August 5, 2013, EPA designated 29 areas in 16 states as nonattainment, none of which are located in Arkansas.

On December 14, 2012, EPA strengthened the PM_{2.5} NAAQS, reducing the level of the annual standard from 15 µg/m³ to 12 µg/m³. EPA is expected to finalize attainment designations by December 14, 2014. Projections provided by EPA suggest 99% of counties with monitors will meet the revised standard by 2020.

ADEQ initiated rulemaking to adopt these standards, except for the 2012 PM_{2.5} NAAQS, into Arkansas's State regulations. APC&EC adopted this rulemaking on August 22, 2014, and ADEQ will incorporate these standards, for PSD sources only, into the SIP.

Chapter 3: Emissions Reductions-40 C.F.R. § 51.308(g)(2)

1. Summary of Emission Reductions Achieved

40 C.F.R. § 51.308(g)(2) requires, “A summary of the emissions reductions achieved throughout the State through implementation of the measures in paragraph (g)(1).”

To meet this requirement, states are required to identify and estimate emissions reductions primarily in NO_x, SO₂, and PM from SIP measures that were discussed in 40 C.F.R. § 51.308(g)(1). As stated in Chapter 2, the BART portion of the 2008 Arkansas Regional Haze SIP was partially approved and partially disapproved. (Please refer to Chapter 2 for the list of disapproved and approved BART elements.) Therefore, as of the submittal date of this report, there have not been any reductions from subject-to-BART sources due to BART limits.

Additional control measures included in the SIP were federal and state programs. Qualitatively, the continued implementation of those federal and state measures discussed in Chapter 2 not affecting point sources are expected to reduce emissions.

Emission data containing annual EGUs SO₂ and NO_x emissions in Arkansas were obtained from EPA’s Clean Air Markets Division (CAMD). (See Table 3.1.)

Table 3.1. Annual NO_x and SO₂ emissions (Arkansas, 2000–2011)⁹

Year	NO _x (tpy)	SO ₂ (tpy)
2000	51,624	75,057
2001	47,398	78,729
2002	42,079	70,738
2003	41,749	73,007
2004	40,083	81,483
2005	35,333	66,190
2006	35,414	73,432
2007	37,877	72,247
2008	37,800	73,289
2009	34,081	68,535
2010	37,785	67,084
2011	38,338	73,623

⁹ Source: U.S. EPA Clean Air Market Division www.epa.gov/airmarkt/

Figure 3.1. Emissions Trends for Arkansas Electric Generation Units (2000–2011)

Looking at the long term (2000–2011), the overall SO₂ and NO_x emissions from Arkansas EGUs are trending downward. (Table 3.1 and Figure 3.1.) Although there was an uptick in 2011, these emissions are less than the 2000 emissions.

2. EGU SO₂ Emission Reductions and Utilization

Figure 3.2 shows a comparison of heat input to observed and projected SO₂ and NO_x emissions for Arkansas EGUs reported to CAMD. As of 2011, SO₂ emissions have increased by 2,885 tpy and NO_x emissions have decreased by 3,741 tpy since 2002. Annual SO₂ emissions are projected to increase by an additional 125 tpy in 2018 from 2011 observed emissions. Annual NO_x emissions are projected to decrease by an additional 10,167 tpy in 2018 from 2011 observed emissions. Although SO₂ emissions from Arkansas EGUs have increased from baseline years 2001–2004 and are projected to continue to do so through 2018, the rate of SO₂ emissions in lb/MMBtu at EGUs has actually decreased. The decrease in emissions rates of SO₂ and NO_x in pounds per MMBtu by Arkansas EGUs, as demonstrated in Figure 3.2, indicates that control efficiencies have improved since 2002 and that projected SO₂ emissions are due to increased activity by EGUs.

Additionally, on June 12, 2013, public notice was issued on SWEPCO/Flint Creek Power Plant's (AFIN 04-00107, Permit No. 027-AOP-R6) draft permit and the final permit was issued on August 25, 2013. This permit was necessary for the installation and operation of new control equipment on source number 01 (SN-01). The installation of this control will reduce the permitted SO₂ emissions by 87.5%. Further SO₂ emission reductions will be realized from existing subject-to-BART sources once the 2008 Arkansas Regional Haze SIP is approved.

Figure 3.2. Arkansas EGU Emissions and Heat Input (2000-2011)

Figure 3.2 shows the rate of SO₂ and NO_x emitted per MMBtu is declining. Although Arkansas’s SO₂ and NO_x emissions have not dropped significantly, the plants are operating more efficiently as shown by ratio of emissions to heat input.

Chapter 4: Assessment of Visibility Conditions—40 C.F.R. § 51.308(g)(3)

1. Introduction

40 C.F.R. § 51.308(g)(3) of the RHR requires for each mandatory Class I area in the state, an assessment of the following visibility conditions and changes, with values for most impaired and least impaired days expressed in terms of five-year averages of these annual values:

- 40 C.F.R. § 51.308(g)(3)(i): *Current visibility conditions for the most and least impaired days.*
- 40 C.F.R. § 51.308(g)(3)(ii): *Difference between current visibility conditions for the most impaired and least impaired days and baseline visibility conditions.*
- 40 C.F.R. § 51.308(g)(3)(iii): *Change in visibility impairment for the most impaired and least impaired days over the past 5 years.*

The goal of the RHR is to restore natural visibility conditions to the mandatory Class I federal areas by 2064. The regional haze SIP must contain measures that make "reasonable progress" toward this goal by reducing anthropogenic emissions that cause haze. Subchapter 2, Assessment of Reasonable Progress Goals, found within this Chapter, will address Arkansas's reasonable progress in detail. For each Class I area, there are three metrics of visibility that are part of the determination of reasonable progress:

- baseline conditions;
- natural conditions; and
- current conditions.

Each of the three metrics includes the concentration data of the visibility impairing pollutants as different terms in the light extinction equation, with respective extinction coefficients and relative humidity factors. The Speciation Trends Network (STN) was later transitioned into the Chemical Speciation Network (CSN) with 50 long-term trend sites and approximately 150 sites operated by state, local, and tribal agencies, primarily in urban/suburban settings.

The primary system used to measure air quality improvements for visibility purposes is the Interagency Monitoring of Protected Visual Environments (IMPROVE¹⁰) program, a cooperative effort between the EPA, federal land management agencies, and state agencies. Air quality measurements in the IMPROVE network began in 1988; as of June 2011, there were 212 sites (170 current and 42 discontinued). In addition, the EPA's STN of 84 sites was originally included to expand the spatial and seasonal aerosol and reconstructed light extinction coefficient

¹⁰ IMPROVE is a network of monitors in various Class I areas, established to assess visibility impairment and its causes.

trends to include urban areas and to investigate the differences in urban and rural aerosol concentrations.

The RHR stipulates use of the IMPROVE algorithm for calculating light extinction in Class I areas. The algorithm uses measured ambient concentrations of light scattering aerosols and humidity to estimate light extinction. The 2011 IMPROVE¹¹ report describes in detail how visibility impairment is calculated. Total light extinction when converted to deciviews is calculated for the average of the 20% least impaired and 20% most impaired visibility days.

The IMPROVE equation¹² is used to convert monitored concentrations into extinction, a measure of visibility. The original IMPROVE equation converts PM species concentrations to light extinction (b_{ext}) as follows:

$$b_{ext} = 3 * f(RH) * [sulfate] + 3 * f(RH) * [nitrate] + 4 * [organic carbon] + 10 * [elemental carbon] + 1 * [fine soil] + 0.6 * [coarse mass] + 10$$

The $f(RH)$ is a water growth factor for sulfate and nitrate; its value depends on relative humidity (RH), ranging from one at low humidity to 18 at 98% humidity. Brackets ([]) represent the concentrations of the PM species measured in micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). The constants are the individual component's extinction efficiency. The 10 that is added accounts for Rayleigh scattering, which is due to the interaction of light with molecules of air itself with no pollutants and is measured in inverse megameters (Mm^{-1}).

In 2007, the IMPROVE workgroup published a more robust algorithm for calculating background visibility.¹³ The revised IMPROVE light extinction equation is expressed as follows:

$$b_{ext} = 2.2 * f_s(RH) * [small sulfate] + 4.8 * f_L(RH) [large sulfate] + 2.4 * f_s(RH) * [small nitrate] + 5.1 * f_L(RH) * [large nitrate] + 2.8 * [small organic mass] + 6.1 * [large organic mass] + 10 * [elemental carbon] + 1 * [fine soil] + 1.7 * f_{ss}(RH) * [sea salt] + 0.6 * [coarse mass] + Rayleigh scattering (site-specific) + 0.33 * [NO₂(ppb)]$$

Sulfate, nitrate, and organic mass are each split into two fractions representing small and large distributions of those species. Though not explicitly shown in the equation, the organic mass concentration used in this new algorithm is 1.8 times the organic carbon mass concentration, changed from 1.4 times carbon mass concentration as used for input for the original IMPROVE

¹¹ *Interagency Monitoring of Protected Visual Environments (IMPROVE) Report V* (2011).

¹³ Pitchford, M. L., W. C. Malm, B. A. Schichtel, N. Kumar, D. Lowenthal, and Hand, J. L. (2007). Revised algorithm for estimating light extinction from IMPROVE particle speciation data, *Journal of the Air and Waste Management Association*, 57, 1326-1336.

algorithm. Sea salt and light absorption by nitrogen dioxide (NO₂) which is measured in parts per billion (ppb) have been added. Distinct water growth curves for small sulfates and nitrates, large sulfates and nitrates, and sea salt have also been added. Site-specific Rayleigh scattering is calculated for the elevation and annual average temperature of each of the IMPROVE monitoring sites compared to the original equation that assumed extinction due to Rayleigh scattering was 10 Mm⁻¹.

2. Assessment of Visibility Conditions for Arkansas Class I Areas

The annual average visibility for 2001–2011 for the 20% best (least impaired) and 20% worst (most impaired) days at Caney Creek and Upper Buffalo Wilderness areas is displayed in Figure 4.1 and Figure 4.2. Visibility conditions have varied from year to year at each Wilderness area. The 2011 data for the least and most impaired days at Caney Creek and Upper Buffalo Wilderness areas shows an improvement in visibility for both areas since 2001.

Figure 4.1. Annual Average Visibility for 20% Best and 20% Worst Days at Caney Creek Wilderness Area, Arkansas (2001–2011)

Figure 4.2. Annual Average Visibility for 20% Best and 20% Worst Days at Upper Buffalo Wilderness Area, Arkansas (2000–2011)

Table 4.1 demonstrates the change in visibility on the 20% worst days at Caney Creek and Upper Buffalo Wilderness areas based on observed data collected between 2001 and 2011 at Caney Creek Wilderness area and collected between 2000 and 2011 at Upper Buffalo Wilderness area. Both areas showed improved visibility from the baseline average in the periods of 2005–2009 and 2007–2011. The current five-year average shows that as of 2011, Caney Creek Wilderness area has achieved 73% of its visibility impairment reduction goal of 3.88 dv and Upper Buffalo Wilderness area has achieved 66% of its visibility impairment reduction goal of 3.75 dv by 2018.

Table 4.1. Visibility at Arkansas Class I Areas on the 20% Worst Days

Class I Area	Monitor ID	Baseline 5-Year Average 2000 – 2004 *(dv)	Current 5-Year Average 2007 – 2011 (dv)	Past 5-Year Average 2005 – 2009 (dv)	Current minus Baseline (dv) 5-Year Average
Caney Creek	CACR	26.55	23.73	25.63	-2.82
Upper Buffalo	UPBU	26.36	23.88	25.93	-2.47

*Data collection at Caney Creek Wilderness area began in 2001; therefore, only four years of data (2001–2004) were used to calculate the baseline.

Table 4.2 shows the five-year averages that were calculated for the 20% best days at Caney Creek and Upper Buffalo Wilderness areas. It also demonstrates the change in visibility on the 20% best days at Caney Creek and Upper Buffalo Wilderness areas based on observed data collected between 2001 and 2011 at Caney Creek Wilderness area and between 2000 and 2011 at Upper Buffalo Wilderness area. Caney Creek Wilderness area showed improved visibility from the baseline average for the periods of 2005–2009 and 2007–2011. Upper Buffalo Wilderness area showed degraded visibility from the baseline average in the average visibility impairment from 2005–2009 and improved visibility from the baseline average for the average of the years 2007–2011.

Table 4.2. Visibility at Arkansas Class I Areas on the 20% Best Days

Class I Area	Monitor ID	Baseline 5-Year Average 2000 – 2004 *(dv)	Current 5-Year Average 2007 – 2011 (dv)	Past 5-Year Average 2005 – 2009 (dv)	Current minus Baseline (dv) 5-Year Average
Caney Creek*	CACR	11.39	10.43	11.06	-0.97
Upper Buffalo	UPBU	11.71	11.04	11.85	-0.67

*Data collection at Caney Creek Wilderness area began in 2001; therefore, only four years of data (2001–2004) were used to calculate the baseline.

3. [Summary](#)

Caney Creek and Upper Buffalo Wilderness areas have both shown improved visibility for the most impaired and least impaired days since 2001 and are projected to continue to improve. Based on the five-year rolling averages and projected data, both Wilderness areas are on schedule to achieve their 2018 RPGs for the 20% worst days. Data from Caney Creek and Upper Buffalo Wilderness areas show that the goal of no visibility degradation on the 20% best days will be achieved and that visibility has and will continue to improve.

Chapter 5: Emissions Inventory Progress—40 C.F.R. § 51.308(g)(4)

The RHR 40 C.F.R. § 51.308(g)(4) requires: “*An analysis tracking the change over the past 5 years in emissions of pollutants contributing to visibility impairment from all sources and activities within the State. Emissions changes should be identified by type of source or activity. The analysis must be based on the most recent updated emissions inventory, with estimates projected forward as necessary and appropriate, to account for emissions changes during the applicable 5 year period.*”

1. Background

The 1990 C.A.A. Amendments require that an Emission Inventory (EI) be prepared statewide for point, nonpoint (area), on-road, and nonroad mobile emissions categories statewide. ADEQ maintains an EI of up-to-date information on emissions of SO₂, VOC, CO, NO_x, lead and lead compounds, ammonia (NH₃), particulate matter less than 2.5 micrometers (PM_{2.5}), and particulate matter less than 10 micrometers (PM₁₀). The EI identifies the types of emissions sources present in an area, the amount of each pollutant emitted, the type of processes occurring, and any control devices employed at each plant or source category. The EI provides data for a variety of air quality planning tasks that include establishing baseline emission levels, calculating emission reduction targets, developing control strategy development for reducing emissions, providing emission inputs into air quality simulation models, and the tracking of emissions over time. These EIs are critical for the efforts of state, local, and federal agencies to demonstrate attainment of the NAAQS.

This chapter discusses general EI development for each of the anthropogenic source categories and compares actual emission trends with modeled projections for the State as a whole (all sources) as well as for electric generating utilities within the State.

2. Industrial Point Sources

Stationary point source emission data is collected annually from those sources that meet reporting requirements outlined in the Air Emissions Reporting Requirements (40 C.F.R. Part 51). These sources include, but are not limited to, refineries, chemical plants, bulk terminals, and utilities. Facilities are required to report emissions data to ADEQ. Reporting of information characterizing the process equipment, the abatement units, and the emission points is also required. All data submitted is reviewed for quality assurance purposes and then stored in the State and Local Emissions Inventory System (SLEIS) database. At the end of the annual reporting cycle, point source emission data is reported each year to the EPA for inclusion in the National Emissions Inventory (NEI).

3. Area Sources

Stationary sources that do not meet the reporting requirements for point sources are classified as area sources. Area sources are small-scale industrial, commercial, and residential sources that use materials or perform processes that generate emissions. Area sources can be characterized by the mechanism in which emissions are released into the atmosphere: evaporative or combustion. Evaporative emission sources include the following: oil and gas production facilities, printing processes, industrial coating and degreasing operations, gasoline service station underground tank filling, and vehicle refueling operations. Combustion sources include the following small facilities with less than 100 tons per year of emissions: oil and gas production facilities, stationary source fossil fuel combustion at residences and businesses, outdoor burning, structural fires, and wildfires.

Arkansas accepts EPA emission estimates for the Area Sources category.

4. On-Road Mobile Sources

On-road mobile sources consist of passenger cars, passenger trucks, motorcycles, buses, heavy-duty trucks, and other motor vehicles traveling on public roadways. Combustion-related emissions are estimated for vehicle engine exhaust, and evaporative hydrocarbon emissions are estimated for the fuel tank and other non-tailpipe sources from the vehicle. To calculate pollution from on-road mobile sources, emission rates are estimated as a function of county, vehicle type, roadway type, hour, and operating speed. These rates are then matched with appropriate activity from transportation data sources such as vehicle miles traveled (VMT), number of vehicles parked, hours spent in extended idle mode, etc.

Arkansas accepts EPA emission estimates for sources in the On-Road Mobile category.

5. Nonroad Mobile Sources

Nonroad mobile sources include vehicles, engines, and equipment used for construction, agriculture, transportation, recreation, and many other purposes. Nonroad vehicles are also referred to as off-road or off-highway vehicles and do not normally operate on roads or highways. This broad category is composed of a diverse collection of machines, many of which are powered by diesel engines. Examples of nonroad mobile sources include, but are not limited to: agricultural equipment, commercial and industrial equipment, construction and mining equipment, lawn and garden equipment, aircraft, locomotives, and commercial marine vessels.

Arkansas accepts EPA emission estimates for sources in the Nonroad Mobile category.

6. Emissions Data

Table 5.1 shows the consolidated 2002, 2005, 2008, and 2011 NEI emissions data as well as the 2018 projected inventory from the 2008 Arkansas Regional Haze SIP. Please note that the Emissions Data for 2011 was obtained from the 2011 NEI version 1.

Source: EPA EIS

7. Statewide Emissions Data Comparison

In the 2008 Arkansas Regional Haze SIP, actual 2002 inventory data was used to forecast 2018 emissions. Projected 2018 emission data, the approach used to develop the projections, and the modeling data were summarized in two chapters of the 2008 Arkansas Regional Haze SIP: Chapter 7 Emissions Inventory and Chapter 8 Modeling Assessment.

CENRAP-sponsored regional haze SIP modeling predicted that emissions of both NO_x and PM₁₀ would decrease between 2002 and the projected 2018 inventory. Increases in statewide emissions were predicted between 2002 and 2018 for both SO₂ and PM_{2.5}.

Emission changes were seen in the on-road mobile source inventory between 2008 and 2011 as a result of the transition from EPA's MOBILE6 model to the Motor Vehicle Emission Simulator (MOVES) model for estimation of emissions. Increases in on-road mobile source PM₁₀ and PM_{2.5} emissions have been documented¹⁴ as part of the new model's estimation methodology. The transition to MOVES model estimation methodology also resulted in increased NO_x emissions for on-road mobile sources¹⁵. These modeling changes may account for the increased emission estimates for PM₁₀, PM_{2.5}, and NO_x as EPA estimates were accepted by Arkansas for the 2011 NEI. EPA modeling figures for fires accounted for a major portion of the estimated emission increase for PM_{2.5} from 2008 to 2011. EPA figures for fires were also responsible for much of the estimated emission increase for NO_x from 2005 to 2008. EPA estimates (mainly

¹⁴ U.S. EPA. (2009). "Draft MOVES2009" for Comment: Questions and Answers. April.

fugitive dust, road dust, agriculture, and fires) accounted for a major portion of the estimated emission increase for PM₁₀ from 2005 to 2011.

The SO₂ emissions decreased between 2005 and 2011 as a result of phasing in low sulfur [500 parts per million (ppm)] ULSD fuels for nonroad, locomotive, and marine engines beginning in 2007. These lower sulfur fuel requirements, coupled with advanced emission control technologies, are expected to decrease emissions from these engines between 2007 and 2014.

Figure 5.1. Comparison of Arkansas's Actual Emissions for 2002, 2005, 2008, and 2011 with the 2018 CENRAP Projected Emissions

Emissions from 2002 are compared to 2011 emissions in Tables 5.2, 5.3, and 5.4.

Table 5.2. Summary of Arkansas Emissions from the 2002 NEI (tons)

^a Apparent increases in PM₁₀ and PM_{2.5} emissions from the fugitive dust and road dust categories are predominantly, if not wholly attributable to the 2011 emissions not being reduced by transport factors.

It was also noted that overall efficiency of EGU facilities has been increasing. This conclusion was based on the observation that the rate of heat input has increased at a higher rate than the rate of SO₂ and NO_x emissions. (See Figure 5.2.)

Figure 5.2. Actual Annual Emissions of SO₂ and NO_x and Heat Input (in 1000 MMBtu) in 2002, 2005, 2008 and 2011 as Reported to CAMD (Includes All Units Reporting to CAMD), and Projected 2018 Emissions

As predicted in the CENRAP-sponsored regional haze SIP modeling projections for 2018, estimated PM_{2.5} emissions have increased from 2002 to 2011. Estimated emissions of PM₁₀ and NO_x have also increased from 2002 to 2011. The increase in estimated emissions for both PM₁₀ and NO_x may be due to the use of newer modeling methodologies that have been developed since the 2018 projections were made. The reported PM₁₀ emissions from Point Source EGUs generally increased between 2002 and 2011; however, these emissions are projected to decrease by 2018. Although overall emissions for both NO_x and PM_{2.5} have increased from 2002 to 2011, the reported PM_{2.5} emissions from Point Source EGUs generally decreased between 2002 and 2011 while NO_x emissions from Point EGU sources were also lower in 2011 than in 2002. The majority of the NO_x, PM₁₀ and PM_{2.5} emission estimates referenced in Figure 5.1 for Point Source EGUs were obtained from NEI reports, which included data obtained directly from the reporting facilities. Those emission values therefore represent the most accurate data available at the time this document was developed. The remaining NO_x, PM_{2.5}, and PM₁₀ emissions that contributed to the overall increases were the results of EPA modeling. EPA-modeled emissions may have seen increases resulting from the use of newer modeling methodologies between 2005 and 2011. There was a decrease in estimated SO₂ emissions between 2002 and 2011 and this is likely due to phasing in of low sulfur fuels that may not have been factored into the original 2018 predictions.

8. Summary

As required in 40 C.F.R. § 51.308(g)(4), Arkansas analyzed changes in emissions of pollutants contributing to visibility impairment from sources within the State. Table 5.4 indicates that total SO₂ emissions have decreased since 2002. Although NEI emission figures for NO_x, PM₁₀, and PM_{2.5} have shown a general increase from 2002 to 2011, much of the increase for these pollutants is based on emission modeling/estimates from EPA. These modeled emissions may have shown increases due to the use of newer modeling methodologies that were not available when the baseline projections were developed in 2002. It was also observed, as shown on Table 5.1 and Table 5.4, NO_x, PM₁₀ and PM_{2.5} are trending down in the Point EGU category.

Chapter 6: Assessment of Changes Impeding Visibility Progress—40 C.F.R. § 51.308(g)(5)

1. Introduction

40 C.F.R. § 51.308(g)(5) requires: “*An assessment of any significant changes in anthropogenic emissions within or outside the State that have occurred over the past five years that have limited or impeded progress in reducing pollutant emissions and improving visibility.*”

To address 40 C.F.R. § 51.308(g)(5), Arkansas is explicitly indicating there were no significant changes in the anthropogenic emissions of concern that have limited or impeded progress in reducing pollutant emissions and improving visibility. Further information on how Arkansas is assessing visibility emissions in both of its Class I areas can be found in Chapter 4, Assessment of Visibility Conditions, which addresses Arkansas’s reasonable progress in detail, and Chapter 5, Emissions Inventory Progress, which provides the general EI development for each of the anthropogenic source categories.

Chapter 7: Assessment of Current Strategy to Meeting Reasonable Progress Goals–40 C.F.R. § 51.308(g)(6)

1. Introduction

40 C.F.R. § 51.308(g)(6) of the RHR requires: “*An assessment of whether the current implementation plan elements and strategies are sufficient to enable the State, or other States with mandatory federal Class I areas affected by emissions from the State, to meet all established reasonable progress goals.*”

EPA, as discussed in the Executive Summary, disapproved the RPGs set forth in the 2008 Arkansas Regional Haze SIP. The evaluation set forth in this chapter is based on the RPGs as established in the 2008 Arkansas Regional Haze SIP. ADEQ is presently working on revisions to the SIP to address the portions that EPA disapproved.

ADEQ has assessed the current SIP elements and strategies and determined that, based upon relevant data (i.e. projected emissions and modeling results), they are sufficient to enable Arkansas and other states with Class I areas affected by emissions from Arkansas to meet all established reasonable progress goals.

2. Control Measures in the 2008 Arkansas Regional Haze SIP

As stated in the 2008 Arkansas Regional Haze SIP, the CENRAP modeling showed that Arkansas’s Class I areas could achieve the 2018 RPGs without additional control measures beyond those described in the SIP.

The 2008 Arkansas Regional Haze SIP described emission reductions that would produce a 2018 outcome that could show progress toward the goal of natural background conditions and therefore it was concluded that there was not an immediate need to evaluate additional control measures beyond BART. This portion of the SIP was disapproved by EPA. Arkansas will reevaluate the need for additional control measures by performing the four-factor analysis described in 40 C.F.R. § 51.308(d)(1)(i)(A) and submit its findings as part of the responses to the disapproved portions of the 2008 Arkansas Regional Haze SIP. During this reevaluation process, ADEQ will work with EPA.

3. Assessment of Reasonable Progress Goals

The RHR at 40 C.F.R. § 51.308(d)(1) requires states to establish RPGs (in dv) for each Class I area within the state that provide for reasonable progress towards achieving natural visibility. In the 2008 Arkansas Regional Haze SIP, the Department established RPGs for reduction of visibility impairment by 2018 to demonstrate consistency with the uniform rate of progress needed to achieve natural background conditions by 2064 in Caney Creek and Upper Buffalo Wilderness areas. For Caney Creek Wilderness area, the Department established a RPG of 3.88

dv reduction in visibility impairment by 2018 for the 20% worst days. A 2018 RPG of 3.75 dv reduction in visibility impairment on the 20% worst days was established for Upper Buffalo Wilderness area. These RPGs should result in visibility improvement that exceeds the uniform rate of progress needed to achieve natural background conditions by 2064. The Department also established a goal of no visibility degradation for the 20% best days for Caney Creek and Upper Buffalo Wilderness areas. Based on the RPGs established by the Department, visibility at Caney Creek and Upper Buffalo Wilderness areas could achieve background conditions by 2062 and 2063, respectively.

An assessment of visibility improvement progress for the 20% worst days at Caney Creek Wilderness area is depicted in Figure 7.1. A glide path has been drawn to indicate the uniform rate of visibility improvement required to reach the goal of natural conditions by 2064. The most recent data from 2011 and the current five-year rolling average (2007–2011) show that visibility impairment is decreasing more rapidly than the glide path and the RPG. Based on current data and without additional controls on sources, Caney Creek Wilderness area is expected to achieve its 2018 RPG of 3.88 dv of visibility improvement for the 20% worst days.

Figure 7.1. Reasonable Progress Assessment Caney Creek Wilderness Area, Arkansas: 20% Worst Days

An assessment of visibility improvement progress for the 20% worst days at Upper Buffalo Wilderness area is depicted in Figure 7.2. A glide path has been drawn to indicate the uniform rate of visibility improvement required to reach the goal of natural conditions by 2064. The most recent data from 2011 and the current five-year rolling average show that visibility impairment is decreasing more rapidly than the glide path and the RPG. Based on current data, and without additional controls on sources, Upper Buffalo Wilderness area is expected to achieve its 2018 RPG of 3.75 dv of visibility improvement for the 20% worst days.

Figure 7.2. Reasonable Progress Assessment Upper Buffalo Wilderness Area, Arkansas 20% Worst Days

An assessment of visibility improvement progress for the 20% best days at Caney Creek Wilderness area is depicted in Figure 7.3. A glide path has been drawn to indicate the uniform rate of visibility improvement required to reach natural visibility conditions by 2064. Although the most recent observed data collected in 2011 shows that visibility impairment on the 20% best days was greater than the baseline, the five-year rolling average shows a reduction in visibility impairment from the baseline.

Figure 7.3. Reasonable Progress Assessment Caney Creek Wilderness Area, Arkansas 20% Best Days

Figure 7.4 depicts an assessment of visual improvement progress for the 20% best days at Upper Buffalo Wilderness area. The five-year rolling average and the most recent observed data (2011) for visual impairment for the 20% best days are below the baseline.

Figure 7.4. Reasonable Progress Assessment Upper Buffalo Wilderness Area, Arkansas 20% Best Days

Source: VIEWS, <http://views.cira.colostate.edu/web/>

Prepared by Mary Pettyjohn, Epidemiologist

4. Visibility Improvements at Class I Areas in Other States

As indicated in the above subchapter, Assessment of Regional Progress Goals, Caney Creek and Upper Buffalo Wilderness areas show an improvement in visibility for both areas from the baseline average in the 2005–2009 and 2007–2011 periods. The current five-year average indicates that as of 2011, Caney Creek Wilderness area has achieved 73% of its visibility impairment reduction goal of 3.88 dv and Upper Buffalo Wilderness area has achieved 66% of its visibility impairment reduction goal of 3.75 dv by 2018.

Also indicated in the RPG assessment, the two Class I areas in another state which may be impacted by facilities in Arkansas (Hercules Glade, MO and Mingo, MO) have demonstrated visibility improvement for the least and most impaired days between 2000 and 2011 as shown in Table 7.1 and Table 7.2.

Table 7.1 demonstrates the change in visibility on the 20% worst days at Hercules Glade and Mingo Wilderness areas based on observed data collected between 2001 and 2011. Table 7.2 demonstrates the change in visibility on the 20% best days at Hercules Glade and Mingo Wilderness areas based on observed data collected between 2001 and 2011.

Table 7.1. Visibility at Nearby Class I Areas for the 20% Worst Days

Class I Area	Monitor ID	Baseline 5-Year Average 2000 – 2004 (dv)	Current 5-Year Average 2007 – 2011 (dv)	Past 5-Year Average 2005 – 2009 (dv)	Current minus Baseline	Past minus Baseline
Hercules-Glade, MO	HEGL	26.90	24.62	26.15	-2.28	-0.75
Mingo, MO	MING	28.40	26.48	27.10	-1.92	-1.30

Table 7.2. Visibility at Nearby Class I Areas for the 20% Best Days

Class I Area	Monitor ID	Baseline 5-Year Average 2000 – 2004 (dv)	Current 5-Year Average 2007 – 2011 (dv)	Past 5-Year Average 2005 – 2009 (dv)	Current minus Baseline	Past minus Baseline
Hercules-Glade, MO	HEGL	12.82	11.71	12.55	-1.11	-0.27
Mingo, MO	MING	14.30	13.47	13.90	-0.83	-0.40

Chapter 8: Visibility Monitoring Strategy Review – 40 C.F.R. § 51.308(g)(7)

1. Introduction

40 C.F.R. § 51.308(g)(7) requires: “*A review of the State’s visibility monitoring strategy and any modifications to the strategy, as necessary.*”

The monitoring strategy for regional haze in Arkansas relies upon participation in the IMPROVE network, which is the primary monitoring network for regional haze nationwide. The IMPROVE network provides the only long-term record for tracking visibility improvement or degradation, therefore, Arkansas intends to rely on data collected through the IMPROVE network to satisfy the regional haze monitoring requirement as specified in 40 C.F.R. § 51.308(d)(4) of the RHR.

EPA’s approval (77 Fed. Reg. 14604) of several core elements of the 2008 Arkansas Regional Haze SIP included the SIP’s proposed regional haze monitoring strategy.

2. Monitoring at Class I Areas in Arkansas

In Arkansas, IMPROVE sites are located at the 14,460 acre Caney Creek Wilderness area in the Ouachita National Forest in Polk County, and the 11,801 acre Upper Buffalo Wilderness area in the Ozark National Forest in Newton County. Upper Buffalo Wilderness area includes the original Wilderness and the additions to it. It does not include the Buffalo National River. In addition to the IMPROVE monitor, the Upper Buffalo Wilderness area monitor site also includes a nephelometer and a meteorological monitor. The applicable FLM for these areas is the Forest Service under the U.S. Department of Agriculture (USDA).

The IMPROVE measurements are critical to Arkansas’s regional haze monitoring strategy, and it is difficult to visualize how the objectives listed above could be met without the monitoring and sample analysis provided by IMPROVE. Any reduction in the scope of the IMPROVE network in Arkansas would jeopardize the State’s ability to demonstrate reasonable progress toward visibility improvement in its Class I areas. In the event of such reduction affecting Arkansas’s ability to track regional haze impacts in Class I areas, Arkansas, in consultation with EPA and relevant FLM, will develop an alternative approach for meeting the tracking goal (e.g., relying on nearby urban monitoring sites or seeking contingency funding for limited monitoring).

Additionally, Upper Buffalo Wilderness area’s visibility is monitored by a webcam serviced by the U.S. Forest Service. Real-time images can be viewed at <http://www.fsvisimages.com>.

3. Reporting Visibility Monitoring Data to EPA

Arkansas is committed to meeting the requirements under 40 C.F.R. § 51.308(d)(4)(iv), and reports to EPA visibility data for each of the Arkansas Class I areas annually. For the Five-Year Regional Haze Progress Report, Arkansas has evaluated its monitoring network and found there have not been any changes from the 2008 Arkansas Regional Haze SIP network.

Table 8.1. Arkansas Class I Areas Identification and Operational Dates

Class I Area	Monitor ID	State	Latitude	Longitude	Elevation Mean Sea Level (msl)	Dates of Operation
Caney Creek Wilderness	CACR1	AR	34.4544	-94.1429	683.00	6/22/2000 to present
Upper Buffalo Wilderness	UPBU1	AR	35.8258	-93.203	722.75	12/18/1991 to present

The filter samples from the IMPROVE monitors are sent for analysis to the Crocker Nuclear Laboratory of the University of California in Davis and the data is posted to the IMPROVE website at <http://vista.cira.colostate.edu/improve> and the Visibility Information Exchange Websystem (VIEWS) website at <http://views.cira.colostate.edu/web/>.

Data produced by the IMPROVE monitoring network will be used nearly continuously for preparing the five-year progress reports and the 10-year SIP revisions, each of which relies on analysis of the preceding five years of data. Consequently, the monitoring data from the IMPROVE sites needs to be readily accessible and to be kept up-to-date.

See Chapter 5 for monitoring data and assessment of changes impending visibility progress from 2000 to the latest quality assured IMPROVE data.

Chapter 9: Determination of Adequacy—40 C.F.R. § 51.308(h): Recommendations for Five-Year Progress Report

1. Introduction

40 C.F.R. § 51.308(h) or the RHR requires, “...*At the same time the State is required to submit any 5-year progress report to EPA in accordance with paragraph (g) of this section, the State must also take one of the following actions based upon the information presented in the progress report:*

- (1) ...provide to the Administrator a negative declaration that further revision of the existing implementation plan is not needed at this time;*
- (2) If the State determines that the implementation plan is or may be inadequate to ensure reasonable progress...the State must provide notification to the Administrator and to the other States which participated in the regional planning process...must also collaborate with the other States through the regional planning process for the purpose of developing additional strategies to address the plan’s deficiencies;*
- (3) Where...the implementation plan is or may be inadequate ...due to emissions from sources in another country, the State shall provide notification, along with available information, to the Administrator; or*
- (4) Where the State determines that the implementation plan is or may be inadequate to ensure reasonable progress due to emissions from sources within the State, the State shall revise its implementation plan to address the plan’s deficiencies within one year.”*

2. Negative Declaration

Based on the options above and the evidence presented herein, ADEQ is providing a negative declaration to the EPA Administrator, specifying that no additional controls are necessary during this first five-year progress report period. ADEQ is committed to correcting the portions of the 2008 Arkansas Regional Haze SIP that EPA disapproved.

In keeping with the EPA’s recommendations related to consultation, ADEQ enlisted the support of appropriate state, local and tribal air pollution agencies, as well as the corresponding FLMs to formulate this report. As part of this commitment, the Department made an advanced, draft copy of this report available to the aforementioned agencies and sought their input. Comments received, along with the Department’s responses can be found under Appendix A: Interagency Consultation. Those comments seen as germane were taken into account in developing this progress report.

In addition, the Department also published a Notice of Public Hearing and Comment Period in the *Arkansas Democrat Gazette* on January 2, 2015, and provided a 30-day public comment period. A public hearing, was held on February 2, 2015. A copy of the public notice and Response to Comments can be found under Appendix D: Evidence Public Notice Was Given, and under Appendix F: Compilation of Public Comments and Response to Comments.

ADEQ remains committed to continued consultation with other relevant states and FLMs for this SIP revision and/or the implementation of other programs having the potential to contribute to visibility impairment in much the same fashion as did the pre-hearing meetings, comments, and responses, as required by 40 C.F.R. § 51.308(i)(3) and included under Appendix A: Interagency Consultation.

Chapter 10: Consultation with Federal Land Managers—40 C.F.R. § 51.308(i)(2)-(3)

1. Introduction

The state must provide the FLM with an opportunity for consultation, in person and at least 60 days prior to holding any public hearing on an implementation plan (or plan revision) for regional haze required by this subpart. This consultation must include the opportunity for the affected Federal Land Managers to discuss their:

- (i) *Assessment of impairment of visibility in any mandatory Class I Federal area; and*
- (ii) *Recommendations on the development of the reasonable progress goal and on the development and implementation of strategies to address visibility impairment.*

In developing any implementation plan (or plan revision), the state must include a description of how it addressed any comments provided by the FLM.

2. Consultations

CenSARA arranged conference calls, which took place on February 27, 2012, April 30, 2013, July 30, 2013, August 13, 2013, and September 12, 2013, for the central states with the FLM who would be reviewing the five-year regional haze SIPs. The FLM offered suggestions on the content of the five-year SIP revisions as no further guidance had been provided by the EPA since the 1999 RHR at the time of this document development. The FLM representative suggested that states focus on the data in the 2011 Interagency Monitoring of Protected Visual Environments (IMPROVE) report, which analyzed the Class I area network data for five years, charted trends for each Class I area, and presented national trends. On April 12, 2013, the EPA released a guidance document to assist states in addressing the requirements for a five-year regional haze SIP revision, titled *General Principles for the 5-Year Regional Haze Progress Reports for the Initial Regional Haze State Implementation Plans (Intended to Assist States and EPA Regional Offices in Development and Review of the Progress Reports)*.

The RHR requires that this SIP revision be reviewed by the appropriate FLMs and EPA before the SIP goes to public comment. The rule requires that FLMs be given 60 days to comment on Arkansas's SIP and that these comments be available to the public during the public comment period. As with the previous Regional Haze SIP revision, after the State receives comments from the federal agencies, ADEQ and FLMs and/or the EPA may confer on the federal comments for intent, clarification, or other reasons.

To enhance interstate consultation efforts, ADEQ submitted a draft SIP to the State of Missouri concurrently with the FLM review period. ADEQ has been and continues to be available for consultation concerning the Class I areas located in Arkansas.

3. FLM Comment Period

The FLM comment period opened on April 25, 2014, and closed on June 24, 2014, but it was extended until June 27, 2014, per FLM request. Comments were submitted to Tony Davis at the Arkansas Department of Environmental Quality, 5301 Northshore Dr., North Little Rock, AR 72118-5317.

Re: Arkansas Five-Year Regional Haze Progress Report State Implementation Plan (SIP)
Revision Draft

Dear Mr. Donaldson:

This letter serves to notify you that the Arkansas Department of Environmental Quality (ADEQ) has prepared the Five-Year Regional Haze Progress Report draft SIP and we would appreciate your review. For your convenience, a hard copy of the draft SIP and a disc with an electronic copy are enclosed.

We also would like to inform you, in accordance with 40 C.F.R. § 51.308(i), ADEQ is to consult with the Federal Land Managers (FLMs) responsible for Class I areas where visibility may be impacted by Arkansas sources, and we have submitted to them also a copy of this draft SIP for their revision. We expect to receive their formal comments by June 24, 2014, prior to ADEQ holding a public hearing to solicit public comments.

Should you have any questions, please contact Mark McCorkle at 501-682-0736 or by email at mac@adeq.state.ar.us.

Sincerely,

A handwritten signature in black ink, appearing to read "Mike Bates", with a long horizontal flourish extending to the right.

Re: Arkansas Five-Year Regional Haze Progress Report State Implementation Plan (SIP)
Revision Draft

Dear Ms. Vit:

This letter serves to notify you that the Arkansas Department of Environmental Quality (ADEQ) has prepared the Five-Year Regional Haze Progress Report draft SIP.

We also would like to inform you, in accordance with 40 C.F.R. § 51.308(i), ADEQ is to consult with the Federal Land Managers (FLMs) responsible for Class I areas where visibility may be impacted by Arkansas sources, and we have submitted to them also a copy of this draft SIP for their review. We requested their formal comments to be submitted by June 24, 2014, prior to ADEQ holding a public hearing to solicit public comments.

In order to enhance interstate consultation, we are submitting this draft SIP for your information. For your convenience, a hard copy of the draft SIP and a disc with an electronic copy are enclosed. We would appreciate if you could send us any comments by June 24, 2014.

Should you have any questions, please contact Mark McCorkle at 501-682-0736 or by email at mac@adeq.state.ar.us.

Sincerely,

Re: Arkansas Five-Year Regional Haze Progress Report State Implementation Plan (SIP)
Revision Draft

Dear Mr. Allen:

This letter serves to notify you that the Arkansas Department of Environmental Quality (ADEQ) has prepared the Five-Year Regional Haze Progress Report draft SIP. In accordance with 40 C.F.R. § 51.308(i), ADEQ is to consult with the Federal Land Managers (FLMs) responsible for Class I areas where visibility may be impacted by Arkansas sources. We believe that such consultation can be sufficiently accomplished via phone or written communication, including email and/or letter. However, if your agency desires an in-person consultation or teleconference, please advise us as soon as practicable, but no later than 30 days after receipt of this submittal. For your convenience, a hard copy of the draft SIP and a disc with an electronic copy are enclosed.

As part of the consultation process, FLMs have 60 days to review the draft SIP revision, prior to ADEQ holding a public hearing to solicit public comments. Therefore, ADEQ requests you to acknowledge April 25, 2014, as the formal commencement of the required 60-day review period. We would appreciate your formal comments by June 24, 2014, via conventional mail, express courier or by email to the address below. Should you have any questions, please contact Mark McCorkle at 501-682-0736 or by email at mac@adeq.state.ar.us.

Sincerely,

Re: Arkansas Five-Year Regional Haze Progress Report State Implementation Plan (SIP)
Revision Draft

Dear Mr. Wagoner:

This letter serves to notify you that the Arkansas Department of Environmental Quality (ADEQ) has prepared the Five-Year Regional Haze Progress Report draft SIP. In accordance with 40 C.F.R. § 51.308(i), ADEQ is to consult with the Federal Land Managers (FLMs) responsible for Class I areas where visibility may be impacted by Arkansas sources. We believe that such consultation can be sufficiently accomplished via phone or written communication, including email and/or letter. However, if your agency desires an in-person consultation or teleconference, please advise us as soon as practicable, but no later than 30 days after receipt of this submittal. For your convenience, a hard copy of the draft SIP and a disc with an electronic copy are enclosed.

As part of the consultation process, FLMs have 60 days to review the draft SIP revision, prior to ADEQ holding a public hearing to solicit public comments. Therefore, ADEQ requests you to acknowledge April 25, 2014, as the formal commencement of the required 60-day review period. We would appreciate your formal comments by June 24, 2014, via conventional mail, express courier or by email to the address below. Should you have any questions, please contact Mark McCorkle at 501-682-0736 or by email at mac@adeq.state.ar.us.

Sincerely,

Mike Bates

Dear Mr. Bates:

Thank you for the opportunity to review and comment on Arkansas's draft State Implementation Plan Review for the Five-Year Regional Haze Progress Report. While the draft report demonstrates that visibility is improving at Class I areas in Arkansas and Missouri, there is no demonstration that Arkansas is implementing all the reasonable control measures necessary to meet the 2018 reasonable progress goals for Class I areas in Arkansas and neighboring states. In March 2012, EPA disapproved portions of Arkansas' 2008 Regional Haze State Implementation Plan (SIP) that addressed Best Available Retrofit Technology, the long term strategy, and reasonable progress goals. Arkansas has not revised the 2008 Regional Haze SIP to resolve the deficiencies identified by EPA. For reasons outlined below, we do not agree with Arkansas' conclusion that the requirements of 40 CFR 51.308(g) have been met, nor can we support Arkansas' determination that no further actions are required.

Our specific comments follow:

Chapter 2.1: The description of pollutant contributions to haze on the 20% worst days at Caney Creek and Upper Buffalo Wilderness Areas (WAs) is good. Figures 2.1 and 2.2 demonstrate that sulfate is the largest contributor to haze of the 20% worst days. Figure 2.3 demonstrates that Electric Generating Units (EGU) and non-EGU point sources are the largest contributors to sulfur dioxide (SO₂) emissions in Arkansas. Therefore we would expect Arkansas to concentrate on reducing point source SO₂ emissions in the long-term strategy.

Chapter 3.1: Table 3.1 indicates that annual emissions of SO₂ from EGU in Arkansas actually increased between 2002 and 2011, while nitrogen oxide (NO_x) emissions decreased slightly. No information is presented about expected emissions reductions from existing EGU between 2011 and 2018 to support the 2018 emissions projections in Table 5.1. The information presented does not demonstrate reasonable progress in reducing point source emissions. Please identify any source specific controls planned and CAIR or CSAPR caps that have yet to be met that would require controls on these sources.

Chapter 5: There is a typo in sentence on top of page 50: Tables 5.2, 5.3, and 5.4 compare 2002 and 2011 emissions, not 2018 emissions. We recognize that emissions from area, non-road, and on-road sectors are calculated by EPA. Our concerns focus on point EGU and non-EGU facilities that are directly permitted by Arkansas and the lack of information supporting 2018 emissions projections.

Chapter 7: In 2012 EPA disapproved Arkansas's BART determinations and reasonable progress goals for 2018. Arkansas has not yet corrected the deficiencies in the 2008 SIP. Arkansas' draft 5-year progress report addresses goals that have been disapproved.

Arkansas commits on page 50 to work with EPA as it performs the required 4-factor analyses. We ask that Arkansas also consult with the affected Federal Land Managers.

Arkansas has not demonstrated that it is reducing emissions contributing to visibility impairment at Class I areas in neighboring states. Section 7.4 does not explain why Hercules Glade and Mingo WAs in Missouri were the only Class I areas reviewed. Arkansas should cite the CENRAP source apportionment analyses that show the contribution of Arkansas point, area, and mobile sources at neighboring Class I areas, compared to sources in other states.

For the reasons above, we disagree with Arkansas' conclusion that no additional actions are needed as part of this five year review. We encourage Arkansas to complete revisions to the 2008 Regional Haze SIP before requesting EPA approval of the 5-year regional haze progress report. If you have questions about our comments, please contact Pat Brewer of my staff at (303) 969-2153.

Dear Ms. Marks:

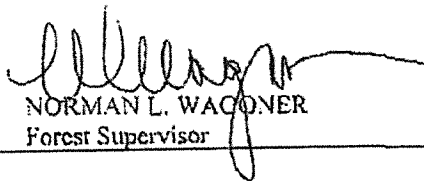

The U.S. Forest Service (FS) appreciates the opportunity to review and comment on the State Implementation Plan Review for the Five-Year Regional Haze Progress Report prepared by the Arkansas Department of Environmental Quality (ADEQ).

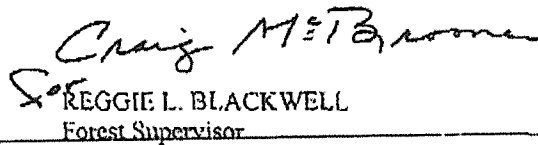

We are providing these comments to ADEQ, and ask that they be placed in the official public record. We look forward to your response as per section 40 CFR §51.308 (i)(3) and are willing to work with ADEQ staff towards addressing any of the issues discussed in this letter.

Again, we appreciate the opportunity to work closely with ADEQ to improve Arkansas's air quality and visibility. We thank you for the good working relations we have with you in our prescribed burning program.

If you have any questions, need clarification, or would like to discuss our comments, please feel free to contact Judy Logan at 501-321-5341. You may also contact Mr. Blackwell or Mr. Wagoner at the numbers listed above.

Sincerely,

FS Comments regarding ADEQ's Proposed Regional Haze Implementation Plan Revision of June 23, 2014

The Forest Service (FS) appreciated the opportunity to comment on the proposed Regional Haze plan revision.

Arkansas Department of Environmental Quality (ADEQ) submitted a Regional Haze (RH) plan to the Environmental Protection Agency (EPA) on September 23, 2008. On March 12, 2012, EPA took action and partially approved and partially disapproved the Arkansas Regional Haze State Implementation Plan (SIP). The FS submitted comments on June 6, 2008. We had several areas of concern in 2008 that we again bring forward. Specifically, we are still concerned how Best Available Retrofit Technology (BART) decisions are being handled as well as the treatment of Reasonable Progress and Long Term Strategy. As you know, the inclusion of the compliance provision that would require Arkansas subject-to-BART sources to install and operate BART no later than six years after the effective date of the State's regulation was not approved by EPA and should be enforced as written in the Clean Air Act under Sec. 169A (g)(4).¹

We would like to request that ADEQ summarize, on a facility-by-facility basis, levels of controls considered, final control selected, and information on how the "five factors" were considered in making its decisions. Detailed information can be placed in an Appendix, but BART information submitted by the owner or operator of a pollutant source is not a substitute for the State decision processes.

We request that ADEQ look at our previous comments on the Draft SIP dated June 6, 2008 as some of these are still pertinent.

The original Reasonable Progress discussion in the Draft SIP had several content deficiencies. It does not appear that ADEQ has made the needed correction. The SIP or the SIP review for the 5-year Regional Haze Progress Report (5-year review) does not identify any procedure to address single sources, or combinations of sources, that are predicted to continue to significantly impact visibility conditions in the future after implementing BART, CSAPR, (Cross State Air Pollution Rule) and any other on-the-books and on-the-way programs. Although the State concludes that additional controls are not necessary, we feel the following areas need further consideration:

- Summarize or offer clarity on what controls the Central Regional Air Planning Association (CENRAP)² Regional Planning Organization (RPO) utilized within Arkansas in their analyses. (See comment letter dated June 6, 2008, Page 7, #17).

¹ "Sec. 169A (g)(4) the term "as expeditiously as practicable" means as expeditiously as practicable but in no event later than five years after the date of approval of a plan revision under this section (or the date of promulgation of such a plan revision in the case of action by the Administrator under section 110(c) for purposes of this section);"

² Central Regional Air Planning Association CENRAP is an organization of states, tribes, federal agencies and other interested parties that identifies regional haze and visibility issues and develops strategies to address them. CENRAP

- A discussion of why model performance evaluation for the base year indicated significant under predictions of visibility impacts from sulfate at the two Class I areas located within Arkansas (See comment letter dated June 6, 2008, page 3, #7), and
- A discussion of the significance of 2002 to 2018 projections of increased point source sulfur emission within Arkansas. Although the model is used in a relative sense, no additional discussion or clarification is provided to address how model performance or model response is adequately addressing issues that may arise from impacts from sulfates, (See comment letter dated June 6, 2008, page 3, #8).
- New Prevention of Significant Deterioration permits (PSDs) that are not represented in the emissions inventory (i.e. John W. Turk and Plum Point II) should be considered as part of the Reasonable Progress Goals (RPG). Table 2.3 appears to have a number of gaps in the data. Please clarify if these sources were considered in the inventory presented.
- The Draft SIP and the 5-year review document omitted the required four factors analysis for establishing the Reasonable Progress Goals. Meeting the uniform rate of progress glide slope does not eliminate the need to analyze the four statutory factors of Reasonable Progress. (See comment letter dated June 6, 2008, page 9, #20).

Again, we wish to express our appreciation for the opportunity to comment on the proposed Regional Haze plan revision. If you have any questions or would like to further discuss or clarify our comments please feel free to contact Judy Logan (501) 321-5341, Mr. Blackwell (479)-964-7200, or Mr. Wagoner (501)-321-5202. We look forward to continuing to work closely with you at improving Arkansas's valuable air resources.

Ms. Teresa Marks
Director,
Arkansas Department of Environmental Quality
5301 Northshore Drive
North Little Rock, AR 72118-5317

Dear Ms. Marks:

On February 25, 2008, the State of Arkansas submitted a draft Regional Haze Rule State implementation plan (SIP), pursuant to the requirements codified in federal rule at 40 CFR 51.308(i)(2), describing its proposal to improve air quality regional haze impacts at mandatory Class I areas across your region. We appreciate the opportunity to work closely with the State through the initial evaluation, development, and, now, subsequent review of this plan. Cooperative efforts such as these ensure that, together, we will continue to make progress toward the Clean Air Act's goal of natural visibility conditions at all of our most pristine National Parks and Wilderness Areas for future generations.

The U.S. Department of Agriculture, U.S. Forest Service, received and has conducted a substantive review of your draft Regional Haze Rule implementation plan, which you are preparing in fulfillment of your requirements under the federal regulations 40 CFR 51.308(i)(2). Please note the U.S. Environmental Protection Agency (EPA) makes the final determination regarding the document's completeness and approval.

As outlined in a letter sent to each State in October, 2006, our review focused on eight basic content areas. The content areas reflect priorities for the Federal Land Manager agencies, and we have enclosed comments associated with these priorities. Note that we have highlighted comments in bold face that discuss what we consider to be major concerns of the proposed SIP that we believe warrant additional consultation prior to final adoption of the Arkansas Regional Haze Plan. The Forest Service air quality staffs stand ready to work with you towards resolution of these issues. We look forward to your response, as per section 40 CFR 51.308(i)(3). For further information, please contact Judith Logan at (501) 321-5341.

Arkansas State Implementation Plan
11/12/2009

Again, we appreciate the opportunity to work closely with the State of Arkansas and compliment you on your hard work and dedication to significant improvement in our nation's air quality values and visibility.

Sincerely,

MILBURN BREWSTER

Forest Service Technical Comments on Arkansas' Department on Environmental Quality (ADEQ) Draft Regional Haze State Implementation Plan (SIP)

Overall Comment

The Forest Service has a significant concern that the information provided in the Arkansas' Draft Regional Haze SIP fails to describe or address content elements required by the Regional Haze Rule. In particular, the State relies on numerous appendices in lieu of sufficient summary descriptions to adequately address the content areas identified by the Act or rule.

Two specific content areas are lacking sufficient analysis, description, or comparison to the mandatory factors identified by the Act and subsequent rules. These are the presentation of Best Available Retrofit Technology (BART) decisions made by Arkansas, as well as the treatment of Reasonable Progress and Long Term Strategy. Detailed discussions of these issues are explained in the technical comments that follow.

We are concerned that the apparent lack of sufficient summary and reasonable progress or analyses of the statutory factors may make this draft un-approvable. The Forest Service respectfully requests that the State of Arkansas reconsider the Draft SIP in its present form before release to the public. We ask that the State review the eight elements identified by the Forest Service letter (October, 2006) and expand its discussion in the document regarding how ADEQ approached, evaluated, and drew conclusions on these important rule elements.

The remaining comments provided here are organized according to the priorities that we presented in our October, 2006, letter. Many of the following comments will also provide direction towards building the narrative of the Draft SIP to satisfy the documentation and content area deficiencies noted above.

Baseline, Natural Conditions, Uniform Rate

1. Sections 5.1 states that baseline visibility conditions for the Caney Creek Wilderness Area was established using three years of IMPROVE data, and notes that this "does not meet EPA completeness criteria for the five year averaging period." Section 6 indicates that the Caney Creek IMPROVE site was installed between 2000 and 2003, which is the reason for not having five years of monitoring data at the time baseline was set. Please note that the Regional Haze Rule requires three of five years for baseline calculations, and thus the Caney Creek monitoring site does have sufficient years of valid data to meet the completeness criterion.
2. Sections 5.1 and 5.2 of the Draft SIP discuss baseline and natural visibility conditions for the Caney Creek and Upper Buffalo Class I areas. One minor discrepancy that we noted was with

Arkansas State Implementation Plan
11/12/2009

the baseline 20% worst B_{cat} Nitrate value in Appendix 5.2, table 5.2a – it should be 13.78 rather than 13.76.

3. Figures 10.2 and 10.4 present a "Uniform Rate of Progress for the Twenty Percent Best Days" for both Arkansas Class I areas. Table 10.2 presents the information from those figures in tabular form. The Regional Haze Rule requires that visibility impairment on the worst 20% days be restored to natural conditions over the 60 year timeframe; however, the Rule requires that at a minimum the cleanest 10% days cannot be degraded. The figures 10.6 and 10.8 showing the Reasonable Progress Goals for the Best Days, which appear in the following section, address the Regional Haze Rule Best-Days goal appropriately. Figures 10.2, 10.4, and table 10.2 should be deleted from the Draft SIP because they are not pertinent to the SIP. In addition, the actual deciview Reasonable Progress Goals for both worst- and best-days at each of the Arkansas Class I areas need to be explicitly stated in the SIP narrative, not just shown in the graphics accompanying the discussion.
4. Generally, Regional Planning Organization (RPO) future projections were based on applying relative response factors (RRF) to the modeled results. However, the Draft SIP does not mention RRFs in conjunction with the future year visibility predictions. Please identify whether "Uniform Rate of Reasonable Progress Glide Paths" presented in section 10.1 of the Draft SIP were produced using actual model outputs or the results of applying a relative response factor. If these numbers were the result of a relative reduction, please provide a discussion in the SIP of how they were generated.

Emission Inventories

5. Section 7.0 – Tables 7.1 and 7.2 list 2002 and 2018 emission estimates by basic source category, respectively. This very brief chapter provides reference to two appendices – the first is a lengthy technical report prepared by a contractor, and the second is a "Short Summary of the 2002 Emission Inventories Methodology Utilized by Arkansas." The chapter then indicates that the 2018 emissions inventory will be further discussed in the next chapter. Chapter 8 covers the modeling assessments conducted for this SIP development, with section 8.4.1 providing a one-paragraph description of the basis for the "2018 base case."

Throughout all of these discussions, there is too much burden placed on the reader to review large reports in the appendices, with no discussion or conclusions provided by ADEQ except for the unsupported numerical data in the chapter 7 tables. For instance, we were unable to determine whether the "2018 Emissions Inventory Summary" presented in Table 7.2 represents the future base case without additional controls, the future projection utilizing CAIR and/or BART controls, or possibly some other future control scenario. This Chapter should identify and describe the differences between the various emissions scenarios that ADEQ employed for its Regional Haze SIP analyses and decisions, including Base/Performance, Typical 2002, Base 2018, and any Alternate 2018, emissions inventories, and how it is utilizing each scenario.

6. There are inconsistent emission discussions starting with section 8.1 leading into section 8.4. Model performance should not use typical base or future emission inventory data. Section 8.3 provides non-related information on emission development for other purposes in the middle of

Arkansas State Implementation Plan
11/12/2009

a performance discussion. No information is provided to describe the performance inventory. Section 8.4 also skips from one topic to another, with discussions of future inventory, typical inventory, and model performance intermingled.

7. Section 8.4.2 presents the results of model performance evaluations for the Arkansas Class I areas. The discussions for Caney Creek and Upper Buffalo suggest significant underestimation of impacts due to sulfur, in the range of 30%-50%. These data are simply stated, but their implications and ADEQ's conclusions based upon the information are not explained. RPO final projections are generally based on relative response factors (RRF) corrections, which allow that, while the model may be "off" in absolute terms, it still responds to increases or decreases in impact. There is no mention of RRFs or appropriate model response analyses.
8. There is significant uncertainty with the future projection of sulfur dioxide emissions from the Electric Generating Utility (EGU) sector. As currently drafted, the SIP projects an overall increase in SO₂ emissions between the baseline and 2018, despite inclusion of BART controls on a significant amount of current emissions. The SIP should commit the State to review and revise emissions projections from 2012 to 2018 as part of a 5-year review required by the regional haze rule. This commitment will assure that the projected improvements represented by the reasonable progress goals set in Section 10 will be achieved. The commitment to review must include a commitment to seek further controls or adjust the reasonable progress goals though a SIP revision should the emissions projections vary substantially from those projected at this time. Those revisions may result in additional improvement in visibility if the current projection of new power generation in Arkansas does not materialize, or if such generation does not yield the expected amount of new emissions.

Section 12 briefly provides a broad commitment to periodic review and revision of the SIP as a whole. The Emission Inventory sections should discuss the uncertainty and then point to the Section 12 commitment as ADEQ's plan of action on that front, and ensure that the statement provided in Section 12 adequately encompasses the scope described in this comment.

9. Section 8.5 presents a short discussion and a few figures about the "2018 Base G C1 Control Strategy" that CENRAP generated. This scenario involved examining the pollution sources within the "areas of influence" of the nearby Class I areas, and assuming that controls would be applied up to a cost of \$5,000/ton level for all such facilities that had a ratio of emissions-to-distance-from-Class-I-area of 5 or more (tons per year/kilometers). Resulting reductions to visibility impacts are described as significant, yet nowhere does the Draft SIP explain whether Arkansas or any other State identified in that scenario, has committed to or will benefit from such an inventory. Thus, we do not understand the context in which ADEQ is discussing the 2018 Base G C1 scenario.

Best Available Retrofit Technology (BART)¹

¹ BART-eligible sources are those sources that have the potential to emit 250 tons or more of a visibility-impairing air pollutant, were not in place or under construction between August 7, 1962 and August 7, 1977, and whose operations fall within one of more of 26 specifically listed source categories. Under CAA section 169A(b)(2)(A), BART is required for any BART-eligible source which "emits any air pollutant that may reasonably be anticipated to cause or contribute to any impairment of visibility in any such area."

Arkansas State Implementation Plan
11/12/2009

10. BART, although partially described, does not offer a sufficient summary of process, source identification, impacts, controls associated with exemption or subsequent determinations. In Arkansas's own statement, the Clean Air Interstate Rule (CAIR) does not constitute sufficient controls to be better than BART. This statement places an additional burden on Arkansas, as compared to a typical CAIR State, to develop and describe a BART process that clearly identifies, evaluates, and decides levels of control or exemption for eligible single sources. The State appears to have conducted much of the necessary steps. However, the SIP document does not adequately describe the analyses and how alternatives associated with controls were considered by the State.

11. Specifically regarding the BART exemption process, we have the following comments:

- a. On page 46, at the end of section 9.2, Arkansas explains that, since it's EGU sources are only required to participate in ozone-season NOx reductions under CAIR, that meeting CAIR requirements does not satisfy BART for these facilities. We concur with this decision. It would be helpful to the reader if this paragraph was relocated earlier in the chapter, prior to BART exemption discussions, to explain why so many EGU emission sources are included in the subsequent BART determination/exemption process in Arkansas.
- b. Section 9.2 does not provide sufficient summary of ADEQ's BART exemption process or results, including the reasons why remaining BART sources were not exempt.
- c. Section 9.2, says that the State will exempt BART-eligible through source-by-source evaluation (that is, in accordance with option 1 listed on page 42). Yet, the text that follows suggests that a cumulative visibility analysis was performed on the six remaining subject-to-BART sources. Readers are referred to Appendix 9.2C for description and methodology. Appendix 9.2C does not include information from ENVIRON or Alpine, nor does it offer another cumulative analysis. It is not clear what purpose or application a cumulative analysis serves for the State.

12. Section 9.4 (together with Appendix 9.2C) of the Draft SIP present a discussion relating to post-control visibility improvement at ten Class 1 areas as a result of BART controls on several subject-to-BART facilities. It demonstrates significant improvement which is to be commended, but also shows that very significant visibility impairment still exists after BART controls are in place. This issue is to be addressed in the Reasonable Progress portion of the Draft SIP. However, some consideration might be given as to whether some of the BART control technology chosen by the sources specifically to satisfy the BART requirements might preclude possibly more effective technology that could have been deployed in an overall more cost-effective manner as part of the Reasonable Progress phase. The ADEQ might determine if a much higher level of control (beyond BART) by a BART source at this time might allow the ADEQ to not require further controls from that particular source as part of its Reasonable Progress determination.

The attachment to this comment document provides source-specific recommendations regarding control technology options that ADEQ should consider for its six "subject-to-BART" sources.

Arkansas State Implementation Plan
 11/12/2009

13. Specifically regarding the Draft SIP's presentation of BART control determinations, we have the following comments:

- a. Section 9.3 is where the Draft SIP should provide a summary of the BART determinations for the Subject-to-BART sources. However, the few paragraphs and tables presented are insufficient. ADEQ should summarize, on a facility-by-facility basis, levels of controls considered, final control selected, and information on how the "five factors" were considered in making its decisions. Detailed information can be placed in an Appendix, but company submitted BART information is not a substitute for State decision processes.
- b. The information presented in the tables 9.3a through 9.3d is difficult to follow. Earlier in this chapter, the BART-eligible units are identified by name, with Facility ID, AFIN, and Unit ID noted (table 9.1). Subsequently, the Subject-to-BART source subset is listed, again by name with Facility ID and Emission Unit descriptions, but no AFIN numbers (table 9.2). But, tables 9.3a thru 9.3d omit the source names, list the units apparently with the AFIN number (but in the column titled "Source and Unit"), and include what appears to be a reference to a State-issued operating permit number that presumably contains the emission limits provided in those tables. It would be very helpful for the tables throughout this chapter to be consistent in the syntax of referencing the specific BART units. We suggest that the tables do include the source names to help those unfamiliar with the syntax of the air pollution source ID listings and ADEQ's permit number assignments.
- c. Tables 9.3a thru 9.3d appear to have some errors, and/or information that may need further explanation:
 - Table 9.3a, sixth data row: we believe that this source's AFIN number should be "30-00011," for the Entergy-Lake Catherine facility, instead of "30-00110." The latter does not appear on the BART-eligible list of Table 9.1. But, note that the unit listed for this entry in table 9.3a, "SN-03 bit" does not match any BART-eligible unit for the Entergy-Lake Catherine facility, per table 9-1; it does match the unit description for this facility in table 9-2.
 - We do not understand the information presented in these tables across the following columns: "Baseline Peak 24-hour Emissions (lb/hr)," "BART Level of Control %," and "Future Peak 24-hour Emission Rate (lb/hr)." The first several entries in table 9.3a, the calculation of Future Peak 24-hour Emission Rate is consistent with applying the listed BART Level of Control to the Baseline Peak 24-hour Emissions values. But, the listings for three units with "0%" control are confusing! The footnote indicates that the BART Level of Control is "only listed if facility is adding controls or taking limits that will reduce emission per BART requirements. Facilities which are not adding controls or using controls which are already installed have a 0% BART control efficiency." Yet, one of these three units shows that, after applying a 0% BART control level, its emission will still be reduced by nearly half. In addition, there are two entries that state the BART Level of Control will be "up to 95%," but that only calculate a Future Peak 24-hour Emission Rate representing approximately 80% control each. Similar confusing data are presented in tables 9.3b (for the four units with 69% NOX BART control), and for the entries of table 9.3c. The single footnote under table 9.3a does not adequately explain the

Arkansas State Implementation Plan
11/12/2009

data that ADEQ includes in these tables. The added discussion of the BART determinations that we recommend earlier in this comment (see paragraph a, above) will help a lot, but ADEQ should ensure that the meaning of the data in the tables is clear to the reader.

- d. Section 9.4 introduces a statistically based test (TTEST in Excel) as a way for the State to evaluate BART control significance. This test or cumulative modeling is not a substitute for the 5 factor analysis.

Area of Influence (AOI)

- 14. The Consultation Plan and associated information that is included as Appendix 10.2 to the Draft SIP contains a general AOI map for the combined Arkansas-Missouri Class I areas, and several assorted graphics for each Class I area of interest. However, the results of these studies, concepts, and graphics, are not presented in the Draft SIP text. They should be integral to the discussions of attribution of regional haze causing pollution, identification of reasonable progress goals, and development of long term strategies for this Regional Haze Plan.

Figures 9.1 and 9.2 of the Draft SIP present geographic representations of Arkansas' BART-eligible and BART-subject sources with relation to the Arkansas and Missouri Class I areas. However, instead of overlaying AOI information, the diagrams use "300 km buffers" about those Class I areas.

In contrast, CENRAP conducted extensive AOI analyses, and produced graphic representations for each of the Class I areas within and near to the CENRAP region. However, the Draft SIP does not provide any of these graphics for the local Class I areas of concern, nor does it discuss any of the work or results from those analyses.

- 15. *Arkansas Sources' Impacts on Out-of-State Class I Areas:* Section 1.2 identifies Class I areas affected by visibility impairing emissions originating from the State of Arkansas. Specifically, two such Class I areas are located within Arkansas (the Caneys Creek and Upper Buffalo Wilderness Areas, both managed by the Forest Service), and two are located in Missouri (the Mingo Wilderness Area managed by FWS, and the Hercules Glades Class I area managed by the Forest Service). Although this section states that emissions from Arkansas are likely to cause or contribute to regional haze in the identified out-of-State areas, little to no consideration is afforded to the Missouri Class I areas and Arkansas sources' impacts to visibility impairment in them, for the remainder of the Draft SIP:

~~Overall, the Draft SIP fails to utilize appropriate Area of Influence (AOI) information generated by CENRAP and the other RPOs in its analyses of both contributions of other States' sources to Arkansas' Class I areas, visibility impairment as well as contributions of Arkansas' sources emissions to out-of-state Class I areas.~~

The documents provided with appendix 10.2 of the Draft SIP include an August 17, 2007, letter from ADEQ Air Division Chief Mike Bates to Oklahoma Department of Environmental Quality (ODEQ) Air Quality Division Director Eddie Terrill. This letter responds to ODEQ's initial consultation meeting regarding the Regional Haze planning for its Wichita Mountains

Arkansas State Implementation Plan
11/12/2009

Wilderness Area. In this letter, Arkansas disagrees with ODEQ's "assertion that sources in Arkansas contribute significantly to an inability to achieve reasonable progress [at Wichita Mountains]." It is unclear whether ODEQ has accepted Arkansas' opinion in this matter. As an additional note, while the discussion in Section 11.3 of Arkansas' Draft SIP (quoted below in comment #19) says that visibility projections for outside-of-Arkansas Class I areas will meet or exceed the uniform rate of progress, this letter to ODEQ indicates that the projections for Wichita Mountains "will not meet the glidepath representing a return to natural conditions by 2064." In addition, one of the BART appendices identifies the Sipsey Wilderness Area (Forest Service managed) in Alabama as potentially being impacted by that source's emissions.

The State should discuss in more detail how analysis of its sources' impact became limited to only the Arkansas and Missouri Class I areas, and why the areas outside Arkansas itself did not appear to be part of the consideration when ADEQ evaluated emission controls for its sources.

16. *Other States' Sources Impacts on Arkansas' Class I areas:* As an example, the data contained within both the Draft CENRAP TSD and ADEQ's Consultation Plan (appendices 8.1 and 10.2 to the Draft SIP, respectively), indicate that the areas of influence that affect the Arkansas and Missouri Class I areas extend across several surrounding States. In fact, the CENRAP "PSAT" source apportionment modeling results for the Upper Buffalo Class I area, show that sulfur emissions from elevated point sources in Illinois, Missouri, Indiana, Kentucky, and the collective states to the east beyond those, are all more significant than Arkansas' sulfate sources in contribution to the 2018 projected 20% worst visibility days. And, for the Caney Creek Wilderness Area, the impact of all pollutant emissions originating in Texas outweighs Arkansas' own impacts to visibility impairment in the 2018 worst 20% projections. The Draft SIP needs to discuss the attribution of haze-causing pollution and the results of ADEQ's consultations with neighboring States regarding achieving Reasonable Progress Goals at its local Class I areas.

Reasonable Progress Goals and Long Term Strategy

17. The Reasonable Progress discussion in the Draft SIP is a major content deficiency. The SIP document does not identify any procedure to address single sources, or combinations of sources, that are predicted to continue to significantly impact visibility conditions in the future after implementing BART, CAIR, and any other on-the-books and on-the-way programs. Although the State concludes that additional controls are not necessary, Arkansas does not summarize or offer any level of clarity on what controls the CENRAP² Regional Planning Organization (RPO) utilized within Arkansas in their analyses. Model evaluation at the two Class I areas located within Arkansas indicates significant under-predictions of visibility impacts with regard to sulfates, and fails to address any significance of 2002 to 2018 projections of increased point source sulfur emission within Arkansas. Although the model is used in a relative sense, no additional discussion or clarification is provided to address how model performance or model response is

² Central Regional Air Planning Association CENRAP is an organization of states, tribes, federal agencies and other interested parties that identifies regional haze and visibility issues and develops strategies to address them. CENRAP is one of the five Regional Planning Organizations RPOs across the U.S. and includes the states and tribal areas of Nebraska, Kansas, Oklahoma, Texas, Minnesota, Iowa, Missouri, Arkansas, and Louisiana.

Arkansas State Implementation Plan
11/12/2009

adequately addressing issues that may arise from impacts from sulfates. We are also concerned with the number of new PSDs that do not seem to be represented in the emissions inventory (i.e. John W. Turk and Plum Point II). It is going to be extremely difficult if not impossible to meet the RPG while adding new sources to the mix.

CENRAP (as well as the VISTAS RPO in the southeast United States) produced analyses to assist States in identifying geographic areas which may represent the source area most likely for a State to target additional controls for Reasonable Progress consideration. The State appears to have disregarded these supporting documents, and in spite of increasing sulfur emissions, did not discuss whether additional BART (beyond presumptive levels) for sources subject to BART, or other controls at non-BART pollution sources, may constitute a reasonable control. The SIP does not address the four statutory factors when making decisions to control or not control additional sources. Analysis of all control alternatives of potentially significant sources is necessary in order to fully evaluate reasonableness when looking at the factors. Although it is possible for the State to arrive at the same conclusions as presented in the draft SIP, there is no evidence that the State had sufficient information to conclude as to the reasonableness of its strategy to achieve the 2018 milestones.

18. In Section 10, titled "Reasonable Progress Goals" the State does not specifically declare reasonable progress goals, in-deciview, for the year 2018. Table 10.3, on page 59, speaks to an amount of improvement for the most impaired days from baseline conditions. The reasonable progress goals should be clearly stated as the projected 2018 average of the 20 percent most impaired days and as the 20 percent least impaired days. These numbers are included in Figures 10.5 through 10.8 but are not declared in the text. Please revise the text in Section 10 to clarify ADEQ's choice of the 2018 reasonable progress goal and revise Table 10.3 to include a column indicating the goals for the least impaired days, as required by the regional haze rule.

19. Section 11.3 is very confusing, it switches back and forth between impacts at Arkansas' Class I areas and impacts beyond the State's borders, and declares that otherwise unspecified emission reductions will achieve the RPG goals across seemingly both geographic divisions of Class I areas.

The section opens with a paragraph indicating that the section will cover Arkansas' demonstrating that its SIP includes "all measure as necessary to obtain its fair share of emission reductions needed to meet [reasonable progress goals] in other Class I areas." The next paragraph identifies the categories of technical material that Arkansas relied upon to conduct a gross identification of other states with emissions that influence Arkansas Class I areas, says that those identified States were included in the consultation process, and then asserts that "CENRAP-modeled visibility projections indicate that the emission reductions planned for these states are sufficient to achieve the [reasonable progress goals] for all Class I areas located in Arkansas and Missouri." Nowhere are the emission reductions further described or quantified. The next paragraph indicates that, since CENRAP and ADEQ analysis show that visibility projections for the Class I areas outside Arkansas and Missouri "will all be able to demonstrate a better than uniform rate of progress through the

Arkansas State Implementation Plan
11/12/2009

implementation of existing and forthcoming State and federal emission reduction programs... The emission reductions described elsewhere herein are sufficient to constitute a fair share of emission reductions needed to meet RPGs in affected Class I areas."

This is the bulk of Arkansas' evaluation of its Long Term Strategy to achieve Reasonable Progress towards visibility improvement both for its Class I areas and for those outside of the State to which Arkansas source emissions contribute. This discussion, both independently and in conjunction with the complete Draft SIP narrative, fails to provide the reader with an understanding of the causes of visibility impairment at either Arkansas' Class I areas or those in nearby States, the control strategies that were considered and levels of control that ADEQ decided to require for this SIP, or the anticipated results of those controls.

20. At the beginning of Section 10 of the Draft SIP, ADEQ outlines the four statutory factors that each State must consider in setting its Reasonable Progress Goals. These factors are intended to be applied holistically, across all contributing sources of visibility impairing pollutants, to inform the decision being made by the State. However, the remainder of the chapter never connects back to the four statutory factors, and in fact points to appendix 10.1, "Analysis of Control Strategies and Determination of Reasonable Progress Goals," which argues that meeting the uniform rate of progress glide slope obviates any need for analyzing the four statutory factors for Reasonable Progress. Thus, the Draft SIP omits the required four-factor analysis for establishing the Reasonable Progress Goals.

21. In Section 11.4.1.6, the Draft SIP identifies "source retirement and replacement," saying that: "retirement and replacement will be managed in conformance with existing SIP requirements pertaining to PSD and New Source Review. Source retirement and replacement will be tracked through on-going point source inventories." Please elaborate on how the PSD and NSR permitting programs will be utilized by ADEQ as part of its Long Term Strategy for meeting Reasonable Progress Goals.

Fire

22. The Arkansas Smoke Management Plan (SMP) and the summary discussion in section 11.4.1.8 of the Draft SIP properly identify Class I areas as being smoke-sensitive, and the SMP instructs prescribed burners to apply the appropriate smoke management techniques to minimize impacts. Overall, this is one of the best presentations of fire-emission-related Regional Haze considerations that we have seen to date.

23. We recommend that ADEQ ensure that its Regional Haze SIP refers to the Arkansas SMP in a way that does not require SIP updates each time the SMP is updated. Also, please indicate whether Arkansas intends to "certify" its SMP as provided for by the 1998 EPA Interim Air Quality Policy on Wildland and Prescribed Fire.

Regional Consistency

24. Arkansas is situated geographically at the boundary between three multi-state Regional Planning Organizations (RPO): CENRAP running along the west of the Mississippi River

ATTACHMENT

**U.S. Forest Service Comments Regarding
Best Available Retrofit Technology (BART) Determinations
Arkansas Draft Regional Haze Rule State Implementation Plan**

April 1, 2008

This document is an attachment to the U.S. Forest Service (FS) comments on the Draft Regional Haze State Implementation Plan prepared by Arkansas and received by the FS on February 25, 2008. It provides source-specific recommendations regarding the Best Available Retrofit Technology (BART) determinations contained within that package.

Entergy Services, Inc. BART Determination for the Lake Catherine Plant

Table 9.2 of the ADEQ RH SIP shows that the Lake Catherine Plant is a subject-to-BART source, but Tables 9.3 a-d do not include emission reductions from the 2002 Baselines for this source. Either the data for the Plant should be included or a reason for their exclusion should be noted.

The low 10% plant utilization rate causes any capital equipment alternative to magnify the cost per ton or incremental cost per ton, thus eliminating standard alternatives available to other BART determinations. For this reason it is important to impose strict emission limitations commensurate with 10% plant utilization in the plant's permit.

Section 3.1 of the BART determination proposes that boiler tuning, BOOS and IFGR is NO_x BART for gas firing. The addition of overfire air to the above three controls results in an annual cost effectiveness of \$1,700 per ton for NO_x control and a \$1.3 million cost per deciview. This is not an unreasonable cost for BART and should be considered. The value of this step would be to decrease the visibility impact from 0.56 deciviews to 0.34 deciviews.

The Arkansas Regional Haze SIP acknowledges that BART requirements are applicable requirements of the Clean Air Act and they will be included as title V permit conditions. It would be desirable that systems be installed to automatically monitor and trim oxygen and fuels for peak performance. Emission limits reflecting the above BART should be met on a continuous basis. For a discussion of this topic please refer to EPA's BART Guidelines.³

³ See 40-CFR Part 51, Appendix Y. The U.S. Environmental Protection Agency finalized its BART Guidelines on June 15, 2005, and published the preamble and final rule text in the Federal Register on July 6, 2005. The rulemaking action added Appendix Y to Part 51, titled "Guidelines for BART Determinations Under the Regional Haze Rule." See Section V.

The costs of alternatives were stated by Entergy, but there was no documentation or a detailed break-out of the costs. The basis for equipment cost estimates also should be documented either with data supplied by an equipment vendor (i.e., budget estimates or bids) or by a referenced source (such as the EPA OAQPS Control Cost Manual), where possible.⁴ A discussion of amortization of costs is presented, but the actual amortization factors are not given.

Entergy Services, Inc. BART Determination for the White Bluff Steam Electric Station

Entergy proposes to install SO₂ and NO_x control equipment that will meet the presumptive requirements of the EPA's BART Guidelines. The Arkansas Regional Haze SIP acknowledges that BART requirements are applicable requirements of the Clean Air Act and they will be included as Title V operating permit conditions. Emission limits such as BART must be met on a continuous basis. Although this provision does not necessarily require the use of continuous emissions monitoring (CEMs), it is important that sources employ techniques that ensure compliance on a continuous basis. The only such reference found in the BART determination was in Section 3.1 relating to boiler tuning, so further discussion of meeting emission limits on a continuous basis should be included. For a discussion of this topic please refer to EPA's BART Guidelines.⁵

Though presumptive BART is met for both NO_x and SO₂ using the proposed emission controls, Table 5-1 shows that the White Bluff Station will still "cause" visibility impairment at the Caney Creek Class I area. In considering its Long Term Strategy in the Regional Haze SIP for Caney Creek, the State should hold discussions at this time with the source to determine the possible need for additional future controls. Entergy might consider an altered mix of capital expenditures for emission control at this time given that information.

Domtar Industries Inc. BART Determination for the Ashdown Mill

The costs of the NO_x control alternatives of Low NO_x (LNB) burners and Overfire Air (OFA) for boilers #1 and #2 are presented in Table 4-3 and the conclusion is that the average cost per ton of NO_x control is cost-prohibitive. Costs in Table 4-3 are derived from total costs shown in Appendix B. The total costs from Appendix B and the Total Annualized Cost for LNB and OFA shown in Table 4-3 seem excessive. For example, the total capital costs are not generally consistent with those presented in Appendix E of the National Council for Air and Stream Improvement (NCA SI) paper entitled, "NO_x Control in Forest Products Industry Boilers: A Review of Technologies, Costs, and Industry Experience."⁶ Also, the amortization factors of 5% interest and 10 year life are not consistent with the 7% and 15 year life required by the OAQPS

⁴ See EPA's BART Guidelines, Section IV.D.Step 4.

⁵ See EPA's BART Guidelines, Section V.

⁶ Report by the National Council for Air and Stream Improvement entitled, "NO_x Control in Forest Products Industry Boilers: A Review of Technologies, Costs, and Industry Experience", Special Report No. 03-04, August 2003, by: Arun V. Sameshwar, Ph.D., and Ashok K. Jain, NCA SI Southern Regional Center, Gainesville, Florida, Appendix E.

Control Cost Manual.⁷ The basis for equipment cost estimates should be documented either with data supplied by an equipment vendor (i.e., budget estimates or bids) or by a referenced source (such as the EPA OAQPS Control Cost Manual, where possible.⁸ More realistic figures may make LNB and OFA cost-effective BART alternatives.

Table 4-7 shows that the Ashdown Mill will still "cause" visibility impairment at the Caney Creek Class I area after implementation of controls. In considering its Long Term Strategy in the Regional Haze SIP for Caney Creek, the State should hold discussions at this time with sources to determine the need for additional future controls. The sources might consider an altered mix of capital expenditures for emission control at this time given that information.

Arkansas Electric Cooperative Corporation BART Determination for Bailey and McClellan Stations

Pages 2 and 5 state that because pollutant-specific modeling for these facilities showed that NO_x did not cause or contribute to visibility impacts at any Class I areas and since the PM impact was less than NO_x, only SO₂ BART controls would be considered. This is not correct. The EPA's BART Guidelines describe a state-wide-cumulative, pollutant-by-pollutant modeling analysis of all BART-eligible sources.⁹ If such an analysis shows that NO_x for example, does not cause or contribute to visibility impairment, you may conclude that none of the BART-eligible sources in the state are subject to BART for NO_x. However, such an exemption is not derived from the modeling of a single, or even two sources. Therefore, NO_x and PM should have been included in the BART determinations for the Bailey and McClellan Stations.

The SO₂ BART determination concluded that "a lower-sulfur fuel oil" should be considered as BART. Only a footnote to a table indicated that 1% low sulfur fuel oil was used for modeling the post-control scenario. First, the BART determination should have considered 1% sulfur fuel oil along with other ultra-low sulfur fuel oils in the analysis and then should have shown the economic viability of one fuel over the others. This is especially true since the table showing post-control modeling results for the Bailey Plant for 2002 showed 8 days above 0.5 dV visibility impact at Mingo using 1% sulfur fuel oil. This indicates that the chosen BART for the Bailey Plant still "contributes" to visibility impairment at Mingo. Serious consideration should be given to a lower-sulfur fuel. Second, a more definitive description of the chosen fuel should be stated and ADEQ should make it an enforceable permit condition.

Other BART determinations reviewed by the RS contain more supporting documentation than the subject determination in terms of exemption modeling data (before and after controls), scrubber cost estimates, fuel alternatives and the Section 4.4 claim that "... high capital cost control of the scrubber alternative (emphasis added) ... may cause the retirement of these units."

⁷ U. S. Environmental Protection Agency, Office of Air Quality Planning and Standards, OAQPS Control Cost Manual, Fifth Edition, February 1996, EPA 453/B-96-001.

⁸ See EPA's BART Guidelines, Section IV.D.Step 4.a.5.

⁹ See EPA's BART Guidelines, Section III.A.3.Option 3.

The EPA's BART Guidelines describe an analysis to be followed when viability of continued plant operations is an issue.¹⁰

Finally, since the Bailey plant is currently operated at only 20% of capacity and since the use of 1% sulfur fuel oil results in a continuing "contribution" to visibility impairment at Mingo; ADEQ should place a permit condition on the facility to operate with emission limitations reflecting 20% of capacity. Of course, if technology with higher emissions control efficiency can be provided, then such a permit condition can be relaxed.

AEP Southwestern Electric Power Company (SWEPCO) BART Discussions for the Flint Creek Power Plant

A two-page letter from SWEPCO to the Arkansas Department of Environmental Quality, dated October 26, 2006, is the only information we have available regarding the subject Plant's effort to meet BART. The RH SIP and/or appendices should contain all of the BART-related data so that they are available to third-party reviewers.

With reference to Item 1, electrostatic precipitators may be BART for particulate matter (PM), but not for the reason cited. For BART purposes it is inappropriate for a source to model for a single pollutant (e.g., PM) and if that single pollutant does not impact a Class I area by more than the threshold, to eliminate emission units which emit that pollutant from BART for that pollutant. As discussed in EPA's BART Guidelines, the total emissions (SO₂, NO_x, and PM) from all emission units from the source should be summed.¹¹ If the potential to emit of any single visibility impairing pollutant exceeds 250 tons per year then that collection of emissions units is a BART-eligible source. Each emission unit is then subject to a BART review for each of the visibility impairing pollutants. Thus, a BART review should have occurred for the emission units that feed the electrostatic precipitators (ESP). It is acknowledged that on a cost basis, it is likely that no other control equipment would be required other than possibly adjustments to the ESPs.

Item 2 of the letter is not clear as to whether control equipment is already functioning at the presumptive limits of 0.15 lbs/mmBTU for SO₂ and 0.23 lbs/mmBTU for NO_x or whether such equipment is proposed to be added to meet BART. The record should contain information that describes the control equipment that is already or will be installed, along with the data that demonstrates how it is deemed to meet BART. If BART is met by the *current* plant configuration then Item 3 referring to "post-control" CALPIBF modeling should not show visibility improvements.

Item 3 of the letter seems to imply (but does not state) that visibility impairment still exists at one or more Class I areas. In considering its Long Term Strategy in the Regional Haze SIP, the State should hold discussions at this time with sources to determine the need for additional future controls. The sources might consider an altered mix of capital expenditures for emission control at this time given that info

Branch of Air Quality

7333 W. Jefferson Ave., Suite 375

Lakewood, CO 80235-2017

In Reply Refer To:
FWS/ANRS-NRCP-AQ/

June 27, 2014

Mr. Mike Bates, Chief
Air Division
Arkansas Department of Environmental Quality
5301 Northshore Drive
North Little Rock, Arkansas 72118-5317

Dear Mr. Bates:

On April 21, 2014, the State of Arkansas provided a draft 5-year progress report for the State's Regional Haze State Implementation Plan (SIP). Overall, the draft included several of the necessary elements and information needed to adequately address regional haze progress. However, we do not feel that a comprehensive review can be conducted prior to the State completing the outstanding core elements of the SIP. At this time, we feel that additional information is necessary prior to concurring with the State's "negative declaration". We welcome further consultation regarding the following concerns:

- Critical core elements of the State's Regional Haze Rule SIP are not approved and therefore cannot be evaluated. Elements include the evaluation and determination of Best Available Retrofit Technology (BART) eligible sources, implementation of additional control technologies related to BART, and the establishment of Reasonable Progress Goals for Class I areas within State boundaries.
- Much of the report indicates emission growth through the year 2011, but then predicts significant emission reductions by year 2018. We are unable to see how the State will accomplish these significant emission reductions, and the report provides no explanation.
- Given the general rise in Arkansas' air pollution emissions through 2011 for most categories, the report does not explain why visibility impacts are improving at the State's Class I areas.
- The report declares that emissions generated within the State of Arkansas are not significantly impacting Class I areas located in nearby States, but it does not provide supporting information or explanation to substantiate the claim.

Mr. Bates, page 2

This letter acknowledges that the U.S. Department of Interior, U.S. Fish and Wildlife Service, has conducted a review of the submitted draft 5-year progress report for your Regional Haze SIP. Please note, that only the U.S. Environmental Protection Agency (EPA) can make a final determination regarding the document's completeness and, therefore, ability to receive federal approval from EPA.

We appreciate the opportunity to review your draft Regional Haze SIP 5-year progress report and look forward to continuing consultations as you pursue approval of the original SIP and this subsequent progress report. If you have questions of concerns, please contact Tim Allen at (303) 914-3802. We appreciate your hard work and dedication to the significant improvement in our nation's air quality related values and visibility.

Sincerely,

A handwritten signature in cursive script that reads "Catherine Collins". The signature is written in black ink and is positioned above the printed name and title.

Catherine Collins

Federal Land Manager Consultation

As required by the federal Regional Haze Rule (40 C.F.R. § 51.308), the Arkansas Department of Environmental Quality (ADEQ, Department) prepared and submitted for review by regional Federal Land Managers (FLMs) a draft document titled “State Implementation Plan Review for the Five-Year Regional Haze Progress Report.” Comments submitted by the FLMs are addressed here. Copies of the FLMs comment letters are included in this appendix. FLMs comments were received from:

- United States Department of Agriculture – Forest Service - Ouachita National Forest,
- United States Department of the Interior – Fish and Wildlife Service, and
- United States Department of the Interior – National Park Service.

On September 23, 2008, the ADEQ submitted an initial Regional Haze State Implementation Plan (SIP) to the Environmental Protection Agency (EPA). On March 12, 2012, the Environmental Protection Agency published a Final Rule that partially approved and partially disapproved the 2008 Arkansas Regional Haze SIP (2008 Arkansas RH SIP).

The Regional Haze Rule requires states to “submit a report to the Administrator every five years evaluating progress towards the reasonable progress goal for each mandatory Class I Federal area located within the State and in each mandatory Class I Federal area located outside the State which may be affected by emissions from within the State.” The required elements of this five-year review, which states must submit five years following the initial Regional Haze SIP submission, are described at 40 C.F.R. § 51.308(g).

The five-year Regional Haze Progress Report (five-year RHPR) also provides an opportunity for public input on the state and the EPA’s assessment of whether the approved regional haze SIP is being implemented appropriately and whether reasonable visibility progress is being achieved consistent with the projected visibility improvement in the SIP. As of July 2014, ADEQ has been unable to fully respond to the EPA with information sufficient to address those disapproved elements of the 2008 Arkansas RH SIP. The Department has been working with the EPA and affected sources towards fulfilling EPA’s requirements for an approvable SIP. Therefore, this required five-year RHPR cannot at this time fully address the goals and implementation measures that the State of Arkansas originally identified as appropriate, but which are disapproved by EPA.

All comments submitted by FLMs are addressed herein. However, ADEQ is currently unable to provide the FLMs with some of the requested information because the comments are either not relevant to this progress report or ADEQ has been continuing to work on the disapproved elements of the 2008 Arkansas RH SIP with EPA and affected sources and cannot provide

further information on this report. In this document, the responses to specific comments that are affected by the ultimate resolution of the EPAs' partial disapproval are identified. A response to these comments would serve no useful regulatory purpose at this time. ADEQ has identified one Comment from FLMs that addresses portions of the Arkansas five-year RHPR draft that needs revisions.

**United States Department of Agriculture – Forest Service (FS) - Ouachita National Forest
Comments**

Submitted by Norman Wagoner and Reggie Blackwell, Forest Supervisors

Comment 1: FS had several areas of concern in the Arkansas 2008 Regional Haze SIP (2008 Arkansas RH SIP) that they still would like to bring forward, specifically how the BART decisions are being handled as the treatment of Reasonable Progress and Long Term Strategy. FS requests ADEQ to summarize, on a facility-by-facility basis, levels of controls considered, final control selected, and information on how the "five factors" were considered in making its decisions.

Response: Any concerns that the FS has with regard to the 2008 Arkansas RH SIP, for the purposes of this five-year RHPR, are moot in view of the previous partial approval / partial disapproval action issued by EPA on March 12, 2012. The majority of the BART determinations as well as Reasonable Progress Goals and Long Term Strategy submitted in the 2008 Arkansas RH SIP were disapproved by EPA. Work with EPA and the affected facilities continue in an effort to revise the disapproved portions of the 2008 Arkansas RH SIP. Attempting to address such matters in this five-year RHPR would be premature.

No revisions to the final report are necessary due to this Comment.

Comment 2: FS requests ADEQ to look at their previous comments on the draft SIP dated June 6, 2008, as some of those comments are still pertinent. The Reasonable Progress discussion in the 2008 Arkansas RH draft SIP had several content deficiencies and it does not appear to FS that ADEQ has made the needed corrections. The five-year RHPR draft does not identify any procedure to address single sources, or combinations of sources, that are predicted to continue to significantly impact visibility conditions in the future after implementing BART, CSAPR, and any other on-the-books and on-the-way programs.

Response: Comments previously submitted with regard to the 2008 Arkansas RH SIP have been taken into consideration. ADEQ is working closely with EPA to resolve any issues that remain after the partial approval and partial disapproval of the 2008 Arkansas RH SIP.

No revisions to the final report are necessary due to this Comment.

Comment 3: FS does not agree with Arkansas's conclusion that additional controls are not necessary and points out the following areas that need further consideration:

- a) Clarification on what controls the Central Regional Air Planning Association (CENRAP) Regional Planning Organization (RTO) utilized within Arkansas in their analysis (see comment letter dated June 6, 2008, p.7 #17);
- b) A discussion of why model performance evaluation for the base year indicated significant under predictions of visibility impacts from sulfate at the two Class I areas located within Arkansas (see FS comment letter dated June 6, 2008, p. 3 #7); and
- c) A discussion of significance of 2002 to 2018 projections of increased point source sulfur emission within Arkansas. Although the model is used in a relative sense, no additional discussion or clarification is provided to address how model performance or model response is adequately addressing issues that may arise from impacts from sulfates (see comment letter dated June 6, 2008, p.3 #8).

Response: These comments are based on the content of the 2008 Arkansas RH SIP submittal and are not relevant to the five-year review.

No revisions to the final report are necessary due to this comment.

Comment 4: FS states that new Prevention of Significant Deterioration (PSD) permits that are not represented in the emissions inventory (i.e. John W. Turk and Plum Point II) should be considered as part of the Reasonable Progress Goals (RPG). Table 2.3 appears to have a number of gaps in the data. FS requests clarification if these sources were considered in the inventory presented.

Response: The RPGs were established in 2008. The CENRAP modeling inventory did not include emissions from these facilities as they were not permitted at that time. The five-year review does not require revision to the previously established RPGs. Emissions from the John W. Turk and Plum Point facilities are included in current inventories and subject to consideration when establishing any future additional control strategies that might be required to maintain reasonable progress. To date, the RPGs established and committed to by Arkansas have been met.

No revisions to the final report are necessary due to this comment.

Comment 5: FS states that the draft 2008 Arkansas RH SIP and the draft RHPR omitted the required four-factor analysis for establishing the RPG. Meeting the uniform rate of progress glide slope does not eliminate the need to analyze the four statutory factors or Reasonable Progress. (See comment letter dated June 6, 2008, p.9 #20.)

Response: A four-factor analysis is not required for the five-year RHPR. The inadequacy of the four-factor analysis is an element of the EPA's partial disapproval of the 2008 Arkansas RH SIP and is under consideration by both ADEQ and EPA Region 6.

No revisions to the final report are necessary due to this Comment.

United States Department of the Interior, Fish and Wildlife Service (FWS) Comments

Submitted by Catherine Collins, Branch of Air Quality

Comment 1: FWS expresses that additional information to the Arkansas five-year RHPR draft is necessary for them to concur with the State's "negative declaration."

Response: Ultimate approval of the 2008 Arkansas RH SIP or supplemental SIP revision, or the possibility of new requirements in the form of a Federal Implementation Plan (FIP), will result in more certainty regarding what is considered to be a reasonable rate of progress. The current negative declaration is supported by evidence that visibility in the affected Class I areas is improving.

No revisions to the final report are necessary due to this Comment.

Comment 2: FWS believes that the critical core elements of the 2008 Arkansas RH SIP are not approved and therefore cannot be evaluated. Elements include the evaluation and determination of best available retrofit technology (BART) eligible sources, implementation of additional control technologies related to BART, and the establishment of Reasonable Progress Goals and a Long-Term Strategy for Class I areas within the State boundaries.

Response: FWS correctly states that unapproved elements of the SIP cannot be readily evaluated. Despite the disapproved portions of the 2008 Arkansas RH SIP, visibility is improving in the affected Class I areas. As of September 2014, ADEQ is still working with EPA and affected BART sources for an approvable RH SIP.

No revisions to the final report are necessary due to this Comment.

Comment 3: FWS states that much of the Arkansas five-year RH Progress Report draft indicates emission growth through the year 2011, but then predicts significant emission reductions by the year 2018. FWS is unable to see how the State will accomplish emission reductions as the draft report does not provide an explanation.

Response: The documentation for 2018 emissions is contained in the 2008 Arkansas RH SIP. Expected emission reductions from BART sources have not been achieved to date. Implementation of BART controls at affected facilities has been delayed by the federal review that resulted in a partial disapproval of the 2008 Arkansas RH SIP. BART reductions at least as stringent as those described in the SIP will be recognized at a future date yet to be determined. Other federal measures will also result in future emission reductions.

No revisions to the final report are necessary due to this Comment.

Comment 4: FWS states that, given the general rise of Arkansas's air pollution emissions through 2011, for most categories, the draft report does not explain why visibility impacts are improving at the State's Class I areas.

Response: The many possible causes for improvement at affected Class I areas cannot be readily determined. Emission reductions achieved through other state and federal programs may account for some of the observed improvement.

No revisions to the final report are necessary due to this Comment.

Comment 5: FWS points out that the draft report declares that emissions generated within the State of Arkansas are not significantly impacting Class I areas located nearby states, but it does not provide supporting information or explanation to substantiate the claim.

Response: ADEQ does not find this declaration within the five-year RHPR. At the top of p.5, ADEQ describes the EPA determination that “Arkansas did not show that the strategy will adequately achieve the RPGs set by Arkansas and by other nearby states.”

At this time, all Class I areas identified as affected by Arkansas sources are meeting the RPGs that were established by the States. Regarding SIP elements and strategies, the report does state that “based upon relevant data (i.e. projected emissions and modeling results) they are sufficient to enable Arkansas and other states with Class I areas affected by emissions from Arkansas to meet all established reasonable progress goals. This appears to be the statement that FWS has misinterpreted.

No revisions to the final report are necessary due to this Comment.

United States Department of the Interior, National Park Service (NPS) Comments

Submitted by Susan Johnson, Air Resources Division, Chief Policy, Planning and Permit Review Branch.

Comment 1: In Chapter 2.1, the description of pollutant contributions to haze on the 20% worst days at Caney Creek and Upper Buffalo Wilderness Areas is good. Figures 2.1 and 2.2 demonstrate that sulfate is the largest contributor to haze of the 20% worst days. Figure 2.3 demonstrates that Electric Generating Units (EGU) and non-EGU point sources are the largest contributors to sulfur dioxide (SO₂) emissions in Arkansas. Therefore, NPS would expect Arkansas to concentrate on reducing point source SO₂ emissions in the long-term strategy.

Response: ADEQ will take actions to make necessary reductions to haze precursors based on the ability to make a demonstrable improvement in haze-related air quality values. SO₂ reductions will be achieved when BART sources are required to reduce SO₂. Other SO₂ reductions will be achieved through implementation of the SO₂ NAAQS, federal Tier III gasoline standards, New Source Performance Standards, and Emission Guidelines for existing facilities. Arkansas will continue to evaluate overall SO₂ emissions in an effort to determine which non-BART sources to consider for additional controls that might be needed to continue to meet the RPGs that have been established for Arkansas.

No revisions to the final report are necessary due to this Comment.

Comment 2: In Chapter 3.1, Table 3.1 indicates that annual emissions of SO₂ from EGU in Arkansas actually increased between 2002 and 2011, while nitrogen oxide (NO_x) emissions decreased slightly. No information is presented about expected emissions reductions from existing EGU between 2011 and 2018 to support the 2018 emissions projections in Table 5.1. The information presented does not demonstrate reasonable progress in reducing point source emissions. NPS requests that ADEQ identify any source specific controls planned and CAIR or CSAPR caps that have yet to be met that would require controls on these sources.

Response: The emissions presented in Table 3.1 are historic. No point-source emission reductions associated with the Regional Haze Rule have been realized to date. The 2018 projections contained in Table 5.1 are from the future-year inventory developed by the Central Regional Air Planning Association (CENRAP). Arkansas developed RPGs that included specific emission reduction requirements for BART sources. Because EPA has not yet approved the 2008 Arkansas RH SIP in its entirety, these reductions have not yet been realized. Any source-specific control associated with the implementation of CAIR or CSAPR caps are, or will be, reflected in annual emission inventories.

No revisions to the final report are necessary due to this Comment.

Comment 3: In Chapter 5, there is a typo in the sentence on top of page 50: Tables 5.2, 5.3, and 5.4 compare 2002 and 2011 emissions, not 2018 emissions. NPS recognizes that emissions from area, non-road, and on-road sectors are calculated by EPA. NPS concerns focus on point EGU and non-EGU facilities that are directly permitted by Arkansas and the lack of information supporting 2018 emissions projections.

Response: The sentence at the top of page 50 has been revised to correctly identify the information contained in Table 5.2, Table 5.3 and Table 5.4. The documentation for 2018 emission projections is included in Appendix 7.2-E of the 2008 Arkansas RH SIP submittal.

Comment 4: In Chapter 7, NPS states that in 2012, EPA disapproved Arkansas's BART determinations and reasonable progress goals for 2018. Arkansas has not yet corrected the deficiencies in the 2008 SIP. Arkansas's five-year Progress Report draft addresses goals that have been disapproved.

Response: The progress goals that Arkansas identified in the 2008 Arkansas RH SIP submittal are based on emission reductions that were identified and modeled on a regional scale. Without re-conducting or otherwise updating the regional-scale modeling effort that was conducted by CENRAP, it is not possible to establish new progress goals. Arkansas is satisfied that its previously identified RPGs are currently being met regardless of the fact that BART controls have yet to be implemented. Having a regulatory requirement to submit a progress report, regardless of whether or not the original SIP submittal has been approved in its entirety by the EPA is problematic; however, ADEQ is attempting to meet that requirement notwithstanding partial disapproval. Goals other than those already disapproved have not been established at this time. As of this date, ADEQ is uncertain what EPA might accept as RPGs.

No revisions to the final report are necessary due to this Comment.

Comment 5: In Chapter 7, Arkansas commits on page 50 to work with EPA as it performs the required four-factor analyses. NPS asks that Arkansas also consult with the affected FLMs.

Response: The referenced commitment is expressed in the fifth paragraph on page 55. There is no regulatory requirement or express need to consult FLMs in the development of a four-factor analysis.

No revisions to the final report are necessary due to this Comment.

Comment 6: In Chapter 7, Arkansas has not demonstrated that it is reducing emissions contributing to visibility impairment at Class I areas in neighboring states. Section 7.4 does not explain why Hercules Glade and Mingo in Missouri were the only Class I areas reviewed. Arkansas should cite the CENRAP source apportionment analyses that show the contribution of Arkansas point, area, and mobile sources at neighboring Class I areas, compared to sources in other states.

Response: The Arkansas point source emission reductions envisioned in the 2008 Arkansas RH SIP have not been implemented as of this date. No additional assessment is ongoing at this time. Visibility impairment in affected out-of-state Class I areas has improved. The Class I areas addressed in this five-year review are those identified in the 2008 Arkansas RH SIP and approved by the EPA.

No revisions to the final report are necessary due to this Comment.

Comment 7: NPS disagrees with Arkansas's conclusion that no additional actions are needed as part of this five-year review. NPS encourages Arkansas to complete revisions to the 2008 Arkansas RH SIP before requesting EPA approval of the five-year RHPR.

Response: The Regional Haze Rule requires submission of a progress report within five years of the original submittal of a Regional Haze SIP. Whether or not the submitted SIP has been approved does not alter this requirement. Additional actions to be taken will be established upon approval of the 2008 Arkansas RH SIP or through federal action in the form of a FIP.

No revisions to the final report are necessary due to this Comment.

Comment 8: NPS states that while the Arkansas five-year RHPR draft demonstrates that visibility is improving at Class I areas in Arkansas and Missouri, there is no demonstration that Arkansas is implementing all the reasonable control measures necessary to meet the 2018 reasonable progress goals for Class I areas in Arkansas and neighboring states.

Response: The most recent assessment of visibility conditions in affected Class I areas in Arkansas and Missouri shows that RPGs established by Arkansas in the 2008 RH SIP are being met. ADEQ anticipates that as BART controls are established and implemented in Arkansas, additional progress will be demonstrated.

No revisions to the final report are necessary due to this Comment.

Comment 9: NPS states that Arkansas has not revised the 2008 Arkansas RH SIP to resolve the deficiencies identified by EPA, in the disapproved portions of the SIP, in March 2012.

Therefore, NPS does not agree with Arkansas's conclusion that the requirements of 40 C.F.R. § 51.308(g) have been met nor that they can support Arkansas's determination that no further actions are required.

Response: ADEQ acknowledges that the disapproved portions of the 2008 Arkansas RH SIP have resulted in a situation where less than desired progress can be achieved at this time. Resolution of the deficiencies identified by the EPA is underway. 40 C.F.R. § 51.308(g) requires only a periodic progress report. ADEQ disagrees with the assertion that the required elements described in 40 CFR 51.308(g) have not been addressed in the five-year RHPR draft.

No revisions to the final report are necessary due to this Comment.

Appendix B: State’s Legal Authority to Adopt and Implement the Plan

The State’s legal authority to adopt and implement this State Implementation Plan revision can be found in Ark. Code Ann. §§ 8-4-311(a)(1) and 8-4-317.

Ark. Code Ann. § 8-4-311. Powers generally.

(a) The Arkansas Department of Environmental Quality or its successor shall have the power to:

- (1) Develop and effectuate a comprehensive program for the prevention and control of all sources of pollution of the air of this state;
- (2) Advise, consult, and cooperate with other agencies of the state, political subdivisions, industries, other states, the federal government, and with affected groups in the furtherance of the purposes of this chapter;
- (3) Encourage and conduct studies, investigations, and research relating to air pollution and its causes, prevention, control, and abatement as it may deem advisable and necessary;
- (4) Collect and disseminate information relative to air pollution and its prevention and control;
- (5) Consider complaints and make investigations;
- (6) Encourage voluntary cooperation by the people, municipalities, counties, industries, and others in preserving and restoring the purity of the air within the state;
- (7) Administer and enforce all laws and regulations relating to pollution of the air;
- (8) Represent the state in all matters pertaining to plans, procedures, or negotiations for interstate compacts in relation to air pollution control;
- (9) (A) Cooperate with and receive moneys from the federal government or any other source for the study and control of air pollution.

(B) The Department is designated as the official state air pollution control agency for such purposes;
- (10) Make, issue, modify, revoke, and enforce orders prohibiting, controlling, or abating air pollution and requiring the adoption of remedial measures to prevent, control, or abate air pollution;
- (11) Institute court proceedings to compel compliance with the provisions of this chapter and rules, regulations, and orders issued pursuant to this chapter;
- (12) Exercise all of the powers in the control of air pollution granted to the Department for the

control of water pollution under §§ 8-4-101 -- 8-4-106 and 8-4-201 -- 8-4-229; and

(13) Develop and implement state implementation plans provided that the commission shall retain all powers and duties regarding promulgation of rules and regulations under this chapter.

(b) The Arkansas Pollution Control and Ecology Commission shall have the power to:

(1) (A) Promulgate rules and regulations for implementing the substantive statutes charged to the Department for administration.

(B) In promulgation of such rules and regulations, prior to the submittal to public comment and review of any rule, regulation, or change to any rule or regulation that is more stringent than federal requirements, the commission shall duly consider the economic impact and the environmental benefit of such rule or regulation on the people of the State of Arkansas, including those entities that will be subject to the regulation.

(C) The commission shall promptly initiate rulemaking to further implement the analysis required under subdivision (b)(1)(B) of this section.

(D) The extent of the analysis required under subdivision (b)(1)(B) of this section shall be defined in the commission's rulemaking required under subdivision (b)(1)(C) of this section. It will include a written report that shall be available for public review along with the proposed rule in the public comment period.

(E) Upon completion of the public comment period, the commission shall compile a rulemaking record or response to comments demonstrating a reasoned evaluation of the relative impact and benefits of the more stringent regulation;

(2) Promulgate rules, regulations, and procedures not otherwise governed by applicable law that the commission deems necessary to secure public participation in environmental decision-making processes;

(3) Promulgate rules and regulations governing administrative procedures for challenging or contesting department actions;

(4) In the case of permitting or grants decisions, provide the right to appeal a permitting or grants decision rendered by the Director of the Arkansas Department of Environmental Quality or his or her delegatee;

(5) In the case of an administrative enforcement or emergency action, providing the right to

contest any such action initiated by the director;

(6) Instruct the director to prepare such reports or perform such studies as will advance the cause of environmental protection in the state;

(7) Make recommendations to the director regarding overall policy and administration of the Department, provided, however, that the director shall always remain within the plenary authority of the Governor;

(8) Upon a majority vote, initiate review of any director's decision;

(9) Adopt, after notice and public hearing, reasonable and nondiscriminatory rules and regulations requiring the registration of and the filing of reports by persons engaged in operations that may result in air pollution;

(10) (A) Adopt, after notice and public hearing, reasonable and nondiscriminatory rules and regulations, including requiring a permit or other regulatory authorization from the Department, before any equipment causing the issuance of air contaminants may be built, erected, altered, replaced, used, or operated, except in the case of repairs or maintenance of equipment for which a permit has been previously used, and revoke or modify any permit issued under this chapter or deny any permit when it is necessary, in the opinion of the Department, to prevent, control, or abate air pollution.

(B) A permit shall be issued for the operation or use of any equipment or any facility in existence upon the effective date of any rule or regulation requiring a permit if proper application is made for the permit.

(C) No such permit shall be modified or revoked without prior notice and hearing as provided in this section.

(D) Any person that is denied a permit by the Department or that has such permit revoked or modified shall be afforded an opportunity for a hearing in connection therewith upon written application made within thirty (30) days after service of notice of such denial, revocation, or modification.

(E) The operation of any existing equipment or facility for which a proper permit application has been made shall not be interrupted pending final action thereon.

(F) (i) An applicant or permit holder that has had a complete application for a permit or for a modification of a permit pending longer than the time specified in the state regulations

promulgated pursuant to Title V of the Clean Air Act Amendments of 1990, or any person that participated in the public participation process, and any other person that could obtain judicial review of such actions under state laws, may petition the commission for relief from Department inaction.

(ii) The commission will either deny or grant the petition within forty-five (45) days of its submittal.

(iii) For the purposes of judicial review, either a commission denial or the failure of the Department to render a final decision within thirty (30) days after the commission has granted a petition shall constitute final agency action; and

(11) (A) Establish through its rulemaking authority, either alone or in conjunction with the appropriate state or local agencies, a system for the banking and trading of air emissions designed to maintain both the state's attainment status with the national ambient air quality standards mandated by the Clean Air Act and the overall air quality of the state.

(B) The commission may consider differential valuation of emission credits as necessary to achieve primary and secondary national ambient air quality standards, and may consider establishing credits for air pollutants other than those designated as criteria air pollutants by the United States Environmental Protection Agency.

(C) Any regulation proposed pursuant to this authorization shall be reported to the House Interim Committee on Public Health, Welfare, and Labor and the Senate Interim Committee on Public Health, Welfare, and Labor or appropriate subcommittees thereof prior to its final promulgation; and

(12) In the case of a state implementation plan, provide the right to appeal a final decision rendered by the Director of the Arkansas Department of Environmental Quality or his or her delegate under § 8-4-317.

HISTORY: Acts 1949, No. 472, [Part 2], § 5, as added by Acts 1965, No. 183, § 7; A.S.A. 1947, § 82-1935; Acts 1993, No. 994, § 1; 1995, No. 895, § 4; 1997, No. 179, § 1; 1997, No. 1219, § 6; 1999, No. 1164, § 31; 2013, No. 1302, §§ 2, 3.

Ark. Code Ann. § 8-4-317. **State implementation plans generally.**

(a) In developing and implementing a state implementation plan, the Arkansas Department of Environmental Quality shall consider and take into account the factors specified in § 8-4-312 and the Clean Air Act, 42 U.S.C. §7401 *et seq.*, as applicable.

(b)(1)(A) Whenever the Department proposes to finalize a state implementation plan submittal for review and approval by the United States Environmental Protection Agency, it shall cause notice of its proposed action to be published in a newspaper of general circulation in the state.

(B) The notice required under subdivision (b)(1)(A) of this section shall afford any interested party at least thirty (30) calendar days in which to submit comments on the proposed state implementation plan submittal in its entirety.

(C)(i) In the case of any emission limit, work practice or operational standard, environmental standard, analytical method, air dispersion modeling requirement, or monitoring requirement that is incorporated as an element of the proposed state implementation plan submittal, the record of the proposed action shall include a written explanation of the rationale for the proposal, demonstrating the reasoned consideration of the factors in § 8-4-312 as applicable, the need for each measure in attaining or maintaining the National Ambient Air Quality Standards, and that any requirements or standards are based upon generally accepted scientific knowledge and engineering practices.

(ii) For any standard or requirement that is identical to an applicable federal regulation, the demonstration required under subdivision (b)(1)(C)(i) of this section may be satisfied by reference to the regulation. In all other cases, the Department shall provide its own justification with appropriate reference to the scientific and engineering literature considered or the written studies conducted by the Department.

(2)(A) At the conclusion of the public comment period and before transmittal to the Governor for submittal to the United States Environmental Protection Agency, the Department shall provide written notice of its final decision regarding the state implementation plan submittal to all persons who submitted public comments.

(B)(i) The Department's final decision shall include a response to each issue raised in any public comments received during the public comment period. The response shall manifest reasoned consideration of the issues raised by the public comments and shall be supported by appropriate legal, scientific, or practical reasons for accepting or rejecting the substance of the comment in the Department's final decision

(ii) For the purposes of this section, response to comments by the Department should serve the roles of both developing the record for possible judicial review of a state implementation plan decision and serving as a record for the public's review of the Department's technical and legal interpretations on long-range regulatory issues.

(iii) This section does not limit the Department's authority to raise all relevant issues of regulatory concern upon adjudicatory review by the Arkansas Pollution Control and Ecology Commission of a particular state implementation plan decision.

(c)(1) Only those persons that submit comments on the record during the public comment period have standing to appeal the final decision of the Department to the commission upon written application made within thirty (30) days after service of the notice under subdivision (b)(2)(A).

(2) An appeal under subdivision (c)(1) of this section shall be processed as a permit appeal under § 8-4-205. However, the decision of the Director of the Arkansas Department of Environmental Quality shall remain in effect during the appeal.

HISTORY: Acts 2013, No. 1302, § 4.

Appendix C: Evidence Public Notice Was Given

Arkansas Department of Environmental Quality

Public Notice

The Arkansas Department of Environmental Quality (ADEQ) will hold a public hearing at North Little Rock February 2, 2015, to receive comments on the proposed five-year regional haze progress report on a State Implementation Plan (SIP) revision prior to submission of the revised plan to the U.S. Environmental Protection Agency (EPA). The hearing will begin at 2:00 p.m. (Central Time) in the Commission Room at the ADEQ Headquarters Building, 5301 Northshore Drive, North Little Rock. The deadline for submitting comments on the SIP revisions is 4:30 p.m. (Central Time) February 17, 2015.

The progress report is intended to fulfill one of Arkansas's responsibilities under the Clean Air Act and Regional Haze Rule. Arkansas's original Regional Haze SIP revision was submitted to the U.S. Environmental Protection Agency (EPA) in September 2008 and addressed visibility impairment in the State's Class I Federal areas - Upper Buffalo and Caney Creek Wilderness areas. The proposed SIP is intended to address the requirements of 40 Code of Federal Register (C.F.R.) Section 51.308(g) requiring periodic reports evaluating progress towards the Reasonable Progress Goals established for mandatory Class I areas where visibility may be impacted by Arkansas sources.

This proposed SIP submittal is meant to demonstrate the actions ADEQ has taken to fulfill the requirements under 40 C.F.R. Section 51.308(g) for periodic progress reports. In accordance with 40 C.F.R. Section 51.308(h)(1), the State is submitting a negative declaration that further revision of the existing implementation plan is not needed at this time. However, ADEQ is cognizant of its obligation and the associated timeframe to address the disapproved components of the 2008 Arkansas Regional Haze SIP submittal.

ADEQ is providing the public with the opportunity to comment on this proposed SIP revision in two ways. In addition to commenting at the February 2, 2015, public hearing, interested parties may submit written or electronic mail comments prior to the comment deadline. Oral and written statements will be accepted at the hearing, but written comments are preferred in the interest of accuracy. Written comments should be mailed to Mike Bates, Air Division, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic mail comments should be sent to: bates@adeq.state.ar.us. Written or E-mail comments must be received by 4:30 p.m. (Central Time) February 17, 2015, in order to be considered.

In the event of inclement weather or other unforeseen circumstances, a decision may be made to postpone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

Copies of Arkansas's proposed SIP revision are available for public inspection during normal business hours at the Public Outreach and Assistance (POA) Division in the ADEQ headquarters building in North Little Rock and in ADEQ information depositories located in public libraries at Arkadelphia, Batesville, Blytheville, Camden, Clinton, Crossett, El Dorado, Fayetteville, Forrest City, Fort Smith, Harrison, Helena, Hope, Hot Springs, Jonesboro, Little Rock (main branch),

Magnolia, Mena, Monticello, Mountain Home, Pocahontas, Russellville, Searcy, Stuttgart, Texarkana, and West Memphis; in campus libraries at the University of Arkansas at Pine Bluff and the University of Central Arkansas at Conway; and in the Arkansas State Library, 900 W. Capitol, Suite 100, Little Rock, AR. In addition, an electronic copy of the Arkansas's proposed SIP revision is available for viewing or downloading on ADEQ's Internet web site at <http://www.adeg.state.ar.us/air/5year RH Progress Report.pdf>

Arkansas Department of
Environmental Quality
Public Notice

The Arkansas Department of Environmental Quality (ADEQ) will hold a public hearing at North Little Rock February 2, 2015, to receive comments on the proposed five-year regional haze progress report on a State Implementation Plan (SIP) revision prior to submission of the revised plan to the U.S. Environmental Protection Agency (EPA). The hearing will begin at 2:00 p.m. (Central Time) in the Commission Room at the ADEQ Headquarters Building, 5301 Northshore Drive, North Little Rock. The deadline for submitting comments on the SIP revisions is 4:30 p.m. (Central Time) February 17, 2015.

The progress report is intended to fulfill one of Arkansas's responsibilities under the Clean Air Act and Regional Haze Rule. Arkansas's original Regional Haze SIP revision was submitted to the U.S. Environmental Protection Agency (EPA) in September 2008 and addressed visibility impairment in the State's Class I Federal areas - Upper Buffalo and Caney Creek Wilderness areas. The proposed SIP is intended to address the requirements of 40 Code of Federal Register (C.F.R.) Section 51.308(g) requiring periodic reports evaluating progress towards the Reasonable Progress Goals established for mandatory Class I areas where visibility may be impacted by Arkansas sources.

This proposed SIP submittal is meant to demonstrate the actions ADEQ has taken to fulfill the requirements under 40 C.F.R. Section 51.308(g) for periodic progress reports. In accordance with 40 C.F.R. Section 51.308(h)(1), the State is submitting a negative declaration that further revision of the existing implementation plan is not needed at this time. However, ADEQ is cognizant of its obligation and the associated timeframe to address the disapproved components of the 2008 Arkansas Regional Haze SIP submittal.

ADEQ is providing the public with the opportunity to comment on this proposed SIP revision in two ways. In addition to commenting at the February 2, 2015, public hearing, interested parties may submit written or electronic mail comments prior to the comment deadline. Oral and written statements will be accepted at the hearing, but written comments are preferred in the interest of accuracy. Written comments should be mailed to Mike Bates, Air Division, Arkansas Department of Environmental Quality, 5301 Northshore Drive, North Little Rock, AR 72118. Electronic mail comments should be sent to: bates@adeq.state.ar.us. Written or E-mail comments must be received by 4:30 p.m. (Central Time) February 17, 2015, in order to be considered.

In the event of inclement weather or other unforeseen circumstances, a decision may be made to postpone the hearing. If the hearing is postponed and rescheduled, a new legal notice will be published to announce the details of the new hearing date and comment period.

Copies of Arkansas's proposed SIP revision are available for public inspection during normal business hours at the Public Outreach and Assistance (POA) Division in the ADEQ headquarters building in North Little Rock and in ADEQ information depositories located in public libraries at Arkadelphia, Batesville, Blytheville, Camden, Clinton, Crossett, El Dorado, Fayetteville, Forrest City, Fort Smith, Harrison, Helena, Hope, Hot Springs, Jonesboro, Little Rock (main branch), Magnolia, Mena, Monticello, Mountain Home, Pochontas, Russellville, Searcy, Stuttgart, Texarkana, and West Memphis; in campus libraries at the University of Arkansas at Pine Bluff and the University of Central Arkansas at Conway; and in the Arkansas State Library, 900 W. Capitol, Suite 100, Little Rock, AR. In addition, an electronic copy of the Arkansas's proposed SIP revision is available for viewing or downloading on ADEQ's internet website at [http://www.adeq.state.ar.us/air/5year R1 Progress Report.pdf](http://www.adeq.state.ar.us/air/5year%20R1%20Progress%20Report.pdf).

Appendix D: Certification That a Public Hearing Was Held

5-Year Regional Haze Progress Report Public Hearing

“Today is February 2, 2015, and we are here in the Commission Room of the Arkansas Pollution Control and Ecology Commission at the Arkansas Department of Environmental Quality for a public hearing on the SIP.

We are making SIP revisions in order to fulfill one of Arkansas’s responsibilities under the Clean Air Act and Regional Haze Rule. Arkansas’s original Regional Haze SIP revision was submitted to the U.S. Environmental Protection Agency (EPA) in September 2008 and addressed visibility impairment in the State’s Class I Federal areas - Upper Buffalo and Caney Creek Wilderness areas. The proposed SIP is intended to address the requirements of 40 Code of Federal Register (C.F.R.) Section 51.308(g) requiring periodic reports evaluating progress towards the Reasonable Progress Goals established for mandatory Class I areas where visibility may be impacted by Arkansas sources.

This proposed SIP submittal is meant to demonstrate the actions ADEQ has taken to fulfill the requirements under 40 C.F.R. Section 51.308(g) for periodic progress reports. In accordance with 40 C.F.R. Section 51.308(h)(1), the State is submitting a negative declaration that further revision of the existing implementation plan is not needed at this time. However, ADEQ is cognizant of its obligation and the associated timeframe to address the disapproved components of the 2008 Arkansas Regional Haze SIP submittal.

At this time, we will accept comments from the audience. Is there anyone who wishes to comment from the audience? [No response from those present]

Seeing no one wishing to comment, we will close the hearing and we remind everyone that the comment period will remain open until 4:30 p.m., on February 17, 2015. Thank you very much for your attendance.” —

Appendix E: Compilation of Public Comments and Response to Comments

This Appendix contains the Responsiveness Summary for public comments that were received and copies of the comment letters.

**Re: Comments Concerning the “State Implementation Plan Review
for the Five-Year Regional Haze Progress Report”**

Dear Director Benefield:

The Energy and Environmental Alliance of Arkansas (“EEAA”) and its individual members¹ are pleased to submit these comments responding to the *State Implementation Plan Review for the Five-Year Regional Haze Progress Report* (“Progress Report”), as publicly noticed by the Arkansas Department of Environmental Quality (“ADEQ” or “Department”) on January 2, 2015.

The EEAA is an ad-hoc collaboration of Arkansas’ investor-owned, co-operative, municipal, and independent electric utilities and other energy companies formed to advocate, communicate and encourage energy and environmental policies that promote sound and predictable regulation of Arkansas’ utility industry and support an economically viable and environmentally secure future for all Arkansans, including access to reliable and affordable energy resources.

Introduction and Background

Regulations implementing the regional haze visibility program of the federal Clean Air Act (“CAA”) require each state to submit reports every five years describing the progress toward the regional progress goals for each mandatory Class I federal area located in the state or outside the state if

¹ The members of EEAA are: AEP/Southwestern Electric Power Company, Arkansas Electric Cooperative Corporation, Arkansas Municipal Power Association, Conway Corporation, Empire District Electric Company, Entergy Arkansas, Inc., Jonesboro City Water & Light, North Little Rock Electric, Oklahoma Gas & Electric Company, Plum Point Services Company, LLC, and West Memphis Utility Commission.

affected by emissions from within the state.² These reports must be in the form of and satisfy the requirements for state implementation plan revisions. In addition, the regulations require that each report contain specific information, including: (i) the status of all measures included in the implementation plan for achieving reasonable progress goals; (ii) a summary of the emissions reductions achieved throughout the state; (iii) current visibility conditions and changes in visibility impairment; (iv) analysis tracking the five-year change in emissions of pollutants contributing to visibility impairment; (v) significant changes in anthropogenic sources; (vi) analysis of whether current implementation plan elements and strategies are sufficient to enable the state to meet reasonable progress goals; and (vii) a review of the state's visibility monitoring strategy.³ Finally, the report must conclude with a determination of adequacy regarding the existing regional haze implementation plan.⁴

On January 2nd, 2015, ADEQ publicly noticed the availability of the proposed Progress Report containing the information responsive to applicable regulatory requirements. The Progress Report concludes with ADEQ's proposed "negative declaration," which specifies "no additional controls are necessary during this first five-year progress report period."⁵

General Comments

I. The Progress Report and Negative Declaration Are Consistent with Federal Regulation and Guidance

Although federal regulations require that each state's five-year progress report contain specific elements, the individual states are left with the primary authority to assess and determine the "adequacy of [the] existing implementation plan."⁶ The EPA intends for the five-year progress report to "involve significantly less effort than a comprehensive SIP revision."⁷

ADEQ's Progress Report contains the elements and considerations required under federal regulation⁸, and more fully described in EPA's *General Principles for the 5-Year Regional Haze Progress Reports for the Initial Regional Haze State Implementation Plans* (Apr. 2013) ("Guidance"). The Department's

³ *Id.* § 51.308(g)(1)-(7).

⁴ *Id.* § 51.308(h).

⁵ Progress Report at 64.

⁶ 40 C.F.R. § 51.308(g) and (h).

⁷ 64 *Fed. Reg.* 35714, 35747 (July 1, 1999).

⁸ 40 C.F.R. § 51.308(g)(1)-(7)

draft enumerates each element in sequential chapters, and includes the data and analysis necessary to inform the public and EPA that Arkansas' Class I federal areas remain ahead of Uniform Rate of Progress necessary to attain the national goal of natural visibility conditions by the year 2064.⁹ For these reasons, the Progress Report is consistent with EPA's intent, as spelled out in regulation and guidance.

II. Visibility Improvement at Arkansas' Class I Federal Areas Remains Ahead of the Federally Approved Glide Path

The overarching goal of the visibility program is to restore natural visibility conditions at each Class I federal area, therefore each state's regional haze state implementation plan required an assessment of "the rate of progress needed to attain natural visibility by the year 2064" (the "Uniform Rate of Progress" or "Glide Path").¹⁰ Accordingly, Arkansas' state implementation plan provided a Uniform Rate of Progress equivalent to: (i) a 0.246 deciview (dv) per year (14.78 dv total) improvement for Caney Creek and (ii) 0.245 dv per year (14.70 dv total) improvement for Upper Buffalo.¹¹ The Uniform Rate of Progress for both areas was reviewed and approved by EPA.¹²

In order to track each state's progress toward natural visibility conditions, the regulations require that each state's five-year progress report must include an assessment of visibility conditions for the most and least impaired days, with the same expressed in terms of 5-year averages of the annual values. Specifically, the five-year progress report must provide:

- (i) current visibility conditions for the most and least impaired days;
- (ii) the difference between current visibility conditions for the most and least impaired days and the baseline visibility conditions; and
- (iii) the change in visibility impairment for the most and least impaired days from the past five years.¹³

In order to comply with these requirements, ADEQ's assessment properly utilizes the data and algorithms from the Interagency Monitoring of Protected Visual Improvements ("IMPROVE") program to chart the rate of visibility

⁹ See Progress Report at 56–57.

¹⁰ 40 C.F.R. § 51.308(d)(1)(i)(B)

¹² See 77 Fed. Reg. 14604, 14607 (Mar. 12, 2012).

¹³ 40 C.F.R. § 51.308(g)(3).

improvement.¹⁴ The data clearly demonstrates that visibility impairment is decreasing more rapidly than the federally approved Uniform Rate of Progress for each of Arkansas' Class I federal area. The continuing improvement is reflected in both the 20% worst days and 20% best days.¹⁵ The documented rate of progress supports ADEQ's negative declaration.

III. The Progress Report Documents that Arkansas' Existing Emissions Controls and Strategy are Sufficient to Make Continued, Reasonable Progress Toward Natural Visibility Conditions

Though Arkansas' reasonable progress goals, as set forth in the 2008 Arkansas Regional Haze State Implementation Plan, are not approved and final, the Department relied on the goals to conduct the analysis and assessments necessary to complete the five-year progress report. The lack of finality concerning the reasonable progress goals does nothing to impugn the validity and authority of the monitoring data and assessments articulated in the Progress Report, which clearly demonstrate that the state's existing emission controls and strategy are moving the state's Class I federal areas toward the federal goal of natural visibility conditions.

The visibility impairment at Arkansas' Class I federal areas is decreasing *more rapidly* than the federally approved Uniform Rate of Progress.¹⁶ The improvement in visibility is due in significant part to reductions in visibility related pollutants resulting from federal and state programs and increased control efficiencies from EGU sources.¹⁷ Notably, the documented improvement in visibility at Arkansas' Class I federal areas is occurring *without the implementation of best available control technology ("BART") at the state's subject-to-BART sources and without additional controls on additional sources.*¹⁸

Accordingly, the Progress Report validates the state's original determination that existing federal and state programs are adequate to make reasonable progress toward natural visibility. The full implementation of BART controls should only expedite the rapid rate of progress toward 2018 and, ultimately, 2064. In sum, the existing plan and strategy are working and

¹⁴ See Progress Report at 39–41; see also Guidance at 8–9.

¹⁵ See Progress Report at 41–43 and 56–57; Tables 4.1 and 4.2.

¹⁶ See Progress Report at 56–57.

¹⁷ See Progress Report at 35–37.

¹⁸ See Progress Report at 35 and 55.

support ADEQ's proposed negative declaration that "no additional controls are necessary during this first five-year progress period."¹⁹

Specific Comments

- Page(s) 6 and 24: The proposed Progress Report contains statements referencing the D.C. Circuit Court of Appeals grant of EPA's request to lift the stay on CSAPR and indicating that ADEQ is awaiting guidance from the agency for implementation of CSAPR. On December 3, 2014, EPA published a ministerial rule amending the dates to correctly reflect the compliance deadlines for CSAPR.²⁰ Accordingly, ADEQ should revise the applicable sections to note that CSAPR will be implemented in Arkansas beginning with the 2015 ozone season.
- Page 21: The proposed Progress Report should be revised to note that Units 1 and 2 (SN-01) and Unit 3 (SN-02) at Lake Catherine (AFIN 30-00011) were permanently retired and removed from the facility's Title V permit, issued September 26, 2014 (Permit 1717-AOP-R6).
- Page 21: The Progress Report should be updated to note that Unit 4 (SN-03) is no longer permitted to burn fuel oil, with the permitted allowance for fuel oil removed with the issuance of Permit 1717-AOP-R6 on September 26, 2014. The removal of the permitted allowance for fuel oil at Unit 4 (SN-03) eliminates any need to review and consider BART controls for the fuel oil-firing scenario, and ADEQ should highlight the significant decrease in permitted SO₂ emissions from Unit 4.
- Page(s) 30–31: Table 2-6 should be updated to include the retirement of Units 1 and 2 (SN-01) and Unit 3 (SN-02) at the Entergy - Lake Catherine facility.
- Page 37: The Progress Report states that annual SO₂ emissions are projected to increase by an additional 125 tpy in 2018 from 2011 observed emissions. This conclusory statement conflicts with language in the very next paragraph that documents an 87.5% reduction in SO₂ emissions at the SWEPCO Flint Creek Power Plant because of the operation of new control equipment. The statement also contradicts the 2018 emission projections detailed in Chapter 5, which project

¹⁹ See Progress Report at 64.

²⁰ See 79 Fed. Reg. 71663 (Dec. 3, 2014).

significant decreases in SO₂ from EGU sources. The Progress Report should be revised and/or clarified to reconcile the statement on page 37 with the projected data provided in Chapter 5.

Conclusion

ADEQ's proposed Progress Report is consistent with existing regulatory requirements and conforms to agency Guidance. The data, analysis and assessments provide ample support for the Department's "negative declaration." Perhaps most important, the Progress Report validates ADEQ's determination that current and existing emission controls are more than adequate to make reasonable progress toward the federal goal of natural visibility conditions in the year 2064.

EAEA and its members sincerely appreciate the opportunity to provide comments in support of the proposed Progress Report, and the organization remains available to provide any additional information.

Re: Comments of Nucor Steel Arkansas and of Nucor-Yamato Steel Company on
ADEQ's Five-Year Regional Haze Progress Report

Dear Mr. Benefield:

This firm represents Nucor Steel Arkansas, a division of Nucor Corporation (NSA), and Nucor Yamato Steel Company (NYS). Enclosed are NSA and NYS's comments on ADEQ's proposed Five Year Regional Haze Progress Report. Pursuant to ADEQ's public notice these comments are being submitted prior to the comment deadline at 4:30 p.m., Central Time, February 17, 2015.

Please let me know if you have any questions.

Sincerely,

DOVER DIXON HORNE

Responsiveness Summary for Public Comments on the State Implementation Plan Review for the Five-Year Regional Haze Progress Report

Two sets of comments on the State Implementation Plan Review for the Five-Year Regional Haze Progress Report (the Progress Report) were received. Both of these comments were supportive of ADEQ's determination that the Arkansas Regional Haze State Implementation Plan (SIP) and relevant suggestions were incorporated in this final Report. No adverse comments were received. Copies of the comments received (without attachments) are included herein.

The Progress Report provides an update on the status of visibility conditions in Class I areas and the implementation of the 2008 Arkansas Regional Haze SIP. One commenter "incorporates by reference" their comments submitted to EPA Region VI on December 22, 2011 regarding EPA's notice of its partial approval/disapproval of the Arkansas Regional Haze SIP. It should be noted that the comments submitted to EPA Region VI were with regards to a federal action that was promulgated as a Final Rule in the *Federal Register* on March 12, 2012. These comments would have been addressed by the EPA as part of that action. ADEQ does not consider these comments that were previously addressed by a federal agency to be relevant to the action at hand.

Appendix F: Statutory Five-Factor Analysis Letters to BART Facilities

On May 14, 2012, ADEQ sent letters to BART facilities, via certified mail through the U.S. Postal Service, with the intention to resolve disapproved portions of the 2008 Arkansas Regional Haze SIP. Facilities were asked to prepare the five-factor analysis for specific subject-to-BART units (per C.A.A. § 169(A)(g)(2)) in accordance with 40 C.F.R. Part 51, Appendix Y.

The following facilities were contacted by ADEQ (units listed below facility name):

Arkansas Electric Cooperative Corporation – Carl E. Bailey Generating Station

- Unit 1: SO₂, NO_x, and PM

Arkansas Electric Cooperative Corporation – John L. McClellan Generating Station

- Unit 1: SO₂, NO_x, and PM

American Electric Power – Flint Creek

- Unit 1: SO₂ and NO_x

Entergy – Lake Catherine

- Unit 4: NO_x for natural gas firing
- Unit 4: SO₂, NO_x, and PM for oil firing

Entergy – White Bluff

- Unit 1 and Unit 2: SO₂ and NO_x for both bituminous and sub-bituminous coal firing
- Auxiliary boiler

Domtar – Ashdown

- Power Boiler 1: SO₂ and NO_x
- Power Boiler 2: SO₂, NO_x, and PM

Georgia Pacific Paper – Crossett

- Power Boilers 6A and 9A: SO₂, NO_x, and PM

The letters are included under this Appendix for reference.

Tracy Johnson
Interim Manager, Arkansas Environmental Support
425 West Capitol Avenue
P.O. Box 551
Little Rock, AR 72203

Re: Arkansas Regional Haze Rule Revision – 5-Factor Analysis

Dear Mr. Johnson:

In accordance with CAA sections 110(a) and 169A, the Air Division of the Arkansas Department of Environmental Quality (ADEQ) is responsible for the development and implementation of a State Implementation Plan (SIP) incorporating the requirements of the federal Regional Haze Rule. ADEQ submitted a Regional Haze SIP on September 23, 2008.

On March 12, 2012, the federal Environmental Protection Agency (EPA) promulgated a Final Rule, Approval and Promulgation of Implementation Plans; Arkansas Regional Haze State Implementation Plan; Interstate Transport State Implementation Plan To Address Pollution Affecting Visibility and Regional Haze – (Federal Register, March 12, 2012), that partially disapproved the Regional Haze SIP. In response to this disapproval, ADEQ has determined that it will take measures to develop appropriate SIP revisions.

As a result, ADEQ will conduct new Best Available Retrofit Technology determinations (BART determinations) for certain facilities identified in the EPA notice. This will require that your company prepare new BART-related analyses. Specifically, ADEQ is requesting that your company submit an analysis of the five factors specified in CAA section 169(A)(g)(2) for the following affected subject to BART unit/units and pollutants:

- White Bluff's Units 1 and 2 SO₂ and NO_x for both bituminous and sub-bituminous coal firing
- White Bluff's auxiliary boiler
- Lake Catherine Unit 4 NO_x for natural gas firing
- Lake Catherine Unit 4 SO₂, NO_x, and PM for oil firing

Each "5 – Factor Analysis" is to be conducted in accordance with 40 CFR 51, App. Y and the guidance provided by ADEQ. This guidance can be obtained by accessing the BART Analysis folder located on the following ftp site:

<ftp://gis.adeg.state.ar.us/pub/AirPermits/>

The format of your submittal should closely follow the procedures described in App. Y. (Please see the attached BART Engineering Analysis Format and the letter from the U.S. EPA recommending the use of CALPUFF version 5.8, the NO OBS = 0 CALMET and CALPOST version 6.221.) This will assist ADEQ staff responsible for completing the BART determinations. I am requesting that you provide this analysis within two months of your receipt of this letter. Questions regarding the development of this analysis should be directed to Thomas Rheaume, Engineer P.E. Branch Manager at Tel. No.: (501) 682- 0762. Questions regarding air quality modeling should be directed to Mary Pettyjohn, Epidemiologist at Tel No.: (501) 682- 0070. Your immediate attention to this request is appreciated.

Sincerely,

A handwritten signature in black ink that reads "Mike Bates". The signature is written in a cursive, slightly slanted style.

Mike Bates, Chief – Air Division

Re: Arkansas Regional Haze Rule Revision – 5-Factor Analysis

Dear Mr. Gaus:

In accordance with CAA sections 110(a) and 169A, the Air Division of the Arkansas Department of Environmental Quality (ADEQ) is responsible for the development and implementation of a State Implementation Plan (SIP) incorporating the requirements of the federal Regional Haze Rule. ADEQ submitted a Regional Haze SIP on September 23, 2008.

On March 12, 2012, the federal Environmental Protection Agency (EPA) promulgated a Final Rule, Approval and Promulgation of Implementation Plans; Arkansas Regional Haze State Implementation Plan; Interstate Transport State Implementation Plan To Address Pollution Affecting Visibility and Regional Haze – (Federal Register, March 12, 2012), that partially disapproved the Regional Haze SIP. In response to this disapproval, ADEQ has determined that it will take measures to develop appropriate SIP revisions.

As a result, ADEQ will conduct new Best Available Retrofit Technology determinations (BART determinations) for certain facilities identified in the EPA notice. This will require that your company prepare new BART-related analyses. Specifically, ADEQ is requesting that your company submit an analysis of the five factors specified in CAA section 169(A)(g)(2) for the following affected subject to BART unit/units and pollutants:

- Flint Creek Unit 1 SO₂ and NO_x

Each “5 – Factor Analysis” is to be conducted in accordance with 40 CFR 51, App. Y and the guidance provided by ADEQ. This guidance can be obtained by accessing the BART Analysis folder located on the following ftp site:

<ftp://gis.adeq.state.ar.us/pub/AirPermits/>

The format of your submittal should closely follow the procedures described in App. Y. (Please see the attached BART Engineering Analysis Format and the letter from the U.S. EPA recommending the use of

CALPUFF version 5.8, the NO OBS = 0 CALMET and CALPOST version 6.221.) This will assist ADEQ staff responsible for completing the BART determinations. I am requesting that you provide this analysis within two months of your receipt of this letter. Questions regarding the development of this analysis should be directed to Thomas Rheaume, Engineer P.E. Branch Manager at Tel. No.: (501) 682- 0762. Questions regarding air quality modeling should be directed to Mary Pettyjohn, Epidemiologist at Tel No.: (501) 682- 0070. Your immediate attention to this request is appreciated.

Sincerely,

A handwritten signature in black ink that reads "Mike Bates". The signature is written in a cursive style with a large initial "M" and "B".

Mike Bates, Chief – Air Division

Re: Arkansas Regional Haze Rule Revision – 5-Factor Analysis

Dear Mr. Cain:

In accordance with CAA sections 110(a) and 169A, the Air Division of the Arkansas Department of Environmental Quality (ADEQ) is responsible for the development and implementation of a State Implementation Plan (SIP) incorporating the requirements of the federal Regional Haze Rule. ADEQ submitted a Regional Haze SIP on September 23, 2008.

On March 12, 2012, the federal Environmental Protection Agency (EPA) promulgated a Final Rule, Approval and Promulgation of Implementation Plans; Arkansas Regional Haze State Implementation Plan; Interstate Transport State Implementation Plan To Address Pollution Affecting Visibility and Regional Haze – (Federal Register, March 12, 2012), that partially disapproved the Regional Haze SIP. In response to this disapproval, ADEQ has determined that it will take measures to develop appropriate SIP revisions.

As a result, ADEQ will conduct new Best Available Retrofit Technology determinations (BART determinations) for certain facilities identified in the EPA notice. This will require that your company prepare new BART-related analyses. Specifically, ADEQ is requesting that your company submit an analysis of the five factors specified in CAA section 169(A)(g)(2) for the following affected subject to BART unit/units and pollutants:

- Bailey Plant Unit 1 SO₂, NO_x, and PM
- McClellan Plant Unit 1 SO₂, NO_x, and PM

Each "5 – Factor Analysis" is to be conducted in accordance with 40 CFR 51, App. Y and the guidance provided by ADEQ. This guidance can be obtained by accessing the BART Analysis folder located on the following ftp site:

<ftp://gis.adeg.state.ar.us/pub/AirPermits/>

The format of your submittal should closely follow the procedures described in App. Y. (Please see the attached BART Engineering Analysis Format and the letter from the U.S. EPA recommending the use of

CALPUFF version 5.8, the NO OBS = 0 CALMET and CALPOST version 6.221.) This will assist ADEQ staff responsible for completing the BART determinations. I am requesting that you provide this analysis within two months of your receipt of this letter. Questions regarding the development of this analysis should be directed to Thomas Rheaume, Engineer P.E. Branch Manager at Tel. No.: (501) 682- 0762. Questions regarding air quality modeling should be directed to Mary Pettyjohn, Epidemiologist at Tel No.: (501) 682- 0070. Your immediate attention to this request is appreciated.

Sincerely,

A handwritten signature in black ink that reads "Mike Bates". The signature is written in a cursive style with a horizontal line extending from the end of the name.

Re: Arkansas Regional Haze Rule Revision – 5-Factor Analysis

Dear Ms. Crouch:

In accordance with CAA sections 110(a) and 169A, the Air Division of the Arkansas Department of Environmental Quality (ADEQ) is responsible for the development and implementation of a State Implementation Plan (SIP) incorporating the requirements of the federal Regional Haze Rule. ADEQ submitted a Regional Haze SIP on September 23, 2008.

On March 12, 2012, the federal Environmental Protection Agency (EPA) promulgated a Final Rule, Approval and Promulgation of Implementation Plans; Arkansas Regional Haze State Implementation Plan; Interstate Transport State Implementation Plan To Address Pollution Affecting Visibility and Regional Haze – (Federal Register, March 12, 2012), that partially disapproved the Regional Haze SIP. In response to this disapproval, ADEQ has determined that it will take measures to develop appropriate SIP revisions.

As a result, ADEQ will conduct new Best Available Retrofit Technology determinations (BART determinations) for certain facilities identified in the EPA notice. This will require that your company prepare new BART-related analyses. Specifically, ADEQ is requesting that your company submit an analysis of the five factors specified in CAA section 169(A)(g)(2) for the following affected subject to BART unit/units and pollutants:

- Domtar Ashdown's Power Boiler # 1 SO₂ and NO_x
- Domtar Ashdown's Power Boiler #2 SO₂, NO_x, and PM

Each "5 – Factor Analysis" is to be conducted in accordance with 40 CFR 51, App. Y and the guidance provided by ADEQ. This guidance can be obtained by accessing the BART Analysis folder located on the following ftp site:

<ftp://gis.adeq.state.ar.us/pub/AirPermits/>

The format of your submittal should closely follow the procedures described in App. Y. (Please see the attached BART Engineering Analysis Format and the letter from the U.S. EPA recommending the use of CALPUFF version 5.8, the NO OBS = 0 CALMET and CALPOST version 6.221.) This will assist ADEQ staff responsible for completing the BART determinations. I am requesting that you provide this analysis within two months of your receipt of this letter. Questions regarding the development of this analysis should be directed to Thomas Rheaume, Engineer P.E. Branch Manager at Tel. No.: (501) 682- 0762. Questions regarding air quality modeling should be directed to Mary Pettyjohn, Epidemiologist at Tel No.: (501) 682- 0070. Your immediate attention to this request is appreciated.

Sincerely,

A handwritten signature in black ink that reads "Mike Bates". The signature is written in a cursive style with a large, stylized "M" and "B".

Arkansas Regional Haze FIP update

Facility Name	Emission Units Subject-to-BART	Unit Description	EPA Final Action on 2008 RH SIP (3/12/12)	Baseline Visibility Impacts from Source	BART Limits Recommended by State and Facilities (We recommend going with these limits in our proposed FIP)
<p style="text-align: center;">Arkansas Electric Cooperative Corporation (AECC) Carl E. Bailey Plant</p>	<p>Boiler SN-01 Installation date- 1966</p>	<p>122 MW-- burns primarily natural gas and also fuel oil</p>	<p>Disapproved SO₂, NO_x, and PM BART</p>	<p>Caney Creek= 0.330 dv Upper Buffalo= 0.348 dv</p>	<p>SO₂ BART= 0.5% Sulfur Fuel Total Annual Cost= \$68,587 SO₂ tons removed= 26.80 tpy Average Cost effectiveness: \$2,559/ton removed Visibility Improvement at Caney Creek: 0.188 dv Visibility Improvement at Upper Buffalo: 0.221 dv Incremental Cost Effectiveness (compared to 1% Sulfur fuel): \$4,693/ ton removed Incremental Visibility improvement over 1% Sulfur fuel at Caney Creek: 0.051 dv Incremental Visibility improvement over 1% Sulfur fuel at Upper Buffalo: 0.067 dv</p> <p><u>Other SO₂ Controls Evaluated (which we are not recommending):</u></p> <p><u>Switch to 1% sulfur fuel oil:</u> Total Annual Cost= \$19,596 SO₂ tons removed= 16.36 tpy Average Cost effectiveness: \$1,198/ ton removed Visibility Improvement at Caney Creek: 0.137 dv Visibility Improvement at Upper Buffalo: 0.154 dv Incremental Cost Effectiveness: NA, least stringent option evaluated Incremental Visibility improvement at Caney Creek: NA, least stringent option evaluated Incremental Visibility improvement at Upper Buffalo: NA, least stringent option evaluated</p> <p><u>Switch to Diesel (0.05% sulfur content):</u> Total Annual Cost= \$194,003 SO₂ tons removed= 36.05 tpy Average Cost effectiveness: \$5,382/ ton removed Visibility Improvement at Caney Creek: 0.246 dv Visibility Improvement at Upper Buffalo: 0.279 dv Incremental Cost Effectiveness (compared to 0.5% Sulfur fuel): \$13,558/ ton removed Incremental Visibility improvement over 0.5% Sulfur fuel at Caney Creek: 0.058 dv Incremental Visibility improvement over 0.5% Sulfur fuel at Upper Buffalo: 0.058 dv</p> <p><u>Switch to Natural Gas:</u> Total Annual Cost= (\$384,550) SO₂ tons removed= 37.02 Average Cost effectiveness: -\$10,387/ ton removed (Note: negative value means there is a cost savings when switching from baseline fuel oil to natural gas) Visibility Improvement at Caney Creek: 0.247 dv Visibility Improvement at Upper Buffalo: 0.276 dv Incremental Cost Effectiveness (compared to diesel): N/A, natural gas is more cost effective Incremental Visibility improvement over diesel at Caney Creek: 0.001 dv Incremental Visibility improvement over diesel at Upper Buffalo: -0.003 dv</p>

- Note: The total annual cost was calculated as the difference between the total annual cost of the baseline fuel oil and the total annual cost of each fuel switching option. Therefore, the total annual cost of switching to natural gas is a negative value due to the current lower cost of natural gas compared to the baseline fuel oil burned at the facility. The baseline fuel oil has a sulfur content of 1.81%.
- Although natural gas is the most cost-effective option based on the current market prices, we recommend that BART is switching to fuels with a sulfur content of no more than 0.5%. This will continue to give the facility the flexibility to burn either fuel oil or natural gas, especially considering that because of cost variability, natural gas curtailments, and other factors, the ability to burn fuel oil is important to the facility.

NOx BART= Existing emission limit/No Additional Controls

Other NOx Controls Evaluated (which we are not recommending):

LNB/OFA/FGR (0.15 lb/MMBtu):

Total Annual Cost= \$700,477
NOx tons removed= 18.98 tpy
Average Cost effectiveness: \$36,905/ ton removed
Visibility Improvement at Caney Creek: 0.005 dv
Visibility Improvement at Upper Buffalo: 0.015 dv
Incremental Cost Effectiveness: NA, least stringent option evaluated
Incremental Visibility improvement at Caney Creek: NA, least stringent option evaluated
Incremental Visibility improvement at Upper Buffalo: NA, least stringent option evaluated

LNB/OFA/FGR + SNCR (0.12 lb/MMBtu):

Total Annual Cost= \$1,223,157
NOx tons removed= 25.02 tpy
Average Cost effectiveness: \$48,884/ ton removed
Visibility Improvement at Caney Creek: 0.005 dv
Visibility Improvement at Upper Buffalo: 0.018 dv
Incremental Cost Effectiveness (compared to LNB/OFA/FGR): \$86,536/ ton removed
Incremental Visibility improvement over LNB/OFA/FGR at Caney Creek: 0 dv
Incremental Visibility improvement over LNB/OFA/FGR at Upper Buffalo: 0.003 dv

SCR (0.05 lb/MMBtu):

Total Annual Cost= \$1,555,718
NOx tons removed= 40.16 tpy
Average Cost effectiveness: \$38,738/ ton removed
Visibility Improvement at Caney Creek: 0.007 dv
Visibility Improvement at Upper Buffalo: 0.022 dv
Incremental Cost Effectiveness (compared to LNB/OFA/FGR + SNCR): \$21,966/ ton removed
Incremental Visibility improvement over LNB/OFA/FGR + SNCR at Caney Creek: 0.002 dv
Incremental Visibility improvement over LNB/OFA/FGR + SNCR at Upper Buffalo: 0.004 dv

Rationale for Existing emission limit/No additional controls:

- None of the NOx control options evaluated are cost effective.
- All control options evaluated would result in minimal visibility benefit.

Plant**

Other PM Controls Evaluated (which we are not recommending), continued:

Wet Scrubber (55% control):

Total Annual Cost= \$50,150,862

PM tons removed= 14.09 tpy

Average Cost effectiveness: \$3,558,286/ ton removed

Visibility Improvement at Caney Creek: 0.002 dv

Visibility Improvement at Upper Buffalo: 0.002 dv

Incremental Cost Effectiveness: NA, least stringent control technology

Incremental Visibility improvement at Caney Creek: NA, least stringent control technology

Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology

Cyclone (85% control):

Total Annual Cost= \$1,188,630

PM tons removed= 21.78 tpy

Average Cost effectiveness: \$54,570/ ton removed

Visibility Improvement at Caney Creek: 0.002 dv

Visibility Improvement at Upper Buffalo: 0.002 dv

Incremental Cost Effectiveness (compared to Wet Scrubber): NA, cyclone is more cost effective

Incremental Visibility improvement over Wet Scrubber at Caney Creek: 0 dv

Incremental Visibility improvement over Wet Scrubber at Upper Buffalo: 0 dv

Wet ESP (90% control):

Total Annual Cost= \$22,638,340

PM tons removed= 23.06 tpy

Average Cost effectiveness: \$981,583/ ton removed

Visibility Improvement at Caney Creek: 0.003 dv

Visibility Improvement at Upper Buffalo: 0.004 dv

Incremental Cost Effectiveness (compared to Cyclone): \$16,757,586/ ton removed

Incremental Visibility improvement over Cyclone at Caney Creek: 0.001 dv

Incremental Visibility improvement over Cyclone at Upper Buffalo: 0.002 dv

- Our recommendation is consistent with that of SO₂ BART for the source.
- Lower sulfur content of the fuel combusted also results in lower PM emissions.
- All other more stringent options are not cost-effective.

Average Cost effectiveness: \$1,762/ton removed

Visibility Improvement at Caney Creek: 0.114 dv

Visibility Improvement at Upper Buffalo: 0.026 dv

Incremental Cost Effectiveness: NA, least stringent control technology

Incremental Visibility improvement at Caney Creek: NA, least stringent control technology

Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology

Other NO_x Controls Evaluated (which we are not recommending):

LNB/OFA + SNCR (0.2 lb/MMBtu):

Total Annual Cost= \$4,177,782

NO_x tons removed= 1,348.45 tpy

Average Cost effectiveness: \$3,099/ton removed

Visibility Improvement at Caney Creek: 0.114 dv

Visibility Improvement at Upper Buffalo: 0.033 dv

Incremental Cost Effectiveness (compared to LNB/OFA): \$5,209/ton removed

Incremental Visibility improvement over LNB/OFA at Caney Creek: 0.000 dv

Incremental Visibility improvement over LNB/OFA at Upper Buffalo: 0.007 dv

SCR (0.07 lb/MMBtu):

Total Annual Cost= \$13,769,599

NO_x tons removed= 3,869.22 tpy

Average Cost effectiveness: \$3,559/ton removed

Visibility Improvement at Caney Creek: 0.245 dv

Visibility Improvement at Upper Buffalo: 0.07 dv

Incremental Cost Effectiveness (compared to LNB/OFA + SNCR): \$3,805/ton removed

Incremental Visibility improvement over LNB/OFA + SNCR at Caney Creek: 0.131 dv

Incremental Visibility improvement over LNB/OFA + SNCR at Upper Buffalo: 0.037 dv

Rationale for not selecting SNCR or SCR for NO_x BART

- Facility offered to install LNB/OFA to meet BART requirement, even though the visibility benefit is on the low end considering the cost in terms of \$/ton. Some could argue against controlling for NO_x at all due to the relatively low visibility benefit.
- LNB/OFA + SNCR has no incremental visibility benefit over LNB/OFA alone at Caney Creek and negligible incremental visibility improvement at Upper Buffalo, so this makes for a strong case against SNCR.
- SCR has a cost (\$/ton) somewhat on the high end, although it is expected to result in around twice as much visibility improvement as LNB/OFA.

<p>Entergy White Bluff Plant</p>	<p>Unit 1 Installation date- 1974</p>	<p>850 MW-- burns sub-bituminous or bituminous coal as primary fuel; No. 2 fuel oil is startup fuel</p>	<p>Approved PM BART Disapproved SO2 and NOx BART</p>	<p>Caney Creek= 1.628 dv Upper Buffalo= 1.140 dv</p>	<p>SO2 BART= 0.06 lb/MMBtu (using dry scrubbing) Total Annual Cost= \$31,981,230 SO2 tons removed= 14,363 tpy Average Cost effectiveness: \$2,227/ton removed Visibility Improvement at Caney Creek: 0.813 dv Visibility Improvement at Upper Buffalo: 0.762 dv Incremental Cost Effectiveness: NA, least stringent control technology Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>Other SO2 Controls Evaluated (which we are not recommending):</u></p> <p><u>Wet Scrubbers (0.04 lb/MMBtu):</u> Total Annual Cost= \$65,942,351 SO2 tons removed= 18,445 tpy Average Cost effectiveness: \$3,575/ ton removed Visibility Improvement at Caney Creek: 0.834 dv Visibility Improvement at Upper Buffalo: 0.79 dv Incremental Cost Effectiveness (compared to NID): \$8,320/ ton removed Incremental Visibility improvement over NID at Caney Creek: 0.021 dv Incremental Visibility improvement over NID at Upper Buffalo: 0.028 dv</p>
---	---	---	---	--	--

Rationale for not selecting Wet Scrubbers for SO2 BART

- Dry scrubbers are much more cost effective than wet scrubbers; while wet scrubbers offer very little incremental visibility improvement.

**Entergy
White Bluff
Plant**

Unit 1

NO_x BART= 0.15 lb/MMBtu (using LNB/SOFA)

Total Annual Cost= \$1,085,904

NO_x tons removed= 3,104 tpy

Average Cost effectiveness: \$350/ton removed

Visibility Improvement at Caney Creek: 0.166 dv

Visibility Improvement at Upper Buffalo: 0.101 dv

Incremental Cost Effectiveness: NA, least stringent control technology

Incremental Visibility improvement at Caney Creek: NA, least stringent control technology

Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology

Other NO_x Controls Evaluated (which we are not recommending):

LNB/SOFA + SNCR (0.13 lb/MMBtu):

Total Annual Cost= \$6,430,580

NO_x tons removed= 3,657 tpy

Average Cost effectiveness: \$1,758/ton removed

Visibility Improvement at Caney Creek: 0.2 dv

Visibility Improvement at Upper Buffalo: 0.111 dv

Incremental Cost Effectiveness (compared to LNB/SOFA): \$9,665/ton removed

Incremental Visibility improvement over LNB/SOFA at Caney Creek: 0.034 dv

Incremental Visibility improvement over LNB/SOFA at Upper Buffalo: 0.01 dv

LNB/SOFA + SCR (0.055 lb/MMBtu):

Total Annual Cost= \$20,349,142

NO_x tons removed= 5,729 tpy

Average Cost effectiveness: \$3,552/ton removed

Visibility Improvement at Caney Creek: 0.269 dv

Visibility Improvement at Upper Buffalo: 0.149 dv

Incremental Cost Effectiveness (compared to LNB/SOFA + SNCR): \$6,717/ton removed

Incremental Visibility improvement over LNB/SOFA + SNCR at Caney Creek: 0.069 dv

Incremental Visibility improvement over LNB/SOFA + SNCR at Upper Buffalo: 0.038 dv

Rationale for not selecting SNCR or SCR for NO_x BART

- Although LNB/SOFA + SNCR is cost-effective, the incremental cost effectiveness compared to LNB/SOFA alone is high while the incremental visibility benefit is very small (0.034 dv and 0.01 dv).
- The cost (\$/ton) of LNB/SOFA + SCR is somewhat on the high end, and the incremental visibility benefit compared to LNB/SOFA + SNCR is relatively small (0.069 dv and 0.038 dv).

<p>Entergy White Bluff Plant</p>	<p>Unit 2 Installation date- 1974</p>	<p>850 MW-- burns sub-bituminous or bituminous coal as primary fuel; No. 2 fuel oil is startup fuel</p>	<p>Approved PM BART Disapproved SO2 and NOx BART</p>	<p>Caney Creek= 1.695 dv Upper Buffalo= 1.185 dv</p>	<p>SO2 BART= 0.06 lb/Mmbtu (using dry scrubbers) Total Annual Cost= \$31,981,230 SO2 tons removed= 15,221 tpy Average Cost effectiveness: \$2,101/ton removed Visibility Improvement at Caney Creek: 0.754 dv Visibility Improvement at Upper Buffalo: 0.767 dv Incremental Cost Effectiveness: NA, least stringent control technology Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>Other SO2 Controls Evaluated (which we are not recommending):</u></p> <p><u>Wet Scrubbers (0.04 lb/MMBtu):</u> Total Annual Cost= \$65,942,351 SO2 tons removed= 16,084 tpy Average Cost effectiveness: \$4,100/ ton removed Visibility Improvement at Caney Creek: 0.775 dv Visibility Improvement at Upper Buffalo: 0.78 dv Incremental Cost Effectiveness (compared to dry scrubbers): \$39,352/ ton removed Incremental Visibility improvement over dry scrubbers at Caney Creek: 0.021 dv Incremental Visibility improvement over dry scrubbers at Upper Buffalo: 0.013 dv</p>
---	---	---	---	--	---

Rationale for not selecting Wet Scrubbers for SO2 BART

- Dry scrubbers are much more cost effective than wet scrubbers; while wet scrubbers offer very little incremental visibility improvement.

<p style="text-align: center;">Entergy White Bluff Plant</p>	<p style="text-align: center;">Unit 2</p>				<p><u>NOx BART= 0.15 lb/MMBtu (using LNB/SOFA)</u> Total Annual Cost= \$1,403,376 NOx tons removed= 4,125 tpy Average Cost effectiveness: \$340/ton removed Visibility Improvement at Caney Creek: 0.225 dv Visibility Improvement at Upper Buffalo: 0.139 dv Incremental Cost Effectiveness: NA, least stringent control technology Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>Other NOx Controls Evaluated (which we are not recommending):</u></p> <p><u>LNB/SOFA + SNCR (0.13 lb/MMBtu):</u> Total Annual Cost= \$ 6,759,102 NOx tons removed= 4,666 tpy Average Cost effectiveness: \$1,449 /ton removed Visibility Improvement at Caney Creek: 0.258 dv Visibility Improvement at Upper Buffalo: 0.15 dv Incremental Cost Effectiveness (compared to LNB/SOFA): \$9,900 /ton removed Incremental Visibility improvement over LNB/SOFA at Caney Creek: 0.033 dv Incremental Visibility improvement over LNB/SOFA at Upper Buffalo: 0.011 dv</p> <p><u>LNB/SOFA + SCR (0.055 lb/MMBtu):</u> Total Annual Cost= \$ 18,407,977 NOx tons removed= 6,697 tpy Average Cost effectiveness: \$2,749/ton removed Visibility Improvement at Caney Creek: 0.327 dv Visibility Improvement at Upper Buffalo: 0.188 dv Incremental Cost Effectiveness (compared to LNB/SOFA + SNCR): \$5,736 /ton removed Incremental Visibility improvement over LNB/SOFA + SNCR at Caney Creek: 0.069 dv Incremental Visibility improvement over LNB/SOFA + SNCR at Upper Buffalo: 0.038 dv</p>
---	---	--	--	--	--

Rationale for not selecting SNCR or SCR for NOx BART.

- Although LNB/SOFA + SNCR is cost-effective, the incremental cost effectiveness compared to LNB/SOFA alone is high while the incremental visibility benefit is very small (0.033 dv and 0.011 dv).
- The cost (\$/ton) of LNB/SOFA + SCR is slightly high, and the incremental visibility benefit compared to LNB/SOFA + SNCR is relatively small (0.069 dv and 0.038 dv).

<p>Entergy Lake Catherine Plant</p>	<p>Unit 4 Installation date-1970</p>	<p>552 MW-- burns primarily natural gas; No. 6 fuel oil is secondary fuel</p>	<p>Natural Gas Firing</p>	<p>Approved SO₂, PM BART Disapproved NO_x BART</p>	<p>Caney Creek= 1.371 dv Upper Buffalo= 0.532 dv</p>	<p>Natural Gas Firing Scenario:</p> <p>NO_x BART= 0.22 lb/MMBtu (using Burners Out of Service) Total Annual Cost= \$92,964 NO_x tons removed= 673 tpy Average Cost effectiveness: \$138/ton removed Visibility Improvement at Caney Creek: 0.596 dv Visibility Improvement at Upper Buffalo: 0.248 dv Incremental Cost Effectiveness: NA, least stringent control technology Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>Other NO_x Controls Evaluated (which we are not recommending):</u></p> <p><u>LNB/SOFA (0.19 lb/MMBtu):</u> Total Annual Cost= \$1,075,905 NO_x tons removed= 742 tpy Cost effectiveness: \$1,450/ton removed Visibility Improvement at Caney Creek: 0.688 dv Visibility Improvement at Upper Buffalo: 0.282 dv Incremental Cost Effectiveness (compared to BOOS): \$14,246/ton removed Incremental Visibility improvement over BOOS at CC: 0.092 dv Incremental Visibility improvement over BOOS at UB: 0.036 dv</p> <p><u>LNB/SOFA + SNCR (0.14 lb/MMBtu):</u> Total Annual Cost= \$3,047,525 NO_x tons removed= 865 tpy Cost effectiveness: \$3,523/ton removed Visibility Improvement at Caney Creek: 0.842 dv Visibility Improvement at Upper Buffalo: 0.339 dv Incremental Cost Effectiveness (compared to LNB/SOFA): \$16,029/ton removed Incremental Visibility improvement over LNB/SOFA at Caney Creek: 0.154 dv Incremental Visibility improvement over LNB/SOFA at Upper Buffalo: 0.057 dv</p> <p><u>LNB/SOFA + SCR (0.03 lb/MMBtu):</u> Total Annual Cost= \$6,506,935 NO_x tons removed= 1,159 tpy Cost effectiveness: \$5,614/ton removed Visibility Improvement at Caney Creek: 1.208 dv Visibility Improvement at Upper Buffalo: 0.475 dv Incremental Cost Effectiveness (compared to LNB/SOFA + SNCR): \$11,767/ton removed Incremental Visibility improvement over LNB/SOFA + SNCR at Caney Creek: 0.52 dv Incremental Visibility improvement over LNB/SOFA + SNCR at Upper Buffalo: 0.193 dv</p>
--	--	---	---------------------------	--	--	---

Rationale for not selecting LNB/SOFA or other more stringent controls for NO_x BART.

- The incremental cost effectiveness of LNB/SOFA compared to Burners out of Service is \$14,246/ ton removed. **The incremental cost effectiveness was calculated as follows: (Total Annual Cost of LNB/SOFA - Total Annual Cost of BOOS) / (Annual NO_x emissions reductions due to LNB/SOFA - Annual NO_x emissions reductions due to BOOS) = (\$1,075,905 - \$92,964) / (742 tpy – 673 tpy) = \$14,246/ ton removed.**
- Based on feedback we have received from OGC in the past, where the incremental cost effectiveness is greater than \$10,000/ton removed, we can rule out that technology based on cost.
- The incremental cost effectiveness of SNCR and SCR is also greater than \$10,000/ton removed.
- Although LNB/SOFA is cost-effective, the incremental visibility benefit over Burners out of Service is under 0.1 dv, yet the cost on a \$/ton basis is much higher than Burners out of Service (\$1,450/ton removed vs. \$138/ton removed).
- Lake Catherine Unit 4 is an oil/gas fired peaking unit, with NO_x baseline emissions of 1,236 tpy. By comparison, AEP/SWEPCO Flint Creek Unit 1 is a coal fired base load unit with NO_x baseline emissions of 5,120 tpy.

<p>Entergy Lake Catherine Plant</p>	<p>Unit 4</p>		<p>Fuel Oil Firing</p>	<p>Disapproved SO₂, NO_x, and PM BART</p>	<p>Caney Creek= 1.371 dv Upper Buffalo= 0.532 dv</p>	<p>Fuel Oil Firing Scenario:</p> <p>Facility has not burned fuel oil in over 10 years and does not anticipate burning fuel oil in the near future, and would therefore like to defer getting a BART determination until they start burning fuel oil. Facility will accept a permit condition that would not allow fuel burning until BART limit is in place.</p>
<p>Domtar-Ashdown Mill</p>	<p>Power Boiler #1 (SN-03) Installation date- 1968</p>	<p>580 MMBtu/hr-- combusts primarily bark (75%), also fuel oil and natural gas</p>	<p>Approved PM BART Disapproved SO₂ and NO_x BART</p>	<p>Caney Creek= 0.335 dv Upper Buffalo= 0.038 dv</p>	<p>SO₂ BART= 21.0 lb/hr (Baseline Emission Rate/No Additional Controls)</p> <p>Facility took a streamlined approach to the BART analysis due to the low baseline emissions and that the boiler burns primarily bark, which has low sulfur content.</p>	

<p style="text-align: center;">Domtar- Ashdown Mill</p>	<p style="text-align: center;">Power Boiler #1</p>				<p><u>NOx BART= 207.4 lb/hr</u> (Baseline Emission Rate//No Additional Controls)</p> <p><u>Other NOx Controls Evaluated (which we are not recommending):</u></p> <p><u>SNCR (20% control):</u> Total Annual Cost= \$ 1,118,178 NOx tons removed= 88 tpy Cost effectiveness: \$12,700/ ton removed Visibility Improvement at Caney Creek: 0.061 dv Visibility Improvement at Upper Buffalo: 0.007 dv Incremental Cost Effectiveness: NA, least stringent control technology evaluated Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>SNCR (32.5% control):</u> Total Annual Cost= \$1,144,103 NOx tons removed= 143 tpy Cost effectiveness: \$7,996/ ton removed Visibility Improvement at Caney Creek: 0.098 dv Visibility Improvement at Upper Buffalo: 0.011 dv Incremental Cost Effectiveness (compared to 20% control): \$471/ ton removed Incremental Visibility improvement over 20% control at Caney Creek: 0.037 dv Incremental Visibility improvement over 20% control at Upper Buffalo: 0.004 dv</p> <p><u>SNCR (45% control):</u> Total Annual Cost= \$1,513,602 NOx tons removed= 379 tpy Cost effectiveness: \$7,640/ ton removed Visibility Improvement at Caney Creek: 0.136 dv Visibility Improvement at Upper Buffalo: 0.015 dv Incremental Cost Effectiveness (compared to 20% control): \$1,566/ ton removed Incremental Visibility improvement over 20% control at Caney Creek: 0.038 dv Incremental Visibility improvement over 20% control at Upper Buffalo: 0.004 dv</p>
--	--	--	--	--	--

Rationale for not selecting SNCR for NOx BART:

- Facility evaluated SNCR at various levels of control, although they believe 20% removal efficiency is the most reasonable estimate of the level of NO_x control SNCR can achieve at Power Boiler No. 1 on a long-term basis due to the boiler's high load swing.
- When operated at 20% removal efficiency, SNCR is projected to result in visibility improvement of 0.061 and 0.007 dv and is estimated to cost \$12,700 per ton of NO_x removed. We do not believe this high cost justifies the modest visibility improvement projected from the installation and operation of SNCR at 20% removal efficiency.
- In the BART evaluation submitted as part of the 2008 Arkansas RH SIP, LNB, ultra-Low NO_x Burners, OFA, Flue gas recirculation, and SCR were considered and determined to be technically infeasible for this boiler.

<p>Domtar-Ashdown Mill</p>	<p>Power Boiler #2 (SN-05) Installation date- 1975</p>	<p>820 MMBtu/hr-- combusts primarily bituminous coal (80%), also bark/wood chips, natural gas</p>	<p>Disapproved SO₂, NO_x, and PM BART</p>	<p>Caney Creek= 0.844 dv Upper Buffalo= 0.146 dv</p>	<p>SO₂ BART= Facility is recommending an emission limit of 0.31 lb/MMBtu (Based on the use of additional scrubbing reagent in the existing scrubbers)</p> <p>**We are recommending an emission limit in the range of 0.11 lb/MMBtu, which is representative of operating the existing scrubbers at 90% control efficiency, we will invite comment in our proposal on the appropriateness of this emission limit**</p> <p>Total Annual Cost= \$1,960,434 SO₂ tons removed= 1,401 tpy Average Cost effectiveness: \$1,411/ton removed Estimated Visibility Improvement at Caney Creek: 0.139 dv Estimated Visibility Improvement at Upper Buffalo: 0.05 dv Incremental Cost Effectiveness: NA, least stringent control technology evaluated Incremental Visibility improvement at Caney Creek: NA, least stringent control technology Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology</p> <p><u>Other SO₂ Controls Evaluated (which we are not recommending):</u></p> <p><u>Add-on Spray Scrubbers:</u> Total Annual Cost= \$9,833,378 SO₂ tons removed= 1,870 tpy Average Cost effectiveness: \$5,258/ ton removed Visibility Improvement at Caney Creek: 0.146 dv Visibility Improvement at Upper Buffalo: 0.053 dv Incremental Cost Effectiveness (compared to using additional scrubbing reagent): \$16,787/ ton removed Incremental Visibility improvement over additional scrubbing reagent at Caney Creek: 0.007 dv Incremental Visibility improvement over additional scrubbing reagent at Upper Buffalo: 0.003 dv</p>
-----------------------------------	--	---	--	--	---

Rationale for not selecting Add-On Spray Scrubbers for SO₂ BART:

- The cost of add-on spray scrubbers (which would have been added on top of the existing wet venturi scrubbers) is estimated to be much higher than using the existing scrubbers with additional scrubbing reagent. Add-on spray scrubbers would also have negligible incremental visibility benefit.

**Domtar-
Ashdown
Mill**

Power Boiler #2

NO_x BART= 345 lb/hr (using LNB, 30% control)

Total Annual Cost: \$899,605

NO_x tons removed= 461 tpy

Average Cost effectiveness: \$1,951/ton removed

Visibility Improvement at Caney Creek: 0.181 dv

Visibility Improvement at Upper Buffalo: 0.014 dv

Incremental Cost Effectiveness (compared to SNCR 27.5% control): \$1,437/ ton removed

Incremental Visibility improvement at Caney Creek: 0.015 dv

Incremental Visibility improvement at Upper Buffalo: 0.002 dv

Other NO_x Controls Evaluated (which we are not recommending):

SNCR (27.5% control):

Total Annual Cost= \$843,575

NO_x tons removed= 422 tpy

Cost effectiveness: \$1,998/ ton removed

Visibility Improvement at Caney Creek: 0.166 dv

Visibility Improvement at Upper Buffalo: 0.012 dv

Incremental Cost Effectiveness: NA, least stringent control technology

Incremental Visibility improvement at Caney Creek: NA, least stringent control technology

Incremental Visibility improvement at Upper Buffalo: NA, least stringent control technology

SNCR (35% control):

Total Annual Cost= \$1,026,214

NO_x tons removed= 537 tpy

Cost effectiveness: \$1,909/ ton removed

Visibility Improvement at Caney Creek: 0.212 dv

Visibility Improvement at Upper Buffalo: 0.017 dv

Incremental Cost Effectiveness (compared to LNB): \$/ ton removed

Incremental Visibility improvement over LNB at Caney Creek: 0.031 dv

Incremental Visibility improvement over LNB at Upper Buffalo: 0.003 dv

Rationale for not selecting SNCR for NO_x BART:

- SNCR was evaluated at 27.5% and 35% control efficiency, but based on the information provided by the facility we believe that due to the wide variability in steam demand and wide range in furnace temperature observed in Power Boiler No. 2, the NO_x control efficiency of SNCR at the boiler would not reach 35% control on a long-term basis.
- There is uncertainty as to the level of control efficiency that SNCR is able to achieve on a long-term basis for Power Boiler No. 2.
- LNB are cost effective and are expected to result in considerable visibility improvement.

Domtar-Ashdown Mill	Power Boiler #2				<p>PM BART= 0.44 lb/MMBtu (No Additional Controls)</p> <p>0.44 lb/MMBtu is the PM Boiler MACT standard the boiler is subject to. The BART Guidelines allow for a streamlined approach for determining BART for sources subject to the PM Boiler MACT standard. As long as no new cost-effective technologies have been developed subsequent to the MACT standards, the MACT standard may be relied on to satisfy the BART requirement. We recommend taking the streamlined approach for determining BART in this case.</p>
----------------------------	-----------------	--	--	--	---

Reasonable Progress Analysis

Issue: Do we propose SO₂ and NO_x controls on the Entergy Independence Power Plant (a non-BART source) under the Reasonable Progress Requirements?

Option 1: Propose No Additional Controls under Reasonable Progress

- CENRAP modeling shows all Arkansas areas are on or beneath the glide path.
- This approach would not be consistent with our TX/OK Regional Haze FIP proposal.

Option 2: Propose Only SO₂ Controls under Reasonable Progress

- Independence and White Bluff (BART source) are sister facilities, and they have similar baseline visibility impacts at Arkansas Class I areas.
- Independence is currently the second largest point source of SO₂ emissions in Arkansas (2011 NEI), so it is an obvious source to evaluate for controls under RP.
- Based on CALPUFF modeling, the visibility improvement of SO₂ controls at affected Class I areas is projected to be considerable.
- The approach of proposing SO₂ controls and no NO_x controls under RP is consistent with our TX/OK Regional Haze FIP proposal.
- Under Reasonable Progress, the focus is on improving the 20% worst days, and CENRAP modeling shows that SO₂ is the driver while NO_x is not a driver of regional haze on the 20% worst days at Arkansas Class I areas.

Option 3: Propose Both SO₂ and NO_x Controls Under Reasonable Progress

- Both SO₂ and NO_x controls are estimated to be cost-effective and are projected to result in considerable visibility benefit at the affected Class I areas based on CALPUFF modeling that looks at the 8th high day of the modeled period.
- This approach would not be somewhat inconsistent with our TX/OK Regional Haze FIP proposal.

Recommendation: Our recommendation is Option 3 above. Propose an SO₂ emission limit of 0.06 lb/MMBtu and a NO_x emission limit of 0.15 lb/MMBtu under Reasonable Progress for Units 1 and 2 of the Independence Power Plant, based on the installation of semi-dry scrubbers and LNB/SOFA. We will invite public comment on whether NO_x controls are appropriate. Expect significant comment on this issue.

SUBJECT:
Request for Limited Extension of Public Comment Period
– Docket ID No. EPA-R06-OAR-2015-0189

Dear Mr. Donaldson:

Domtar A.W. LLC's Ashdown Mill is preparing comments on U.S. EPA's proposed Federal Implementation Plan ("FIP") for the mill. The Ashdown Mill requests a limited extension of the comment period for an additional 45 days for the purpose of allowing it to complete modeling work to determine if the imposition of the BART FIP is justified as the assumed visibility improvements appear to be within the CALPUFF margin of error as defined by the United States Court of Appeals for the Ninth Circuit in *Nat'l Parks Conservation Ass'n v. U.S. EPA*, No. 12-73710 (9th Cir. June 9, 2015).

The requested extension is limited in scope to comments addressing the CALPUFF model for the Ashdown Mill. Other comments on the proposed FIP will be submitted by July 15, 2015.

On June 9, 2015, the Ninth Circuit Court of Appeals in *Nat'l Parks Conservation Ass'n* rejected the BART FIP for the Colstrip 1 and 2 facilities in Montana. One of the basis for the decision was the margin of error of the CALPUFF model and the lack of substantial assurance of any improvements in visibility. The Ashdown Mill is currently conducting its own detailed analysis showing that, like the Colstrip 1 and 2 facilities, the model predicted visibility improvement associated with the proposed Ashdown Mill BART FIP is in the margin of error of the CALPUFF model. Since the *Nat'l Parks Conservation Ass'n* decision was issued late in the comment period (June 9, 2015), the Ashdown Mill needs this limited and focused extension in order to complete all of the modeling work and submit it to the Agency.

The requested extension is of limited scope and is for the purpose of submitting to U.S. EPA essential information on a significant aspect of the proposed BART FIP for the Ashdown Mill. Based on the initial modeling work, we anticipate showing that the BART FIP for the Ashdown Mill will not lead to any reasonably anticipated visibility improvements as the purported improvement is beyond CALPUFF's ability to predict with confidence. Not allowing the limited extension will arbitrarily prevent the

Mr. Guy Donaldson

Page 2

Ashdown Mill from submitting full and complete comments on the proposed BART FIP and not allow the Agency to fully address all issues associated with the proposed BART FIP for the Ashdown Mill.

If you have any questions, please contact me at Annabeth.Reitter@domtar.com or 715-459-9257.

Sincerely,

Annabeth Reitter

RE: 17-1276 State of Arkansas v. EPA, et al

Dear Counsel:

We have received a petition for review of an order of the Environmental Protection Agency in the above case, together with a check in the sum of \$500 for the docket fee. Receipt for docketing fee will be sent through the mail.

This case has been consolidated with the following previously docketed appeals:
16-4270, 4296, 4298, 4300, 4302, 4304, 4309, & 4298.

Counsel in the case must supply the clerk with an Appearance Form. Counsel may download or fill out an [Appearance Form](#) on the "Forms" page on our web site at www.ca8.uscourts.gov.

The petition has been filed and docketed. A copy of the petition is hereby served upon the respondent in accordance with Federal Rule of Appellate Procedure, 15(c).

Your attention is invited to the briefing schedule pertaining to administrative agency cases, a copy of which will be sent under separate Notice of Docket Activity. The clerk's office provides a number of practice aids and materials to assist you in preparing the record and briefs. You can download the materials from our website, the address of which is shown above. Counsel for both sides should familiarize themselves with the material and immediately confer regarding the briefing schedule and contents of the appendix.

On June 1, 2007, the Eighth Circuit implemented the appellate version of CM/ECF. Electronic filing is now mandatory for attorneys and voluntary for pro se litigants proceeding without an attorney. Information about electronic filing can be found at the court's web site

www.ca8.uscourts.gov. In order to become an authorized Eighth Circuit filer, you must register with the PACER Service Center at <https://www.pacer.gov/psco/cgi-bin/cmecf/ea-regform.pl>. Questions about CM/ECF may be addressed to the Clerk's office.

CLERK OF COURT

PETITION FOR REVIEW

Pursuant to Section 307 of the Clean Air Act, 42 U.S.C. 7607, and Rule 15 of the Federal Rules of Appellate Procedure, the State of Arkansas hereby petitions this Court for review of the final action of the United States Environmental Protection Agency and Cynthia McCabe, in her official capacity as Acting Administrator thereof, constructively denying Arkansas's Petition for Reconsideration and Request for Administrative Stay of the rule entitled "*Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate*

RECEIVED

FEB - 6 2017

U.S. COURT OF APPEALS

EIGHTH CIRCUIT

Visibility Transport Federal Implementation Plan; Final Rule.” 81 Fed. Reg. 66332 (Sept. 27, 2016).¹ A copy of Arkansas’s petition is attached as Exhibit A.

Pursuant to 42 U.S.C. 7607(b), jurisdiction and venue for this petition are proper in this Court. Arkansas, on behalf of the Arkansas Department of Environmental Quality, submitted its petition on November 22, 2016 and requested a response within seventy (70) days of receipt of the petition. Arkansas informed EPA that, due to the immediate harm resulting from the Final Rule, failure to respond to the petition would be deemed a constructive denial of the same. Therefore, on January 31, 2017, EPA constructively denied Arkansas’s Petition for Reconsideration and Request for Administrative Stay and this petition for review is timely filed before this Court.

¹ Arkansas previously filed a petition for review of that rule. That petition for review is currently pending as *Arkansas v. EPA*, No. 16-4270 (consolidated).

Respectfully submitted,

LESLIE RUTLEDGE

Interstate Visibility Transport)
Federal Implementation Plan;)
Final Rule)

**PETITION FOR RECONSIDERATION AND REQUEST FOR
ADMINISTRATIVE STAY**

I. Introduction

Pursuant to Section 307 of the Clean Air Act (“CAA”),¹ the Arkansas Department of Environmental Quality (“ADEQ”) submits this Petition for Reconsideration requesting that the Administrator of the U.S. Environmental Protection Agency (“EPA”) convene a proceeding for reconsideration of the final rule, “Promulgation of Air Quality Implementation Plans; State of Arkansas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan; Final Rule” (“Regional Haze FIP”).² The ADEQ also requests that the agency immediately stay the Arkansas Regional Haze FIP pending completion of its reconsideration of the final rule. Absent a stay, implementation of the rule will

¹ 42 U.S.C. § 7607(d)(7)(B).

² 81 Fed. Reg. 66332 (Sept. 27, 2016) (hereinafter “Arkansas Regional Haze FIP” or “FIP”).

require expensive and unnecessary expenditures by utilities within Arkansas which will, ultimately, be borne by electric consumers.

Given the important issues raised by this petition, the EPA should immediately contact the ADEQ to discuss an appropriate schedule and process for reconsideration with an administrative stay in place. In the event the EPA has neither granted the petition nor made alternative arrangements with the consent of the ADEQ to establish a schedule for reconsideration within seventy (70) days of receipt of this request, such inaction will be deemed a denial of the petition.

II. The State raises objections that support reconsideration of the Regional Haze FIP.

The Clean Air Act requires the EPA to convene an administrative proceeding for reconsideration of a rule if a party raising an objection to the rule demonstrates to the EPA that: 1) it was impracticable to raise the objection during the comment period, or that the grounds for such objection arose after the comment period but within the time specified for judicial review; and 2) the objection is of central relevance to the outcome of the rule.³ The objections raised in the sections below are of central relevance to the outcome of the final Regional Haze FIP. Considering the new information presented below, the EPA should reach a different outcome in the rulemaking. This new information provides substantial support for revision of the Regional Haze FIP.

³ 42 U.S.C. § 7607(d)(7)(B).

- a. The EPA should reconsider emission controls on Independence in light of recent IMPROVE monitoring data which shows that Arkansas has already achieved the amount of progress required for this planning period.**

The EPA believes that the reasonable progress four-factor analysis requires additional controls for the Entergy Independence Power Plant (“Independence”).⁴ However, the EPA should reconsider whether controls on Independence are necessary under the Clean Air Act because 2015 monitoring data shows that Arkansas is currently meeting the reasonable progress goals set in the FIP and will continue to meet those goals for remainder of the first planning period.⁵ Therefore, further controls on Independence are not necessary to achieve reasonable progress.

It was impracticable to raise this objection during the public comment period for two reasons. First, the 2015 monitoring data were not available at the time the draft rule was released. Since the close of the comment period for the proposed Regional Haze FIP on April 8, 2015, measured concentration data for January 2015 through September 2015 from the IMPROVE network of Class I Federal area monitors became available.⁶ This monitoring data is the most recent available and shows that visibility values for both Caney Creek and Upper Buffalo are not only well below the Uniform Rate of Progress but also well below the reasonable progress goals set by the EPA in the Regional Haze FIP.

⁴ 81 Fed. Reg. 66332, 66350.

⁵ Interagency Monitoring of Protected Visibility Environment, accessed at <http://vista.cira.colostate.edu/Improve/>.

⁶ The public comment period was reopened twice in 2016 but each instance was limited to specific portions of the proposal not related to this data.

Second, EPA revised the final reasonable progress goals for this planning period downwards so that it would not have been possible to raise an objection during the comment period regarding actual visibility conditions being below the final reasonable progress goals because both visibility conditions and goals are components of that objection.

Wilderness Area	Disapproved 2008 RH SIP RPG	Proposed FIP RPG	Final RH FIP RPG	2015 Actual Conditions
Caney Creek	22.48	22.27	22.47	20.41
Upper Buffalo	22.52	22.33	22.51	19.96

The Clean Air Act requires each implementation plan to “contain such emission limits, schedules of compliance and other measures as may be *necessary to make reasonable progress.*”⁷ Thus, because the 2015 monitoring data indicates that Arkansas has already achieved the FIP’s reasonable progress goals without additional controls, the controls placed on Independence are not necessary. Additional controls simply cannot be necessary to achieve an amount of progress that has already occurred. The EPA exceeds its statutory authority by including controls on Independence despite evidence that such requirements are necessary to make reasonable progress.

Given the current visibility conditions and final reasonable progress goals, the EPA’s methodology may not accurately predict the visibility improvement

⁷ 42 U.S.C. § 7491 (emphasis added).

resulting from the installation of those controls on Independence even though these controls are purportedly required to meet those reasonable progress goals. EPA used the CALPUFF model to predict the visibility improvement. The EPA's CALPUFF results overstate the visibility improvements to be obtained by reductions in SO_x and NO_x emissions. The margins of error show that the calculations by CALPUFF are sufficiently unreliable to decide whether the controls result in visibility improvement. In Appendix A attached to this petition, the ADEQ includes Comments on the Use of the CALPUFF Model.

b. The EPA should reconsider compliance with the Transport Rule as an alternative acceptable method of compliance with BART for NO_x as a result of a recent rulemaking that increased the stringency of the Transport Rule.

The ADEQ requests that the EPA reconsider NO_x limitations placed on BART-eligible facilities and determine that compliance with the Transport Rule⁸ is acceptable for compliance with NO_x BART. The implementing regulations for the regional haze program allow the State to consider compliance with the Transport Rule as an alternative to controls on BART-eligible facilities.⁹ As this option is available to the states, the EPA should also include this BART-alternative in the Regional Haze FIP for NO_x controls.

This request is particularly compelling in light of the recent update to the Transport Rule because the revised NO_x budget for Arkansas is now lower than it was when the "better than BART" regulation was initially promulgated. However,

⁸ Also known as the Cross-State Air Pollution Rule, or "CSAPR."

⁹ 40 C.F.R. 51.308(e).

it was impracticable for the ADEQ to raise this issue before the end of the comment period because the final rule regarding Transport Rule NO_x budgets was not published until October 26, 2016.¹⁰ As discussed below, this issue is of central relevance to the outcome of EPA's decision in Arkansas's Regional Haze FIP and would likely lead to a different outcome in the rule; therefore, the EPA should open a proceeding to reconsider this issue.

In a letter to the ADEQ dated October 13, 2016, the EPA indicates that it will most likely consider compliance with the Transport Rule as a viable alternative for NO_x under the Regional Haze Rule and will issue a national rule to that effect.¹¹ However, the EPA is not required to wait until an updated national rule goes into effect; the current rule allowing compliance with the Transport Rule as a BART-alternative is still in effect and has withstood legal scrutiny. Indeed, the Eighth Circuit Court of Appeals has upheld the EPA's reliance on this alternative.¹² In *National Parks*, the court found that it was not an abuse of discretion for the EPA to rely on its expertise and determine that compliance with the Transport Rule met the requirements of the regional haze program.¹³ The court agreed with the D.C. Circuit that reliance on BART-alternatives is measured on their ability to ensure

¹⁰ 81 Fed. Reg. 74504 (Oct. 26, 2016).

¹¹ The letter from EPA is attached as Appendix B to this petition.

¹² *National Parks Conservation Ass'n. v. McCarthy*, 816 F.3d 989 (8th Cir. 2016) ("*National Parks*").

¹³ *Id.* at 996.

“reasonable progress.”¹⁴ As stated above, recent monitoring data show that Arkansas is meeting the reasonable progress goals set by the EPA and will continue to do so for the rest of the first compliance period.

Allowing facilities subject to the Transport Rule to comply with that rule in satisfaction of NO_x controls for BART in Arkansas will not sacrifice stringency. The EPA has already determined that the Transport Rule—also known as the Cross-State Air Pollution Rule (“CSAPR”)—is “better than BART.”¹⁵ According to the EPA, the Transport Rule achieves “greater reasonable progress towards the national goal of achieving natural visibility conditions in Class I areas than source-specific...BART in those states covered by the Transport Rule.”¹⁶ The EPA recently finalized a rulemaking which updated the Transport Rule, entitled the CSAPR Update Rule.¹⁷ The CSAPR Update Rule provides a small and more stringent NO_x trading budget than the original CSAPR trading program that the EPA considered to be “better than BART.”

If compliance with the earlier CSAPR trading program in Arkansas achieved greater reasonable progress than BART for NO_x, then the CSAPR Update Rule

¹⁴ *Id.* at 995, citing *Utility Air Regulatory Group v. EPA*, 471 F.3d 1333, 1341 (D.C. Cir. 2006), which reviewed the earlier version of the Transport Rule, the Clean Air Interstate Rule (“CAIR”).

¹⁵ Regional Haze: Alternatives to Source-Specific Best Available Retrofit Technology (BART) Determinations, 77 Fed. Reg. 33,642, 33,648 (June 7, 2012) (“Better than BART Rule”).

¹⁶ *Id.* at 33,643.

¹⁷ Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, 81 Fed Reg. 74504 (Oct. 26, 2016)

must also achieve greater NO_x emissions reductions than necessary for NO_x for BART because the updated NO_x budgets are reduced and more stringent.¹⁸

Thus, based on previous determinations of the EPA, judicial precedent and the increased stringency of the Transport Rule, the agency should open a proceeding to reconsider compliance with the Transport Rule as an acceptable BART-alternative in a program-specific manner for Arkansas. More specifically, the EPA should consider both the original Transport Rule and the CSAPR Update Rule as acceptable methods of compliance with BART for NO_x.

c. The EPA should reconsider the use of low-sulfur coal as BART for SO₂ for White Bluff in light of its recent letter requesting additional information on BART determinations after the close of the comment period.

Since the Regional Haze FIP was published, the EPA authored a letter dated October 13, 2016, which calls into question the agency's decision not to analyze other available control technologies - including existing control technologies - in its BART determinations for the White Bluff and Flint Creek facilities.¹⁹ BART determinations are a central mechanism by which controls are required under the Regional Haze program for this planning period. As a result, the SO₂ BART determination for White Bluff is central to the Regional Haze FIP and, therefore, reconsideration is appropriate.

¹⁸ Compare 81 Fed. Reg. 74504 at 74508 (showing a "12,048" 2017 ozone season NO_x trading budget and "9,210" NO_x trading budget for 2018 and thereafter) with 40 CFR 97.340 (showing a "11,515" 2009-2014 ozone season NO_x trading budget and "9,597" budget for 2015 and thereafter).

¹⁹ See Appendix B.

In its letter of October 13, 2016, the EPA addresses its “preliminary views on supplemental comments regarding a proposed alternative strategy for their White Bluff facility.”²⁰ The letter sets forth the EPA’s official position on additional information necessary to address a five factor analysis for White Bluff based on Entergy’s comments. Among the information requested, the EPA asks for an “Evaluation of DSI as Interim Control.” The EPA appropriately points out that the “BART guidelines require that a subject-to-BART source install and operate the best available emission reduction technology based on the five statutory factors” and states that “it is necessary to consider whether there are additional SO₂ control measures [for White Bluff]. . . that constitute BART.”²¹ Although the EPA’s request is regarding a specific proposal outside of the comment period, the EPA’s position that Arkansas must perform an additional analysis needed for controls that were not considered by the EPA, calls into question whether the EPA, which steps into the shoes of the state, was also legally required to perform a wider range of analysis of possible emissions controls for its own SO₂ BART determination for White Bluff. The EPA’s request for additional information related to SO₂ controls for White Bluff outside of the comment period should necessitate the reconsideration of low-sulfur coal as BART.

In particular, this new information about the EPA’s position on SO₂ for White Bluff should lead the EPA to reconsider other options that include the EPA’s stated criteria for possible controls for SO₂ for White Bluff including having “a relatively

²⁰ See Appendix B at 1.

²¹ *Id.* at 2.

low capital cost” and whether the controls would “be effective if operated for a short period of time,” which is appropriate due to the short remaining time in the first planning period.

The ADEQ requests the EPA reconsider its SO₂ BART determination for White Bluff and include an analysis for controls that would also have a “low capital cost” and would be effective “for a short period of time” – the use of low sulfur content coal tied to an appropriate corresponding emission rate. The ADEQ urges the EPA to undertake a thorough reconsideration of low sulfur content coal using the five factors resulting in a determination of that emission control as BART. In Appendix D attached to this petition, the ADEQ includes considerations for a five-factor analysis that supports a BART determination for low-sulfur coal when taking into consideration the remaining time in this planning period, as well as certain errors in the EPA’s BART determination for White Bluff.

III. Basis for Immediate Administrative Stay

a. The request meets the standard for an administrative stay.

The EPA Administrator is authorized to stay the effective date of its actions “when justice so requires.”²² The Administrator makes this determination by considering the same factors applied to a request for judicial stay. Those factors are: 1) whether the petitioner is likely to prevail on the merits of the appeal; 2) whether the petitioner is likely to suffer irreparable harm in the absence of a stay; 3) whether it is in the public interest to stay the rule; and 4) whether a stay will

²² 5 U.S.C. § 705.

cause harm to other parties. As proven by the analysis below, justice compels the Administrator to stay the Regional Haze FIP.

b. The State is likely to succeed on the merits of a challenge to the Regional Haze FIP.

Much of the Regional Haze FIP is arbitrary, capricious and without a basis in the law and the State has a strong likelihood of success on the merits of a challenge. The ADEQ does not waive any arguments not raised in this section. The following is not an exhaustive list of the legal flaws in the Regional Haze FIP but, rather, an example of some of the most glaring errors in the rule.

1. The EPA is arbitrary, capricious and without a basis in the law in applying emissions controls to BART-eligible facilities. Some of the emissions controls will not be implemented until after the end of the first planning period²³, a requirement that was questioned by the Fifth Circuit in reviewing a stay request for the Texas Regional Haze FIP.²⁴ In addition, the EPA reduces the time for compliance for other controls without any basis in the record.²⁵
2. The EPA ignored the fact that Arkansas is below the Uniform Rate of Progress (“URP”) in meeting background visibility by 2064. EPA does not explain why it chose to ignore the facts and insisted additional controls were necessary to achieve “reasonable progress.” In combination with the IMPROVE monitoring data discussed above, the ADEQ is very likely to succeed in arguing that additional controls are not necessary to achieve reasonable progress toward background visibility.
3. The EPA has not justified the alleged benefits of the Regional Haze FIP in relation to the costs of compliance. The data in the record demonstrate that the required controls offer no appreciable visibility improvement. Without perceptible visibility improvement,

²³ For example, compliance with SO₂ controls for White Bluff Units 1 and 2 must be met three (3) years after the effective date of the rule, which will be after the end of the first planning period in 2018. See 81 Fed. Reg. 66332, 66335 (Sept. 27, 2016).

²⁴ *Texas v. EPA*, 829 F.3d 405, 429-30 (5th Cir. 2016)

²⁵ See 81 Fed. Reg. 66332, 66342 (Sept. 27, 2016).

the EPA cannot justify the significant costs of compliance – costs that will be passed on to electric ratepayers in Arkansas. The EPA clearly ignores the Supreme Court’s ruling in *Michigan v. EPA*²⁶.

c. An administrative stay will prevent irreparable harm to ratepayers of Arkansas and is in the public interest.

Without an administrative stay of the Regional Haze FIP, the rule will mandate controls that are both unnecessary and costly, imposing billions of dollars in total economic costs without the requisite evaluation of the impact of the controls on visibility improvement in Class I federal areas.

Implementation of the rule as written will inflict irreparable harm upon the Arkansas ratepayers who will ultimately pay for the controls required by the facilities regulated by the rule under the FIP. Entergy Arkansas filed comments estimating that the installation of scrubbers on Independence and White Bluff will cost roughly \$1 billion each.²⁷ Under Arkansas law, the capital costs such as those for installation of emissions controls required by federal law may be passed on to ratepayers.²⁸

The public interest favors the granting of stay because Arkansas has already achieved the reasonable progress goal for this period and excess controls would not further the purpose of the regional haze program. The Regional Haze program grants the EPA the authority to promulgate regulations, including FIPs, that

²⁶ 576 U.S. ___, 135 S.Ct. 2699 (2015).

²⁷ See Entergy comments of August 7, 2015 at p.4; Exhibit B (For White Bluff, the “total capital investment to install dry [scrubbers] was estimated to be “\$1,072,370,000.”), found at <https://www.regulations.gov/document?D=EPA-R06-OAR-2015-0189-0166>.

²⁸ See Ark. Code Ann. § 23-4-501 *et seq.*

“contain such emission limits, schedules of compliance and other measures as may be *necessary to make reasonable progress*.”²⁹ As has been demonstrated by the recent IMPROVE monitoring data, the EPA has no legal basis for mandating additional controls because reasonable progress, as measured by the reasonable progress goals for this planning period, has already been achieved. Therefore, the imposition of emissions controls in excess of this statutory authority are unnecessary and will burden the state’s ratepayers with costs passed on from impacted utilities for the installation of controls that are wholly without a basis in law or fact. It is in the public interest to stay the rulemaking because the high costs of the FIP would unduly burden Arkansas ratepayers without providing an appreciable benefit and in a manner that exceeds the EPA’s authority under the Clean Air Act.

d. An administrative stay will not cause harm to other parties.

A stay of the Regional Haze FIP will not cause harm to the EPA or other parties. As stated above, Arkansas is currently making reasonable progress toward background visibility conditions in its two Class I Federal areas—without any additional controls. Additionally, this progress is projected to continue through 2018 and likely beyond. An administrative stay of the Regional Haze FIP will not slow this progress and will not negatively impact visibility within Class I Federal areas affected by Arkansas sources.

²⁹ 42 U.S.C. § 7491.

IV. Conclusion

For the foregoing reasons, the EPA should open a proceeding to reconsider its decision regarding the Arkansas Regional Haze FIP and should immediately stay the rule.

Comments on the Use of the CALPUFF Model in the US Environmental Protection Agency's Federal Implementation Plan for the Regional Haze Rule in Arkansas

Prepared by:

Gale F Hoffnagle, CCM, QEP

TRC Environmental Consultants

November 18, 2016

INTRODUCTION

The focus of these comments is on the scientific support for US Environmental Protection Agency's (EPA) reliance on small changes in CALPUFF visibility model calculations and results to make policy decisions related to sulfur oxides (SOx) and nitrogen oxides (NOx) emissions controls necessary to reduce visibility impacts on Class I areas in Arkansas. EPA contends in its proposed Federal Implementation Plan (FIP) that modeled visibility improvement numbers on the order of or less than 1 deciview down to 0.002 deciviews in the modeling analysis are sufficient to impose additional controls on power plant units. However, EPA (at Page 2009 of the proposed Utah FIP), admits that "*most people can detect a change in visibility at one dv (deciview)*".

These comments are meant to challenge the scientific integrity of EPA assertions and calculations in the final FIP regarding the CALPUFF-modeled visibility improvement analyses.

MARGIN OF ERROR

Inert Transport

Knowing the range of error for a CALPUFF modeled dv result is important in understanding the relevance of the results. For instance, if CALPUFF says that the visibility will improve by 0.085 dv, what is the range (margin) of error in that model result? Could the range be 0.2 dv to -0.1 dv (no improvement)? To understand how faithfully CALPUFF reproduces actual

G. Hoffnagle Comments, November 2016 1

results we must look to the field experiments comparing CALPUFF³ (version 5.8 as used by EPA) to measured results. The most comprehensive comparisons of CALPUFF with long range transports experiments was prepared for EPA¹ in 2012.

The margin of error is technically determined by multiplying the central value by the standard deviation of multiple values at some confidence level. It is expected that the central value of the measured data and the central value of the modeled results are the same and that the range of modeled error can reasonably be determined by a simple formula. What is immediately apparent by looking through the experiments is that CALPUFF is always biased high using the CALPUFF version (2005, Version 5.8.4) which is cited in the BART Guidelines and used rigorously by EPA in all the BART SIP/FIP work. The studies are presented in Attachment A. There are two issues to contend with, the bias and the margin of error.

A summary table of the EPA¹ results has been prepared:

Table 1: CALPUFF Mean Normalized Bias and Normalized Mean Square Error

Comparisons to Field Studies				
		Maximum Observed Percent MNB/NMSE		Centerline Percent MNB
		MNB	NMSE	
Great Plains				
	100 km,	84%		65%
	600 km.	-75%		-76%
Savannah River				
	100 km.	71%		221%
CAPTEX				
	all receptors 100-1000 km.		41%	
ETEX				
	all receptors 50-1400 km.		320%	

Details of the studies and the results presented in Table 1 are contained in Attachment A.

In summary, all of these comparisons to field experiments show is that CALPUFF has a bias for over predicting maximum concentrations which is at least 71% and a margin of error of

at least 41% around that bias central value. So, as an example, if CALPUFF estimated a visibility reduction of 0.085 Dv, then it is likely that the actual the margin of error is between 0.085 to -0.085 Dv. There is thus the opportunity in the margin of error that the change in Deciviews is imperceptible. The better expression is in Inverse Megameters (Mm^{-1}), because the total extinction goes from 23.05 Mm^{-1} to a range from 19.01 to 9.56 Mm^{-1} .

Table 2: Example Calculation of the Margin of Error

	98% Modeled		Correct for Bias (71%)		Margin of Error (Mm^{-1})		Margin of Error (Dv)	
	Mm-1	Dv	Mm-1	Dv	+41%	-41%	+41%	-41%
Without Control	23.250	8.437	13.596	3.072	19.171	9.643	6.508	-0.364
With Control	23.053	8.352	13.481	2.987	19.009	9.561	6.423	-0.449
Difference	0.197	0.085	0.115	0.085	0.162	0.082	0.085	-0.085

But, all of these evaluations of CALPUFF against field data are from experiments with chemically inert tracers. There was little to no atmospheric chemistry occurring in any of these experiments. So it only reveals the margin of error associated with getting the molecule of SOx or NOx to the Class I area, not whether it is now a sulfate or nitrate.

Atmospheric Chemistry

To address the margin of error associated with the modeling of the atmospheric chemistry involved in the visibility calculation, comparisons of the modeled visibility versus the measured visibility must be used. This relatively straightforward comparison has not been used by EPA in any of the BART actions which they have undertaken. EPA simply states that the Guidance requires the use of the 2005 version of CALPUFF and that its answers can be relied upon to make decisions regarding BART controls and the visibility improvements are *reasonably anticipated*.

In visibility modeling measured versus modeled comparisons should use the IMPROVE ² measured data. On every third day IMPROVE measures the particulate matter which causes visibility impairment and calculates the total extinction and the portions of that extinction due to many types of particles, most especially including nitrates. Nitrate chemistry is the most important to the BART process because in almost every case EPA insists on requiring NO_x reduction through control technology. Because the modeling requires making a daily 24-hour average estimation there is a one-to-one correlation of measured and modeled on every third day. There is, arguably, some offset for travel time from source to park and this occurs around midnight each day. An example which has been studied extensively ³ is two coal fired power plants which are less than 100 kilometers west of the Mt. Zirkel Wilderness Area in Colorado. Figure 1 shows the geographic situation.

FIGURE 1: Geographic Layout between Power Plants and Mt. Zirkel

Craig Station is approximately 83 kilometers from the Mt. Zirkel IMPROVE site and Hayden Station is approximately 50 kilometers away in nearly the same direction where it is

anticipated that both facilities would impact on some of the same days. EPA, by the way, almost never models the impacts of multiple facilities when determining BART.

Because the wind doesn't always blow from the WSW direction, the comparison should be made on the worst case days of modeled impact at Mt. Zirkel. Using modeling produced by Colorado ⁴ the 25 worst case modeled days were matched with days of measured data at Mt. Zirkel resulting in 10 days in 2002. Figure 2 shows a comparison of total extinction for those 10 days when the only modeled contributor to visibility extinction is Craig Station.

FIGURE 2: Predicted vs Observed Total Extinction: Craig Station to Mt. Zirkel Wilderness 2002

Note: This has been revised based on the analysis of previous results in Docket EPA-R06-OAR-2015-0189-0222

The modeled results exceed the observed in Figure 2 by 17% (the bias) and the margin of error is 38%. That result assumes that Craig Station is the only contributor to extinction at Mt. Zirkel, which clearly is not true. When Hayden Station is added to the evaluation, the modeled exceeds the observed by 61% (the bias) and the margin of error is 132%. There are, of course, G. Hoffnagle Comments, November 2016

other power plants and oil and gas sources in the area that contribute to the measured data which are not accounted for in the model and thus the over prediction and margin of error are actually greater.

The results for total extinction are somewhat in line with the margin of error for non-reactive comparisons made above. That is, over predictions on the order of 71%.

The issues in the BART SIP/FIP debates are, however, the prediction of nitrate extinction due to NOx emissions which EPA seeks to control. Because the model calculates and the IMPROVE data measures nitrates at the parks, a comparison can be made of the nitrate calculation margin of error. Starting again with Craig Station only, the comparison is shown in Figure 3:

FIGURE 3: Predicted vs Observed Nitrate Extinction : Craig Station to Mt. Zirkel Wilderness 2002

Note: This has been revised based on the analysis of previous results in Docket EPA-R06-OAR-2015-0189-0222

Again, this is the subset of the top 10 modeled days for which there is a measurement at Mt. Zirkel versus the modeled nitrate extinction from Craig Station only. The average over prediction (the bias) is 6.44 times the measured extinction, not just 71%. The margin of error grows to 45.5 times the value. This implies that the model is consistently making far more nitrates than are actually measured and has no reasonable ability to predict nitrate concentrations. If Hayden Station is added, the over prediction (the bias) goes to 14.3 times the actual measured.

The reason for the models over prediction is obvious to many atmospheric chemists. EPA insists that the ammonia be set to 1 ppb, no matter the time of year. Almost all of the occurrences of high extinction due to the power plants occur in the winter when ammonia concentrations in the atmosphere are low. There is one exception (May 16, Julian day 137). When the atmosphere is cold enough to make nitrates from NO_x, there is little ammonia available to do so in the winter months. Also, SO_x in the plumes preferentially uses the ammonia. EPA has insisted that background ammonia concentrations be kept at 1 ppb throughout the year and be available to every NO_x or SO_x molecule that is modeled. The use of an annual concentration for ammonia is curious since many measurements of ambient air ammonia show concentrations in the range of 0.1 ppb in the winter months and EPA uses monthly average concentrations of water vapor and hourly measures of ozone in its modeling.

Summary

The bias for the use of the 2005 version of CALPUFF in evaluating concentrations and thus extinction in National Parks and Wilderness Areas is on the order of 71% over prediction (the bias) for atmospheric dispersion process and at least a factor of 6.44 times actual extinction (the bias) for winter time nitrate formation from emission sources. The margin of error is 41%

for the inert transport and 37% for total extinction. For nitrates specifically the margin of error is 45 times the value.

Comparing Model Results and Applying the Margin of Error

In rejecting Arkansas's BART SIP, EPA chose to add the Independence Power Plant to the facilities needing controls. EPA primarily relies on just one model result to test the results of its controls, the 98% of potential visibility impacts in the Parks. That means the impacts on just 7.3 days (8th highest impact day). This, of course is the most stringent test and is not derived from the focus of the BART rule on the best 20% of days and the worst 20% of days.

The Independence Plant is 180 kilometers from the Upper Buffalo Wilderness Area and 277 kilometers from Caney Creek Wilderness Area. Referring again to the tracer studies on the transport and dispersion of CALPUFF 5.8 shown in Table 1, the bias and margin of error for the model at these distances is substantially worse than it is at 100 kilometers. Technically the bias and margin of error are larger at these distances and the EPA deciview results are even less reliable.

For the Arkansas FIP EPA CALPUFF model results⁵ for the Independence Plant, Table 3 shows the effect of considering the transport/diffusion margin of error assuming the calculation is at 100 kilometers. The reductions in predicted deciviews account only for the bias and margin of error in the transport and diffusion of gases to the Wilderness Areas and do not account for the errors in atmospheric chemistry.

**Table 3: Apply Transport and Diffusion Margin of Error to EPA Independence Results
(EPA final Rule Table 14)**

Final Rule	Model Predicted Baseline		With FGDD		FGDD Improvement	
	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	12.86	2.51	11.52	1.42	1.33	1.10
	12.54	2.26	11.15	1.09	1.39	1.18

G. Hoffnagle Comments, November 2016 8

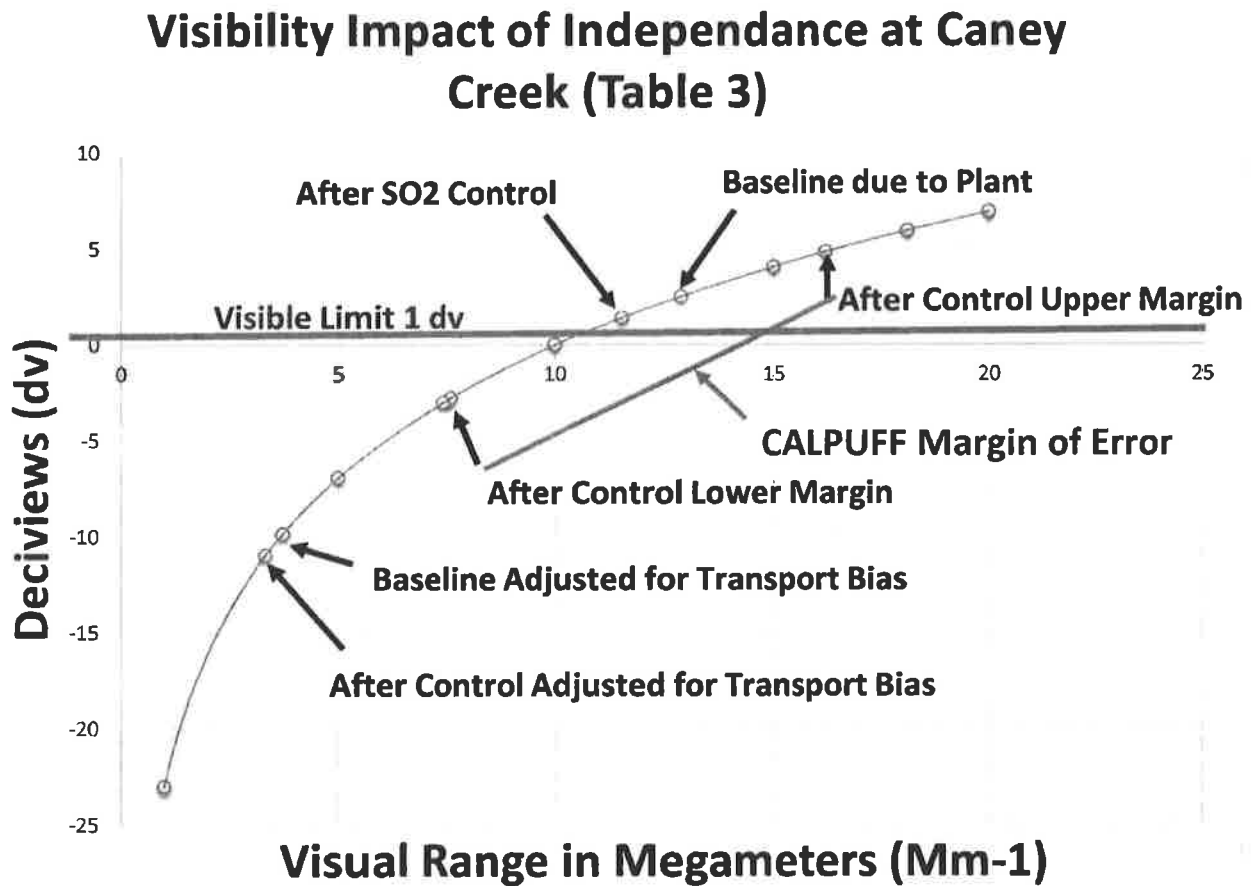

Subtract Bias of 71%						
Bias	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	3.73	-9.87	3.34	-10.96	0.39	not visible
	3.64	10.11	3.23	-11.29	0.40	not visible
Margin of Error of +41%						
Plus Margin	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	18.13	5.95	16.24	4.85	1.88	1.10
	17.68	5.70	15.72	4.52	1.96	1.18
Margin of Error of -41%						
Minus Margin	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	7.58	-2.76	6.80	-3.86	0.79	not visible
	7.40	-3.01	6.58	-4.19	0.82	not visible

Table 3 shows the EPA Table 14 results in the first set labeled **Final Rule**. It shows EPA's calculation of visibility improvement of 1.1 and 1.18 deciviews when using a dry FGD. I have used two significant figures to the right of the decimal point, but even that is more places than valid by the calculation error. The second set of calculations is an evaluation using the bias of CALPUFF and is labeled **Bias**. This shows that bias brings the calculation of an impact of both the base case impact on the Wilderness Areas to well below zero deciviews and no visually perceptible impact. In order to show the margin of error issue, I will ignore for the moment that the bias takes the calculation of any visible impact. The third set is applying the margin of error on the plus side and is labeled **Plus Margin**. The plus margin results in impacts of 4.85 and 4.52 Mm-1 of extinction. The last set is the negative margin and is labeled **Minus Margin**. It shows

that the margin of error includes no visible impact at all. When the change in visibility is too small (below zero dv) it is labeled “not visible”.

To aid in visualizing the results in Table 3 they are reproduced in Figure 4.

FIGURE 4: Presentation of the Results in Table 3

The Table 3 results show that correcting for dispersion and transport bias would result in no visibility impact from the Independence Plant. The Table 3 results show that utilizing the transport and diffusion margin of error (without accounting for the bias), the EPA CALPUFF model results show too large a margin of error to conclude that that requiring dry FGD on the

Independence Plant would assure an improvement in visibility. The margin of error is from 4.85 Mm-1 to not visible at all.

The bias and margin of error for the EPA CALPUFF modeling for Independence Plant for the effectiveness of NOx controls is related to the formation of nitrates from the emissions of NOx. The results can be evaluated in the same way. EPA has chosen, in order to maximize the effect of reductions in NOx emissions to use a different baseline for calculation of the controls benefit. This is highly unusual since it then changes the dates, times and locations of the 98% frequency of impact on the Class I areas. Because of this change I have had to re-evaluate the transport and diffusion errors before adding the atmospheric chemistry errors. These results are presented in Table 4.

Table 4 demonstrates that when you consider the transport and diffusion bias to the EPA calculated NOx control analysis all results fail to have a visible impact. The atmospheric chemistry bias for total emissions and for nitrate emissions discussed above are applied separately at that line in the Table.

Table 4: Apply Transport, Diffusion and Atmospheric Chemistry Margin of Error to EPA Results (EPA Final Rule Table 15)

Final Rule	Model Predicted Baseline		With NOx Controls		NOx Improvement	
	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	12.25	2.03	11.70	1.57	0.55	0.46
	12.22	2.00	11.98	1.81	0.24	0.20
Transport Bias and Margin Plus Margin						
	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek Upper Buffalo	5.01	-6.91	4.78	-7.37	0.22	not visible
	5.00	-6.94	4.90	-7.14	0.10	not visible

Minus Margin	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv

Chem + Trans	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv	$\Delta Mm-1$	Δdv
Caney Creek	3.55	-10.35	3.39	-10.81	0.02	not visible
Upper Buffalo	3.54	-10.38	3.47	-10.57	0.01	not visible

Other Evidence

The most compelling evidence of the bias and margin of error would come from a direct comparison of the modeled results to actual measurements at the Class I areas. It is a sign of the unscientific approach to visibility which EPA has undertaken that they never compare their model predictions to measured data. The IMPROVE network has been taking measurements of the nitrates and sulfates at many Class I areas including the Caney Creek Wilderness Area and Upper Buffalo Wilderness Area for decades, including the years 2001, 2002 and 2003 which are the subject of the modeling. The measurements are 24 hour averages, just like the model results and so one-to-one comparisons can be made. It should be noted that the IMPROVE margin of error is on the order of 3% for the equation they developed to calculate deciviews from measured particulate concentrations. It is beyond scientific understanding why EPA does not do or require this analysis model comparison analysis in the BART process.

Fortunately for this Arkansas case, this kind of measured to model comparison has been done. Trinity Consultants⁶ prepared for EAI the model results at the Lake Catherine Plant. Caney Creek is approximately about 100 kilometers west of Lake Catherine (the ideal distance for the margin of error derived above) and approximately 160 kilometers southeast of Upper Buffalo. The comparisons are shown on Trinity Figures 4-1 through 4-6 of the report and show that the Lake Catherine Plant makes infinitesimal contributions to the 20% worst case days at the two Wilderness areas. This is compared to the EPA methodology CALPUFF model results which estimate that Lake Catherine makes average contributions on the 20% worst case days of 28.60 Mm⁻¹ (dv=1.39). The bias is evident and the margin of error is 1.16 dv at Caney Creek and 0.93 at Upper Buffalo.

CONCLUSION

The bias and margins of error for CALPUFF, both the transport and diffusion error and the chemistry error, have been applied to various results of EPA CALPUFF BART modeling for the Arkansas Regional Haze SIP and EPA FIP. The CALPUFF results considering the bias overstates the visibility improvements to be obtained by reductions in SO_x and NO_x emissions. The margins of error show that the calculations by CALPUFF are sufficiently unreliable to decide whether the controls result in visibility improvement. Improvements in visibility for the Independence Plant are not visible once the bias and margin of error of the CALPUFF modeling are taken into account. In addition, predicted improvements are below 1 Dv, the limit of human perceptibility. Adding controls to the Independence Plant will not lead to significant or measureable improvements in visibility in the Wilderness Areas.

Attachment A

Basis for Adopting CALPUFF in the BART Rules:

The US EPA adopted, in November 9, 2005, changes to the Guideline on Air Quality Models (40 CFR part 51, Appendix W) which identified the modeling system called CALPUFF version 5.8 (originally developed for the California Air Resources Board) as the “preferred” model for Long Range Transport (LRT), i. e. any distance beyond 50 kilometers from the source. Nearly simultaneously, July 9, 2005, EPA finalized the BART Guidance (40 CFR part 51, Appendix Y) which allowed the use of the CALPUFF version 5.8 modeling system in assessing visibility improvements at Class I areas for BART eligible sources. These actions were based on nearly 10 years of work, mostly by the Federal Land Managers, to determine if CALPUFF was appropriate for the analysis.

The basis of these adoptions was comparisons of CALPUFF results to measured data from 4 long range transport (LRT) experiments. Each of these experiments used inert tracers and thus evaluated the transport and diffusion aspects of CALPUFF. The tests were summarized in the report “Interagency Workgroup on Air Quality Modeling (IWAQM) Phase 2 Summary Report and Recommendations for Modeling Long Range Transport Impacts”, EPA-454/R-98-019, December 1998. EPA also produced a document “A Comparison of CALPUFF Modeling Results to Two Tracer Field Experiments”, EPA-454/R-98-009, June 1998. This document dealt with the Savannah River and Great Plains studies. The outcomes of these model comparisons are as follows:

1. Savannah River Laboratory Tracer Study: A single 6 hour tracer release was measured along an arc of measurement points 100 kilometers from the release. The terrain was flat and heavily wooded so the release was from an elevated tower. The CALPUFF 5.8 result was 35% higher than the measured concentration of the released gas and 20° off in the wind direction and much too narrow a plume.

Figure 1: Savannah River Results at 100 Kilometers

Dashed line represents CALPUFF version 5.8 results which require use of P-G dispersion

2. Idaho Falls Tracer Study: A single 3 hour release was measured along three sampling arcs at 3, 48 and 90 kilometers. The terrain was flat rangeland.
 - a. At 3 kilometers the CALPUFF 5.8 result was 9 times too high and 10°
 - b. At 48 kilometers the CALPUFF 5.8 result was 10% too high, 20° off in wind direction and much too narrow.
 - c. At 90 kilometers the CALPUFF version 5.8 result was 5% too high and 10° off in wind direction and the width was similar.

Figure 2: Idaho Falls Results at 3 Kilometers

Dashed line represents CALPUFF version 5.8 results which require use of P-G dispersion

Figure 3: Idaho Falls Results at 48 Kilometers

Dashed line represents CALPUFF version 5.8 results which require use of P-G dispersion

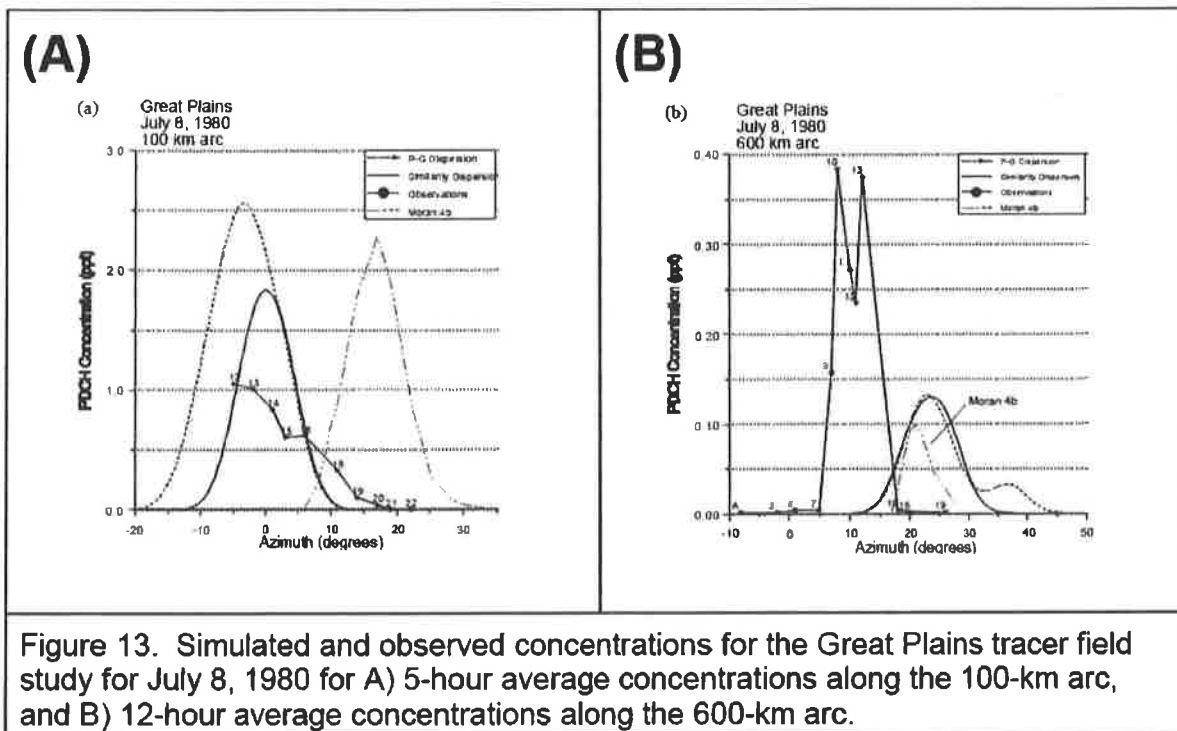

Figure 4: Idaho Falls Results at 90 Kilometers

Dashed line represents CALPUFF version 5.8 results which require use of P-G dispersion

3. Great Plains Tracer Study: A 3-4 hour tracer release from near Oklahoma City was measured at distances of 100 and 600 kilometers. The terrain was flat except for the Ozark Mountains.
 - a. At 100 kilometers the CALPUFF version 5.8 result was 2.5 times the measured data, about right in wind direction but narrower than the plume. There was a second test at 100 kilometers where the CALPUFF version 4.8 results were 2.27 times the measured.
 - b. At 600 kilometers the CALPUFF version 5.8 result was 1/3rd of the measured concentrations, 15° off in wind direction and wider than the plume.

Figure 5: Great Plains Results at 100 kilometer (A) and 600 Kilometers (B)

Dashed line represents CALPUFF version 5.8 results which require use of P-G dispersion

4. Project Mohave Tracer Study: This is the only long term release study used, it had 31 days of emissions in mid-summer. There were several monitors but not an arc like the other studies. After various artificial changes to the model method, CALPUFF version 5.8 results at a single monitor about 100 kilometers away showed various results but tended to follow the measured data fairly closely.

Figure 6: Project Mohave Results at ~100 Kilometers

These were the four long range transport experiments available for comparison to the CALPUFF version 5.8 at the time of adoption. All these experiments lacked the rigor of a truly useful database for making a model comparison. They also suffer from using inert tracers that do not have any atmospheric chemistry and thus only test the ability of the model to get gases from point A to point B. All but one of these comparisons is on flat terrain and thus unlike Utah. Most importantly, these comparisons are not comparisons for calculating deciviews. Despite all of the issues raised by these studies, the IWAQM conclusion was that

“Comparisons were made of CALPUFF simulated dispersion with near surface concentrations collected during several tracer field studies, where the transport distances were of the order 50 to 300 km. ...The CALPUFF modeling system is recommended in place of the MESOPUFF II modeling system for a number of reasons..... The IWAQM recommends the CALPUFF modeling system for use as a refined long-range transport and dispersion modeling technique for characterizing reasonably attributable pollutant impacts from one or a few sources.”

From the accumulated tracer-study results, I could only conclude that at 100 kilometers CALPUFF version 5.8 was 35%, 5% or 250% too high, an average of 96% too high. The mean error rate for all four tests was 96%. At 600 kilometers it vastly underestimated concentrations. The source of the regulatory use of CALPUFF out to 300 kilometers is the offhand statement G. Hoffnagle Comments, November 2016 20

cited above and not supported by any of the data in the report. There are comparisons to data at less than 50 kilometers and to other models but none of them tell us anything about the long range transport capabilities of CALPUFF version 5.8.

In addition, as best that could be determined from the Savannah River and Great Plains experiments (Table 2 of EPA-454/R-98-009) at the time there is an error rate of 79% and always greater than the measured concentration. The error rate can be expected to become worse at distances beyond 100 kilometers, but we only know what happens at 600 kilometers where the model is clearly not consistent with the experimental results. The “margin of error” identified in the aforementioned studies is hereafter referred to as the “transport/diffusion margin of error” because these studies measured CALPUFF v. 5.8’s accuracy relative to long-range transport and diffusion.

Activities since Adoption of the BART Guidance:

There have only been two changes to the BART Guideline’s version of the CALPUFF modeling system since its adoption in 2005. Version 5.8 was actually adopted on July 29, 2007 after some initial bug fixes. But even that version had bugs that were pointed out soon afterward to the EPA Air Quality Modeling Group (AQMG) of the EPA Office of Air Quality Planning and Standards (OAQPS) which is responsible for the Guidelines and thus the preferred versions of the models. Finally, on December 4, 2013 (6 and ½ years later) EPA approved bug fixes to create version 5.8.4 used in the Utah modeling. No other enhancements to CALPUFF were allowed. Separately, on August 27, 2012 AQMG made a change to the preferred version of CALPOST to version 6.221 which allowed the use of the revised IMPROVE equation for visibility and has been used in the Utah modeling. No changes to CALPUFF itself occurred at that time.

The owners of CALPUFF (first TRC and then EXPONENT) have prepared more advanced versions of CALPUFF that have not been adopted by EPA. The focus of these advancements have been in providing better atmospheric chemistry based on twenty years of advancement in atmospheric chemistry science. AQMG has steadfastly refused to give anything more than lip service to these advancements and yet continuously criticizes CALPUFF for not having advanced chemistry.

In May 2012, EPA released a report entitled “Documentation of the Evaluation of CALPUFF and Other Long Range Transport Models Using Tracer Field Experiment Data”, EPA-454/R-12-003 (Environ Report). It used CALPUFF Version 5.8 (without bug fixes) to

evaluate the data bases cited above and two new ones; 1) the Cross Appalachian Tracer Experiment (CAPTEX) and the European Tracer Experiment (ETEX). CAPTEX covered distances of 100 to 1000 kilometers northeast from the release point in Dayton, Ohio. All of the receptors were in complex terrain crossing the Appalachian Mountains. This is actually more of a test of the meteorological model performance (CALMET) than the concentration model performance (CALPUFF). ETEX covered distances from 50 kilometers to 1,400 kilometers across Europe from a release point in France. Again, the emphasis of the analysis was getting the meteorology model (CALMET) to perform well.

The Environ Report also re-evaluated 2 other LRT models and a plethora of modifications to CALPUFF. The purpose of the report, to analyze CALPUFF performance, was a thinly veiled attempt by AQMG at EPA to replace CALPUFF. That is apparent because in each comparison CALPUFF performed the worst and the bias of the study has been pointed out by many since.

The Environ Report does provide statistical evaluations of the CALPUFF Mean Normalized Bias (MNB), essentially the margin of error, which is the objective of this report. The results can be summarized as follows:

Table 1: Margin of Error for CALPUFF

Comparisons to Field Studies				
		Maximum Observed Percent MNB*		Centerline Percent MNB
Great Plains				
	100 km,	65%		84%
	600 km.	-75%		-76%
Savannah River				
	100 km.	71%		221%
CAPTEX				
	all receptors 100-1000 km.		41%**	
ETEX				
	all receptors 50-1400 km.		320%**	
* Mean Normalized Bias				
**Normalized Mean Square Error

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 6
1445 ROSS AVENUE, SUITE 1200
DALLAS, TX 75202-2733

OCT 13 2016

Mr. Stuart Spencer
Associate Director, Office of Air Quality
Arkansas Department of Environmental Quality
5301 Northshore Drive
North Little Rock, AR 72118-5317

Dear Mr. Spencer:

I am writing today to provide our preliminary views on supplemental comments received from Entergy regarding a proposed alternative strategy for their White Bluff facility. These comments were received on August 8, 2016, well outside the comment period, and therefore could not be considered in our final Federal Implementation Plan (FIP) action, for which we were under a court-ordered deadline of August 31, 2016 (Sierra Club v. Gina McCarthy, No. 4:14CV00643JLH (ED Ark. Western Div. Nov. 3, 2015)). We believe, however, that the alternative plan proposed by Entergy in their comments has potential merit with respect to addressing the best available retrofit technology (BART) requirements for White Bluff, and if the issues identified in the enclosure were to be addressed, could provide the basis for an approvable State Implementation Plan (SIP) revision. If Arkansas believes that Entergy's alternative plan is a more appropriate course, we would be happy to continue to work with you on such a SIP revision that could replace the FIP requirements for the White Bluff units.

Please contact me at 214-665-7548, or Guy Donaldson, of my staff, at 214-665-7242, if you would like to discuss further.

Sincerely,

A handwritten signature in black ink, appearing to read "Mark Hansen".

Mark Hansen
Associate Director for
Air, Multimedia Division

Enclosure

cc: Kelly McQueen
Assistant General Counsel, Entergy

Enclosure:

Entergy's August 8, 2016 letter requests that the sulfur dioxide (SO₂) BART determination for the White Bluff units be either an emission limit of 0.06 lb/MMBtu on a 30 boiler-operating-day rolling average consistent with the installation of dry flue gas desulfurization (dry FGD), or as an alternative to the installation of these controls, a binding requirement to (1) cease coal fired operation at one unit by the end of 2025 and the other unit by the end of 2026 and (2) limit the operation of one unit to a capacity factor of no greater than 50 percent in 2025. In addition, Entergy requests a revised nitrogen oxide (NO_x) BART emission limit of 1,305 lb/hr for periods when the White Bluff units are operating at a low capacity factor. Based on the information provided in the August 8, 2016 comment letter, an approvable SIP revision that includes Entergy's requested BART determinations for White Bluff must also include certain additional information and documentation to fully support those BART determinations. The additional information and documentation that are needed are discussed in the paragraphs that follow.

Enforceable Mechanism

If Arkansas agrees that it would be appropriate to take the alternative approach for White Bluff, the SIP revision must include an enforceable mechanism which requires that Entergy (1) cease coal combustion at White Bluff by the end of 2025 at one unit and by the end of 2026 at the other unit, and (2) limit operation of one unit to a capacity factor of no greater than 50 percent in 2025.

Revised dry FGD Cost Analysis

As part of the BART analysis, a demonstration that dry FGD is no longer cost-effective in light of a shorter remaining useful life for the White Bluff units must be included in the SIP revision. Entergy's August 8, 2016 letter includes an updated BART analysis of the five statutory BART factors. In this analysis, Entergy relies on the cost analysis prepared in 2015 by Sargent & Lundy (2015 Sargent & Lundy cost analysis), and indicates that the cost effectiveness of dry FGD would range from \$10,400 to \$11,800/ton removed at each unit if coal combustion were to cease in 2025 and 2026. As discussed in our Arkansas FIP signed on August 31, 2016, the 2015 Sargent & Lundy cost analysis presents problems that prevented us from using it in our FIP, primarily because it is undocumented. For example, the 2015 Sargent & Lundy cost analysis uses a 2013 Alstom quote as its basis, but the 2013 Alstom quote is not provided in the 2015 Sargent & Lundy cost analysis. This omission prevents us from verifying the scope of work covered in that cost analysis. In addition, certain costs included in the 2015 Sargent & Lundy cost analysis were not documented. An approvable SIP revision that relies on the 2015 Sargent & Lundy cost analysis must include corrections of the issues we identified with that cost analysis, as discussed in our Arkansas FIP. Alternatively, the SIP revision could rely on our revised cost analysis for dry FGD, as presented in our Arkansas FIP, to calculate the cost effectiveness of dry FGD in light of the shorter remaining useful life.

Additionally, in the updated BART five factor analysis provided in Entergy's letter, the cost effectiveness of dry FGD controls was calculated based on an assumption that the annual emissions reductions achieved with dry FGD would be lower if the unit were restricted to operate at a capacity factor of no greater than 50 percent in 2025. Additional explanation of how the annual emissions reductions were calculated and the calculations themselves must be provided to properly support the assumed annual emissions reductions. The updated BART five factor analysis also includes a revision of

the direct variable and fixed operation and maintenance (O&M) costs to reflect operating at a capacity factor of no greater than 50 percent in 2025. The calculations of the revised direct variable and fixed O&M costs must be provided.

Evaluation of DSI as an Interim Control

As discussed in our Arkansas FIP, because section 51.308(e)(1) and the BART guidelines require that a subject-to-BART source install and operate the best available emission reduction technology based on the five statutory factors, it is necessary to consider whether there are any additional SO₂ control measures (beyond the interim SO₂ emission limit of 0.6 lb/MMBtu proposed by Entergy) that constitute BART during the interim period before coal combustion ceases at the White Bluff units. In particular, dry sorbent injection (DSI) has a relatively low capital cost and may be cost effective even if operated for a short period of time. An approvable SIP revision must include a full BART analysis that considers and evaluates DSI to determine if it constitutes BART during the interim period. This evaluation must include the following:

- Evaluation of the feasibility and capability of DSI at the White Bluff units, including the anticipated range of emissions reductions. This may include evaluation of the existing particulate matter (PM) control equipment and any need for potential additional PM control equipment to handle the additional PM load. The BART analysis must include documentation of the need for any additional PM control equipment needed to handle the additional PM load.
- Cost evaluation of DSI and any necessary additional PM control equipment (including supporting documentation) that takes into consideration the remaining useful life of the units.
- Evaluation of the potential visibility benefits of DSI controls.
- Evaluation of any energy and non-air quality environmental impacts of DSI controls.

Entergy's Refined NO_x BART Emission Limit

With regard to appropriate NO_x BART limits, Entergy's letter states that it "has refined its analysis of the proposed NO_x limitation," and determined that a NO_x emission limit of 1,305 lb/hr is achievable and appropriate as NO_x BART for the White Bluff units when they are operated at less than 50 percent of capacity. While we understand Entergy's concerns about not being able to meet an emission limit of 0.15 lb/MMBtu on a 30 boiler-operating-day rolling average when the units are operated at less than 50 percent of capacity, there is no information presented in Entergy's letter to demonstrate that an emission limit of 1,305 lb/hr is sufficiently protective or appropriate when the units are operated at low capacity. In particular, we discussed in our Arkansas FIP that the 1,342.5 lb/hr emission limit Entergy initially requested in the comments submitted during the comment period appeared to be based on the maximum heat input rating for each unit and therefore was not an appropriate emission limit for operation at low capacity. The revised emission limit Entergy requests in the August 8, 2016 letter is only slightly lower. Entergy provided no information demonstrating that this limit would be sufficiently protective or appropriate when the units are operated at low capacities considering that NO_x emissions on a mass basis are expected to be lower when the units are operated at low capacity compared to operation at high capacity. As the Regional Haze Rule requires the identification and evaluation of the highest level of control a particular control technology is capable of achieving (see 64 FR at 35740), additional information must be provided to document and demonstrate that 1,305 lb/hr is appropriate and sufficiently controls NO_x emissions using LNB/SOFA when the units are operated at less than

50 percent of capacity. This additional information could consist of the refined analysis Entergy mentions in page 5 of the supplemental comments attached to the August 8, 2016 letter and/or a vendor guarantee.

Entergy's Updated NO_x Control Costs

Entergy's August 8, 2016 letter provides an updated calculation of the cost effectiveness of NO_x controls that takes into consideration a shortened remaining useful life for the White Bluff units. The updated calculation of the cost effectiveness of NO_x control costs appears to be based on the cost analysis included in Entergy's "Revised BART Five Factor Analysis for White Bluff Steam Electric Station Redfield, Arkansas (AFIN 35-00110)," dated October 2013. As discussed in our FIP proposal (see 80 FR at 18973), that cost analysis of NO_x controls included certain line items that were not documented by Entergy and do not appear to be valid costs under the Control Cost Manual methodology. The updated calculation of the cost effectiveness of NO_x controls must be based on a cost analysis that either properly documents these line items or eliminates them from the total annual cost estimate.

Additionally, Entergy's updated calculation of the cost effectiveness of NO_x controls assumes that the annual emissions reductions achieved would be lower if the unit is restricted to operate at a capacity factor of no greater than 50 percent in 2025. Additional explanation of how the annual emissions reductions were calculated and the calculations themselves must be provided to properly support the assumed annual emissions reductions. In the updated cost analysis, Entergy also revised the direct variable and fixed O&M costs of NO_x controls to reflect operating at a capacity factor of no greater than 50 percent in 2025. The calculation of the revised direct variable and fixed O&M costs must be provided.

CSAPR Better than BART

As discussed in our Arkansas FIP, we proposed and ultimately finalized source specific NO_x BART determinations for Arkansas' electric generating units (EGUs) instead of relying on the Cross State Air Pollution Rule (CSAPR) because at the time of our proposed action, this approach properly accounted for uncertainty in the CSAPR better-than-BART regulation created by ongoing litigation regarding the CSAPR program. This approach was also consistent with Arkansas' earlier decision to conduct source-specific NO_x BART determinations in lieu of relying on CSAPR's predecessor, the Clean Air Interstate Rule, to meet the BART requirements. In addition, after we proposed the Arkansas FIP, the D.C. Circuit issued a July 2015 decision in *EME Homer City Generation v. EPA* upholding CSAPR but remanding without vacatur a number of the Rule's state NO_x and SO₂ emissions budgets (795 F.3d 118 (D.C. Cir 2015)). Arkansas' ozone season NO_x budget is not itself affected by the remand. However, the Court's remand of the affected states' emissions budgets has implications for CSAPR better-than BART, since the demonstration underlying that rulemaking relied on the emission budgets of all states subject to CSAPR, including those that the D.C. Circuit remanded, to establish that CSAPR provides for greater reasonable progress than BART. We are in the process of acting on the Court's July 2015 remand. On September 7, 2016, we finalized an update to the CSAPR ozone season program by issuing the CSAPR Update. This rule addresses the summertime (May – September) transport of ozone pollution in the eastern United States that crosses state lines to help downwind states and communities meet and maintain the 2008 ozone national ambient air quality standard (NAAQS), and also responds to the Court's remand of the Phase 2 ozone season NO_x budgets for 11 states. The CSAPR Update also

promulgates a FIP for Arkansas that establishes an EGU NO_x ozone season emission budget to reduce interstate transport for the 2008 ozone NAAQS. We are in the process of responding to the Court's remand of the Phase 2 SO₂ emission budgets for four states, consistent with the planned response we outlined in a June 2016 memorandum.¹ We expect that the uncertainty created by the D.C. Circuit's remand of the affected states' emission budgets will shortly be resolved. The CSAPR Update does not include determinations or establish any presumptions that compliance with that rule satisfies NO_x BART for EGUs. However, the Environmental Protection Agency's preliminary analysis indicates that CSAPR participation will remain an appropriate BART alternative for all states participating in CSAPR (either by FIP or SIP adoption). We intend to determine whether compliance with CSAPR will continue to be an appropriate BART alternative in another rulemaking soon that takes into account the changes to CSAPR following the July 2015 remand. If EPA finds that CSAPR continues to provide for greater reasonable progress than BART,² the State may submit a SIP revision that includes reliance on CSAPR to satisfy the NO_x BART requirements for Arkansas' EGUs instead of doing source-specific NO_x BART determinations.

Additional Information on Operation After Coal Combustion Ceases

Entergy's August 8, 2016 letter indicates that it anticipates ceasing coal combustion at White Bluff by the end of 2025 at one unit and 2026 at the other unit. A SIP revision that assumes a shorter remaining useful life for the units should include a discussion of the fuel types Entergy anticipates using after coal combustion ceases, including whether there will be a limit on the sulfur content of any fuel oil burned at the units.

¹ https://www3.epa.gov/airtransport/CSAPR/pdfs/CSAPR_SO2_Remand_Memo.pdf

² Alternatively, Arkansas could conduct an analysis that demonstrates compliance with the CSAPR Update for certain EGUs in Arkansas fulfills NO_x BART for those EGUs.

Appendix C

CONSIDERATIONS FOR A REVISED FIVE-FACTOR ANALYSIS FOR LOW-SULFUR COAL AS BART

a. Cost of Compliance

In contrast to Flue Gas Desulfurization, low-sulfur coal would be cost effective over the remainder of the first planning period, which ends in 2018. EPA underestimates certain costs and overestimates emission reductions with respect to installation of scrubbers according to a report prepared for Entergy by engineering firm Sargent and Lundy, LLC (“S & L”).¹ Taken in combination, EPA’s assumptions artificially lower the annual cost and cost-effectiveness (\$/ton reduced annually) estimates. The S & L report estimates that the actual cost-effectiveness for scrubbers would be between \$5,462 – \$6,445 more expensive per ton of SO₂ reduced than EPA’s estimate in the FIP. Due to market conditions for coal and natural gas, Entergy White Bluff has seen a decrease in dispatch that is expected to continue during this planning period resulting in a reduction in annual SO₂ emissions. Units 1 and 2 are currently permitted to emit 45,727.2 tons per year (tpy) SO₂ (10,440.0 lb SO₂/hr) each or 91,454.4 tpy SO₂ (20,880 lb SO₂/hr) combined.² Annual emissions for Entergy White Bluff units 1 and 2 combined from 2008 – 2014 ranged from 31,684 – 37,939 tpy SO₂—less than half of total allowable emissions in their permit.³ Annual emissions from Entergy White Bluff dropped to 20,480 tpy SO₂ in 2015.⁴ Based on a comparison of 2015 and 2016 Quarters 1 – 3 data submitted to the Air Markets Program Division

¹ *Review of EPA-s Cost Analysis for Arkansas Regional Haze Proposed Federal Implementation Plan (2015)*. Prepared by Sargent & Lundy for Entergy Arkansas, Inc., Docket No. EPA-R06-OAR-2015-0189.

<<https://eis.epa.gov/eis-system-web>>

⁴ Air Markets Program Data: Air Markets Program Data: Annual SO₂ Data for Entergy White Bluff for 2015
<<https://ampd.epa.gov/ampd/>>

of EPA, 2016 SO₂ emissions from Entergy White Bluff are on track to be even lower than 2015 SO₂ emissions. Because Entergy White Bluff's actual emissions are much lower than permitted and emissions from Entergy White Bluff are expected to continue to remain low due to economic dispatch throughout the remainder of the current Regional Haze planning period, it does not make sense to require installation of costly controls during the 2008 – 2018 planning period based on the assumption that Entergy will run at a greater capacity than is economically realistic.

EPA's BART determination overstates the cost-effectiveness of installing scrubbers at Entergy White Bluff. EPA underestimates certain costs, makes unreasonable assumptions with respect to the amortization period for the scrubbers, and makes errors in calculating baseline emissions and achievable emission reductions.⁵ EPA estimates the cost-effectiveness of scrubbers at Entergy White Bluff units 1 and 2 to be \$2,227/ ton and \$2,101, respectively. By contrast, total cost-effectiveness estimated by S & L ranges from \$6,097 – \$8,599, depending on the unit and remaining useful life assumptions.⁶

b. Existing Controls in Use at the Source

Second, the existing emissions in controls in use at the facility include low-sulfur coal and an enforceable emission rate appropriate for such a BART determination would solidify the improvements that these controls have already made during this planning period and ensure their continued operation until the next planning period. The current permitted emission rate for units 1 and 2 at Entergy White Bluff is 1.2 lb SO₂/million British Thermal Units (MMBtu) based on

⁵ *Review of EPA's Cost Analysis for Arkansas Regional Haze Proposed Federal Implementation Plan (2015)*. Prepared by Sargent & Lundy for Entergy Arkansas, Inc. Docket No. EPA-R06-OAR-2015-0189.

⁶ *Id.*

the new source performance standard for fossil-fuel fired steam generators.⁷ Entergy White Bluff is currently using lower sulfur content coal to minimize costs of compliance with the Acid Rain Program. Using low sulfur coal, Entergy White Bluff has been able to achieve monthly average emission rates in the range of 0.46 – 0.69 lb SO₂/MMBtu.⁸ The average monthly emission rate between 2009 and 2015 was 0.56 lb SO₂/MMBTU for unit 1 and 0.58lb SO₂/MMbtu for unit 2.⁹ Consequently, Entergy White Bluff has already lowered its visibility impact on potentially impacted federal Class I areas during this planning period beyond what would be expected due to emissions at its permitted emission rate. Setting a BART limit based on 0.6 lb SO₂/MMbtu on a 30-day rolling average would render the use of lower sulfur coal permanent and enforceable ensuring the continuation of reduced sulfur dioxide emissions from Entergy White Bluff and the associated visibility improvements at federal Class I areas.

c. Remaining Useful Life

S & L asserts that EPA arbitrarily assumed a longer remaining useful life and lower costs associated with balance of plant costs, owner's cost, escalation, and operating costs. EPA used the estimated life of the scrubber (30 years) for amortization rather than the remaining useful life of the Entergy White Bluff units. This method of amortization is particularly misleading given EPA's typical modeling assumptions use a 40-year book life for coal-fired power plants and a 15 year schedule for financing environmental retrofits. Entergy White Bluff unit 1 began operation in 1980 and unit 2 began operation in 1981. Units 1 and 2 will reach their 40th year in 2020 and 2021, respectively; therefore, an assumption of a 30-year amortization period starting in 2021

⁷ 40 CFR 60.42b(b)

⁸ Air Markets Program Data: Monthly Heat Input and SO₂ Data for Entergy White Bluff for 2009 - 2015
<<https://ampd.epa.gov/ampd/>>

⁹ Id.

does not reasonably take into account remaining useful life of the units. Coal-fired power plants may continue to operate beyond the 40-year book life assumption; but, it is unlikely that these units would operate 30 additional years beyond their book life.

d. Visibility Improvement

Most importantly, the visibility benefits from a low-sulfur coal BART determination would actually occur during this planning period. Requiring compliance with an emission limit appropriate to White Bluff's use of low-sulfur coal would have benefit of being feasible to implement in matter weeks as opposed to years. In addition, this consolidates the visibility improvement that has allowed Arkansas to exceed the FIP's reasonable progress goals for this planning period. In contrast, EPA the installation of dry scrubbers at White Bluff is not feasibility before the end of this planning period in 2018.

1.0 INTRODUCTION

The purpose of this document is to provide guidance to States in setting reasonable progress goals (RPGs) as part of their regional haze state implementation plans (SIPs) and in deciding those measures necessary to meet these goals. We emphasize that this document is merely guidance and that States or the Environmental Protection Agency (EPA) may elect to follow or deviate from this guidance, as appropriate. The ultimate determination of whether a given SIP submission by a State meets the statutory requirements of sections 169A and 169B of the Clean Air Act (CAA) and the regional haze regulations at 40 CFR 51.300 - 309 will be accomplished through notice and comment rulemaking in which the facts and circumstances of each State submission will be evaluated by EPA.

Under the Tribal Authority Rule, 40 CFR part 49, Tribes have the authority to seek “treatment as a State” for purposes of administering certain CAA programs, including the regional haze program. Whether Tribes seek this authority or not, EPA encourages Tribes to participate in the regional planning efforts to address visibility and to consult with neighboring States as they develop their regional haze SIPs. We hope that this guidance will provide Tribes with an understanding of the process for establishing RPGs that will assist them in the consultation process.

1.1 Legislative and Regulatory History

The CAA was amended in August 1977, and a new section 169A was added for the protection of visibility in mandatory class I Federal areas (Class I areas) of great scenic importance. In section 169A(a)(1), Congress established the national goal for visibility protection:

Congress hereby declares as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution.

Section 169A(a)(4), in part, requires EPA to “promulgate regulations to assure reasonable progress toward meeting the national goal.” The CAA also requires States to submit SIPs containing such emission limits, schedules of compliance, and other measures as may be necessary to make reasonable progress toward meeting the goal.¹

¹ CAA §169A(b)(2).

Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program

In the CAA Amendments of 1990, Congress added section 169B to strengthen and reaffirm the national goal. Section 169B(e) calls for EPA to “carry out the Administrator’s regulatory responsibilities under [section 169A], including criteria for measuring ‘reasonable progress’ toward the national goal.”

In response to these mandates, EPA promulgated the regional haze rule (RHR) on July 1, 1999.² Under section 51.308(d)(1) of this rule, States must “establish goals (expressed in deciviews) that provide for reasonable progress towards achieving natural visibility conditions” for each Class I area within a State. These RPGs must provide for an improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period.³

The RHR also requires States to submit a long-term strategy that includes such measures as are necessary to achieve the RPG for each Class I area.⁴ The regulations require States to consider major and minor stationary sources, mobile sources, and area sources in developing their long-term strategies. In addition, States must submit a SIP that contains either emission limitations representing best available retrofit technology (BART) for certain sources put into operation between 1962 and 1977 *or* alternative measures that provide for greater reasonable progress than BART.⁵ The BART requirements were addressed in a rule revising certain provisions of the regulations in section 51.308(e) and promulgating the BART Guidelines.⁶

1.2 Meaning of the Term “Reasonable Progress Goal”

States must establish RPGs, measured in deciviews (dv), for each Class I area for the purpose of improving visibility on the haziest days and ensuring no degradation in visibility on the clearest days over the period of each implementation plan.⁷ RPGs are interim goals that represent incremental visibility improvement over time toward the goal of natural background conditions and are developed in consultation with other affected States and Federal Land

⁷ 40 CFR 51.308(d)(1).

Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program

Managers (FLM).⁸

In determining what would constitute reasonable progress, section 169A(g) of the CAA requires States to consider the following four factors:

- The costs of compliance;
- The time necessary for compliance;
- The energy and non-air quality environmental impacts of compliance; and
- The remaining useful life of existing sources that contribute to visibility impairment.⁹

States must demonstrate in their SIPs how these factors are taken into consideration in selecting the RPG for each Class I area in the State.

The discussion of the statutory factors in this guidance is largely aimed at helping States apply these factors in considering measures for point sources. States may find that the factors can be applied to sources other than point sources; the meaning of the factors, however, should not be unduly strained in order to fit non-point sources. In other words, if common sense dictates that a particular statutory factor cannot be applied to a particular source category, then the State's analysis may reflect that fact, and emissions reductions from such sources may still be included in the SIP.

As noted above, the RHR establishes an additional analytical requirement for States in the process of establishing the RPG. This analytical requirement requires States to determine the rate of improvement in visibility needed to reach natural conditions by 2064, and to set each RPG taking this "glidepath" into account.¹⁰ (The process for determining the glidepath is discussed later in this document.) EPA adopted this approach, in part, to ensure that States use a common analytical framework that accounts for the regional differences affecting visibility and, in part, to ensure an informed and equitable decision making process. The glidepath is not a presumptive target, and States may establish a RPG that provides for greater, lesser, or equivalent visibility improvement as that described by the glidepath.

⁸ 40 CFR 51.308(d)(1)(iv) and 51.308(i).

⁹ CAA §169A(g)(1); 40 CFR 51.308(d)(1)(i)(A).

¹⁰ 40 CFR 51.308(d)(1)(i)(B).

In deciding what amount of emissions reduction is appropriate in setting the RPG, you should take into account the fact that the long-term goal of no manmade impairment encompasses several planning periods. It is reasonable for you to defer reductions to later planning periods in order to maintain a consistent glidepath toward the long-term goal.

1.3 Relationship of Reasonable Progress to BART and the Long-Term Strategy

The RPGs, the long-term strategy, and BART (or alternative measures in lieu of BART) are the three main elements of the regional haze SIPs that States are required to submit by December 17, 2007. The long-term strategy and BART emissions limitations or other alternative measures, including cap-and-trade programs or other economic incentive approaches, are inherently related to the RPG. The long-term strategy is the compilation of “enforceable emissions limitations, compliance schedules, and other measures as necessary to achieve the [RPGs],”¹¹ and is the means through which the State ensures that its RPG will be met. BART emissions limits (or alternative measures in lieu of BART, such as the Clean Air Interstate Rule (CAIR)) are one set of measures that must be included in the SIP to ensure that an area makes reasonable progress toward the national goal, and the visibility improvement resulting from BART (or a BART alternative) is included in the development of the RPG.

¹¹ 40 CFR 51.308(d)(3),

2.0 OVERVIEW OF THE PROCESS FOR DEVELOPING THE RPG

Development of the RPG for each Class I area should be a collaborative process among State, local, and Tribal authorities, Regional Planning Organizations (RPOs), and FLMs. Steps for developing RPGs will be briefly outlined in this section of the guidance, along with references to other guidance and rules where additional detail can be found. The remaining sections of this guidance expand on particular aspects of these steps. In addition, as this is guidance for States in developing RPGs, the use of “you” through the rest of the document refers to States.

2.1 Establish Baseline and Natural Visibility Conditions

To track progress toward the national goal, the RHR, among other things, requires you to establish the “baseline conditions” representing visibility for the best and worst days at the time the regional haze program is established for each Class I area. Once established, the baseline represents the starting point from which reasonable progress will be measured. The RHR also requires you to estimate “natural conditions” for each Class I area that represents the visibility conditions that would exist in the absence of man-made impairment.

As explained in the RHR, the baseline for each Class I area is the average visibility (in dv) for the 20 percent most impaired days, or “worst days”, and for the 20 percent least impaired days, or “best days,” for the years 2000 through 2004.¹² Using available monitoring data for the 2000 to 2004 time period, you are required to calculate the baseline by averaging the annual values (in dv) for the 20 percent worst days in each year (yr) to produce a single value (in dv) that represents the baseline conditions for the worst days. You should follow the same approach for determining the value that represents the baseline conditions for the best days. Natural conditions at each Class I area are also expressed by reference to the level of visibility (in dv) for the 20 percent most impaired and least impaired days.¹³

¹² 64 FR at 35730.

¹³ For more detail on determining baseline and natural conditions, you can review the preamble and regulations in the RHR, 64 FR at 35728 – 35730, 40 CFR 51.308(d)(2), EPA’s *Guidance for Tracking Progress Under the Regional Haze Rule*, EPA-454/B-03-004 (September 2003) available at www.epa.gov/ttn/oarpg/t1/memoranda/rh_tpurhr_gd.pdf, and EPA’s *Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule*, EPA-454/B-03-005 (September 2003) available at www.epa.gov/ttn/oarpg/t1/memoranda/rh_envcurhr_gd.pdf.

2.2 Determine the Glidepath, or Uniform Rate of Progress

By comparing baseline conditions with natural conditions, you can determine the uniform rate of visibility improvement, or progress, needed to reach natural conditions by 2064 for each Class I area. Figure 1, below, illustrates the basic steps in the process for calculating the uniform rate of progress toward natural conditions for the first planning period at a hypothetical Class I area.

Figure 1

Figure 1 Example of a Uniform Rate of Progress

- Compare baseline conditions to natural conditions. The difference between these two represents the amount of progress needed to reach natural visibility conditions. In this example, the State has determined that the baseline for the 20 percent worst days for the Class I area is 29 dv and estimated that natural background is 11 dv, a difference of 18 dv.
- Calculate the annual average visibility improvement needed to reach natural conditions by 2064 by dividing the total amount of improvement needed by 60 years (the period between 2004 and 2064). In this example, this value is 0.3 dv/yr.

- Multiply the annual average visibility improvement needed by the number of years in the first planning period (the period from 2004 until 2018). In this example, this value is 4.2 dv. This is the uniform rate of progress that would be needed during the first planning period to attain natural visibility conditions by 2064.

If you were to achieve this steady improvement in visibility over the next 60 years, you would reach the national goal by 2064.

2.3 Identify and Analyze the Measures Aimed at Achieving the Uniform Rate of Progress.

The next step in setting an RPG is to identify and analyze the measures aimed at achieving the uniform rate of progress and to determine whether these measures are reasonable based on the statutory factors identified in Section 1.2 above. To meet this requirement, we suggest the following approach which ensures that States consider all reasonable measures in developing their regional haze SIPs:

- Identify the key pollutants and sources and/or source categories that are contributing to visibility impairment at each Class I area. The sources of impairment for the most impaired and least impaired days may differ. Section 3 discusses this process.
- Identify the control measures and associated emission reductions that are expected to result from compliance with existing rules *and* other available measures for the sources and source categories that contribute significantly to visibility impairment. This is covered in more detail in Section 4.
- Determine what additional control measures would be reasonable based on the statutory factors and other relevant factors for the sources and/or source categories you have identified.
- Estimate through the use of air quality models the improvement in visibility that would result from implementation of the control measures you have found to be reasonable and compare this to the uniform rate of progress.

Another possible approach that some States and RPOs are using is to “back out” the measures necessary to achieve the uniform rate of progress. In this process, States are using dispersion modeling to estimate the visibility impacts of a specific percentage reduction in visibility impairing pollutants. The resulting visibility conditions are then compared to the uniform rate of progress. Using this process, States will be able to identify a percentage

reduction in visibility impairing pollutants that would provide progress at or beyond the uniform rate of progress. In a separate step, States would consider the statutory factors along with other relevant factors to select appropriate measures to achieve the identified reduction in emissions. States can thus identify the measures that would be needed to achieve the uniform rate of progress at a Class I area and determine whether such measures are reasonable.

2.4 Establish a RPG

In developing a RPG, you must consult with other States with emissions sources that may reasonably be anticipated to cause or contribute to visibility impairment at Class I areas in your State.¹⁴ The regulations anticipate that States may not always agree on what measures would be reasonable or on the appropriateness of a RPG. We encourage States to work together early and often to resolve such issues. In addition, the FLMs may provide insight and assistance to States in identifying regional approaches to address the RPG.

The improvement in visibility resulting from implementation of the measures you have found to be reasonable, considering the uniform rate of progress, is the amount of progress that represents your RPG. The regional haze rule requires you to clearly support your RPG determination in your SIP submission based on the statutory factors.¹⁵

¹⁴ 40 CFR 51.308(d)(1)(iv).

¹⁵ 40 CFR 51.308(d)(1)(i)(A).

3.0 IDENTIFYING KEY POLLUTANTS AND SOURCE CATEGORIES FOR THE FIRST PLANNING PERIOD

This process begins with the identification of key pollutants and source categories that contribute to visibility impairment at the Class I area. Such analysis has been the subject of considerable study over the past decade, including studies by the Grand Canyon Visibility Transport Commission and ongoing work by RPOs. For the purpose of this document, it is assumed that analyses identifying the key pollutants contributing to visibility impairment have been conducted for each Class I area.

3.1 Identification of Source Categories From Which These Pollutants and Their Precursors Are Emitted

Once the key pollutants contributing to visibility impairment at each Class I area have been identified, the sources or source categories responsible for emitting these pollutants or pollutant precursors can also be determined. There are several tools and techniques being employed by the RPOs to do so, including analysis of emission inventories, source apportionment, trajectory analysis, and atmospheric modeling. Technical guidance on these tools and techniques is beyond the scope of this document. Instead, this document focuses on policy considerations relevant to the identification of which source categories should be considered as part of the regional haze SIP development process.

When identifying the sources or source categories responsible for regional haze, you should consider the relationship between the RPG and the requirements for long-term strategies. The regulations require States to consider major and minor stationary sources, as well as mobile and area sources, in developing long-term strategies.¹⁶ At a minimum, the regulations require you to consider several factors when developing a long-term strategy, including the following:

- Emissions reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment and those taken to attain the fine particulate matter (PM_{2.5}) national ambient air quality standards (NAAQS).
- Measures to mitigate the impact of construction activities.
- Smoke management techniques for agricultural and forestry management purposes.

¹⁶ 40 CFR 51.308(d)(3)(iv).

Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program

- Anticipated visibility effects from changes in point, area, and mobile source emissions.¹⁷

As illustrated by these factors, States should consider a broad array of sources and activities when deciding which sources or source categories contribute significantly to visibility impairment.

¹⁷ 40 CFR 51.308(d)(3)(v).

4.0 IDENTIFY CONTROL MEASURES FOR CONTRIBUTING SOURCE CATEGORIES FOR THE FIRST PLANNING PERIOD

There are numerous possible conceptual approaches that you can use to identify control measures for the long-term strategy and the related RPG. We suggest beginning by concentrating on possible emissions reductions of several pollutant species from a few selected source sectors, focusing on those source categories that may have the greatest impact on visibility at Class I areas, considering cost and the other factors discussed further in Section 5.0.

4.1 Consideration of Emissions Reductions from State, Federal, and Local Control Measures

One important factor to keep in mind when establishing a RPG is that you cannot adopt a RPG that represents less visibility improvement than is expected to result from the implementation of other CAA requirements.¹⁸ You must therefore determine the amount of emission reductions that can be expected from identified sources or source categories as a result of requirements at the local, State, and federal levels during the planning period of the SIP and the resulting improvements in visibility at Class I areas. Given the significant emissions reductions that we anticipate to result from BART, the CAIR, and the implementation of other CAA programs, including the ozone and PM_{2.5} NAAQS, for many States this will be an important step in determining your RPG, and it may be all that is necessary to achieve reasonable progress in the first planning period for some States.

The first step in this process is to identify the baseline emissions inventory year on which your strategies are based. For the first RHR SIP, we anticipate that States will use 2002 as the baseline year for emission inventories.¹⁹ If you do use 2002, you may take credit in your long-term strategy for emission reductions achieved after 2002. This includes emission reductions from measures implemented to attain the ozone and PM_{2.5} NAAQS,²⁰ and Federal programs, such as the national mobile source program and federal standards for hazardous air pollutants (air toxics).

¹⁸ 40 CFR 51.308(d)(1)(vi).

¹⁹ 40 CFR 51.308(d)(3)(iii) provides that the baseline emission inventory year is presumed to be the most recent year of the consolidated emissions inventory for the SIP. A memorandum from OAQPS, entitled *2002 Base Year Emission Inventory SIP Planning: 8-hr Ozone, PM 2.5, and Regional Haze Programs* (November 18, 2002) (“2002 EI Memo”), identifies 2002 as the anticipated baseline emission inventory year for regional haze. See www.epa.gov/ttn/oarpg/t1/memoranda/2002bye_gm.pdf

²⁰ 2002 EI Memo at 3-4.

4.2 Identification of Additional Emissions Control Strategies for the Source Categories Identified

After determining the amount of emissions reductions of visibility impairing pollutants that may be expected from implementation of other CAA programs, you will be ready to identify any additional measures that are reasonable. The RHR gives States wide latitude to determine additional control requirements, and there are many ways to approach identifying additional reasonable measures; however, you must at a minimum, consider the four statutory factors. Based on the contribution from certain source categories and the magnitude of their emissions you may determine that little additional analysis is required to determine further controls are not warranted for that category. As discussed further in section 5, you have considerable flexibility in how you take these factors into consideration. In addition to source-specific controls, emissions cap-and-trade programs may be considered. Sources of information on control techniques for specific source categories include the RACT/BACT/LAER Clearinghouse and EPA's AIRControlNet database.²¹

One approach that you could take to streamline what could be an extremely complex task would be to first identify alternative control scenarios with different levels of stringency. Each control scenario would assume application of specific control levels or measures to the sources or source categories you have identified as the significant sources of visibility impairment. As indicated previously in section 4.1, the starting point for this assessment is the visibility improvement achieved as a result of BART, the CAIR, and the implementation of other CAA programs, including other measures for attainment of the ozone and PM_{2.5} NAAQS. You would then consider whether any additional control scenarios are reasonable based on your consideration of the statutory factors and any other factors you have determined are relevant.

Another approach you could take, consistent with the "back out" approach discussed in section 2.3, would involve identifying the set of emissions control measures that achieves the target percentage reductions in visibility-impairing pollutants associated with progress at or beyond the uniform rate of progress. The selection of control measures to include in this set would be guided by your consideration of the statutory factors and any other factors you have determined are relevant.

Note that for some sources determined to be subject to BART, the State will already have completed a BART analysis. Since the BART analysis is based, in part, on an assessment of many of the same factors that must be addressed in establishing the RPG, it is reasonable to

²¹ Information on AirControlNet can be found at www.epa.gov/ttn/ecas/econtool.html. The RACT/BACT/LAER Clearinghouse is located at <http://cfpub.epa.gov/rblc/htm/bl02.cfm>.

Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program

conclude that any control requirements imposed in the BART determination also satisfy the RPG-related requirements for source review in the first RPG planning period. Hence, you may conclude that no additional emissions controls are necessary for these sources in the first planning period.

5.0 APPLYING STATUTORY FACTORS TO POTENTIALLY AFFECTED STATIONARY SOURCES

In determining reasonable progress, CAA §169A(g)(1) requires States to take into consideration a number of factors. However, you have flexibility in how to take into consideration these statutory factors and any other factors that you have determined to be relevant. For example, the factors could be used to select which sources or activities should or should not be regulated, or they could be used to determine the level or stringency of control, if any, for selected sources or activities, or some combination of both. The factors may be considered both individually and/or in combination. As noted in section 4.1, given the significant emissions reductions that we anticipate to result from BART, the CAIR, and the implementation of other CAA programs, these reductions may be all that is necessary to achieve reasonable progress in the first planning period for some States. Also, as noted in section 4.2, it is not necessary for you to reassess the reasonable progress factors for sources subject to BART for which you have already completed a BART analysis.

5.1 Reasonable Progress Statutory Factor (a): Costs of Compliance

The first factor to take into consideration is the “costs of compliance.” In this context we believe that the cost of compliance factor can be interpreted to encompass the cost of compliance for individual sources or source categories, and more broadly the implication of compliance costs to the health and vitality of industries within a state. For additional guidance on applying the cost of compliance factor to stationary sources, you may wish to consult the BART guidelines, referenced above.

To assess compliance costs for individual sources or source categories potentially subject to emission limitations, we suggest that you use established control cost analysis techniques. For stationary sources, generally this involves the following:²²

- a) Identify the emissions units to be controlled;
- b) Identify the design parameters for emissions controls; and
- c) Develop cost estimates based upon those design parameters.

²² As noted above, application of the cost factor to non-point sources is beyond the scope of this guidance. This is also true for mobile sources.

You should evaluate both average and incremental costs. To maintain and improve consistency wherever possible, cost estimates should be based on EPA's *Air Pollution Control Cost Manual*.²³

In considering the cost of compliance factor, you should keep in mind that different pollutants differently impact visibility impairment. For example, on a ton basis, sulfur dioxide-related particles have a greater impact on visibility impairment than crustal material. Therefore, in assessing additional emissions reduction strategies for source categories or individual, large scale sources, simple cost effectiveness estimates based on a dollar-per-ton calculation may not be as meaningful as a dollar-per-deciview calculation, especially if the strategies reduce different groups of pollutants.

5.2 Reasonable Progress Statutory Factor (b): Time Necessary for Compliance

The second factor is the “time necessary for compliance.” It may be appropriate for you to use this factor to adjust the RPG to reflect the degree of improvement in visibility achievable within the period of the first SIP if the time needed for full implementation of a control measure (or measures) will extend beyond 2018. For example, if you anticipate that constraints on the availability of construction labor will preclude the installation of controls at all sources of a particular category by 2018, the visibility improvement anticipated from installation of controls at the percentage of sources that *could* be controlled within the strategy period should be considered in setting the RPG and in establishing the SIP requirements to meet the RPG.

5.3 Reasonable Progress Statutory Factor (c): Energy and Non-Air Impacts

The third factor is “energy and non-air environmental impacts.” In assessing energy impacts, you may want to consider whether the energy requirements associated with a control technology result in energy penalties. For example, controls on diesel engines may decrease the engine's fuel efficiency, leading to an increase in diesel fuel consumption. Or, a particular control may require a fuel unavailable in the area. To the extent that these considerations are quantifiable they should be included in the engineering analyses supporting compliance cost estimates.

Some examples of non-air environmental impacts that you may wish to consider, are the effects of the waste stream that may be generated by a particular control technology, and/or other

²³ Any additional information used for the cost calculations, including any information supplied by vendors that affects your assumptions regarding purchased equipment costs, equipment life, replacement of major components, and any other element of the calculation that differs from the *Control Cost Manual*, should be documented. EPA's *Control Cost Manual* is located at: www.epa.gov/ttn/catc1/products.html#cccinfo.

resource consumption rates such as water, water supply, and waste water disposal. To the extent that these considerations are quantifiable, they should also be included in the analyses supporting compliance cost estimates.

For additional guidance on applying this factor to stationary sources, you may wish to consult the BART Guidelines, referenced above.

5.4 Reasonable Progress Statutory Factor (d): The Remaining Useful Life of the Source

The fourth statutory factor is “the remaining useful life of any existing source subject to [reasonable progress] requirements.” This factor is generally best treated as one element of the overall cost analysis. The “remaining useful life” of a source, if it represents a relatively short time period, may affect the annualized costs of retrofit controls. For example, the methods for calculating annualized costs in EPA’s *Air Pollution Control Cost Manual* require the use of a specified time period for amortization that varies based upon the type of control. If the remaining useful life of the source will clearly exceed this time period, the remaining useful life factor has essentially no effect on control costs and on the reasonable progress determination process. Where the remaining useful life of the source is less than the time period for amortizing the costs of the retrofit control, you may wish to use this shorter time period in your cost calculations.

For additional guidance on applying this factor to stationary sources, you may wish to consult the BART Guidelines, referenced above.

Sargent & Lundy Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

Introduction

The Arkansas Department of Environmental Quality (ADEQ) is in the process of revising portions of the Arkansas Regional Haze State Implementation Plan (SIP) to replace the Federal Implementation Plan (FIP) published by the U.S. Environmental Protection Agency (EPA) on September 27, 2016.¹ On October 31, 2017, ADEQ proposed a SIP revision addressing, among other elements of the SIP, sulfur dioxide (SO₂) control requirements for Entergy's White Bluff Generating Station Units 1 and 2.

To support the SIP development process, and at ADEQ's request, Entergy submitted an updated Best Available Retrofit Technology (BART) analysis for the control of SO₂ emissions from White Bluff Units 1 & 2. *White Bluff Steam Electric Station, Updated BART Five-Factor Analysis for SO₂ for Units 1 and 2* (Aug. 18, 2017) ("Revised BART Analysis"). The Revised BART Analysis included updated SO₂ control technology cost estimates for three control scenarios, and a revised cost-effectiveness analysis to reflect the shortened useful remaining life proposed by Entergy for the White Bluff units (firing coal). Available SO₂ retrofit control technology options evaluated by ADEQ for White Bluff Units 1 and 2 included: lower sulfur coal; dry sorbent injection (DSI) at two control levels; and dry flue gas desulfurization (DFGD). Control system costs for the BART determination were prepared for Entergy by Sargent & Lundy LLC (S&L). Detailed cost estimating basis reports were prepared for each technology and included as attachments to Entergy's Revised BART Analysis.²

Based on the Revised BART Analysis, ADEQ proposed low sulfur coal and an SO₂ emission limit of 0.60 lb/MMBtu (30-day rolling average) as BART for White Bluff Units 1 & 2. ADEQ concluded that add-on SO₂ control technologies were not cost-effective given the shortened remaining useful coal-fired life of

¹ On September 27, 2016, at 81 Fed. Reg. 66332, the U.S. Environmental Protection Agency (EPA) published a final Federal Implementation Plan (FIP) addressing the requirements of the Regional Haze Rule and interstate visibility transport for the portions of Arkansas' Regional Haze State Implementation Plan (SIP) that EPA disapproved in a final rule published in the Federal Register on March 12, 2012. In the March 2012 action, EPA partially approved and partially disapproved the State's plan to implement the regional haze program for the first planning period. 77 Fed. Reg. 14604 (Mar. 12, 2012).

Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

the White Bluff units. ADEQ relied on Entergy's Revised BART Analysis and updated cost-effectiveness analysis which showed that DFGD had an average cost effectiveness of more than \$5,400/ton and that the DSI control options had an average cost effectiveness exceeding \$6,000/ton. (ADEQ NODA, Table 4-4, pg. 4-5).

On February 2, 2018 the Conservation Organizations submitted comments on the proposed SIP revisions. *Comments of Sierra Club, National Parks Conservation Association and Earthjustice on Revisions to the Arkansas State Implementation Plan: Regional Haze SIP Revision for the 2008-2018 Planning Period* (Feb. 2, 2018) ("Conservation Organizations comments"). Conservation Organizations comments included a Technical Support Document dated February 1, 2018 prepared by Ms. Victoria Stamper, addressing Entergy's revised BART analysis and ADEQ's proposed SO₂ BART determination for White Bluff Units 1 & 2 (the "Stamper Report"). In general, the Stamper Report asserts that: (1) Entergy's revised cost-effectiveness analyses for White Bluff are flawed and do not demonstrate that the costs of add-on SO₂ controls at White Bluff Units 1 & 2 are not reasonable; (2) Entergy's cost-effectiveness analyses of DSI at 50% control and Enhanced DSI are based on unrealistic design parameters that tend to overestimate control system costs; (3) control system design parameters, annual emission reductions, and annual O&M costs were calculated using an incorrect baseline period; and (4) control system costs estimates provided by Entergy were not developed in accordance with EPA's *Control Cost Manual*.³

This report provides a response to comments submitted by the Conservation Organizations through the Stamper Report. Information provided herein supports the conclusion that ADEQ reasonably relied on costs provided by Entergy in its August 18, 2017 Revised BART Analysis to establish SO₂ BART controls for White Bluff Units 1 & 2.

³ Stamper Report, pgs. 6-18.

A. Conservation Organization Comment: Entergy's cost-effectiveness analysis of DSI at 50% control is based on unrealistic design parameters that tend to overestimate control system costs⁴

Ms. Stamper provides three general arguments to support her assertion that Entergy's cost-effectiveness analysis of DSI at 50% control is based on unrealistic design parameters that would tend to overestimate control costs. First, she argues that S&L used an incorrect baseline period to establish the control system design parameters, estimate annual O&M costs, and estimate annual emission reductions. Second, she argues that S&L used an incorrect inlet SO₂ loading rate to size and cost the DSI control equipment, and to calculate annual O&M costs and annual emission reductions. Third, she contends that these "unrealistic" design considerations resulted in S&L including costs for an unnecessary ESP upgrade. A response to each of the assertions is provided below.

1.0 Emissions from White Bluff Units 1 and 2 during the 2009-2013 timeframe provide a realistic depiction of anticipated annual emissions for the units; thus, the 2009-2013 timeframe is an appropriate baseline period for the units' BART cost-effectiveness evaluation

S&L established control system design parameters, calculated annual O&M costs, and calculated annual SO₂ emission reductions based on actual emissions from White Bluff Units 1 & 2 during the 2009-2013 baseline period. Annual emissions from White Bluff Units 1 & 2 during the 2009-2013 timeframe averaged 15,939 tons per year (tpy) and 16,034 tpy, respectively. Ms. Stamper asserts that 2001-2003 was a more appropriate baseline period.⁵ During the 2001-2003 baseline period annual emissions from White Bluff Units 1 & 2 were higher, averaging 19,716 and 17,007 tpy, respectively

Ms. Stamper contends that the more recent 2009-2013 baseline reflects a lower sulfur content coal than the coal used at White Bluff during the 2001-2003 timeframe, and that using the 2001-2003 baseline period "is most consistent with the baseline period that EPA has stated is to be used for

⁴ Stamper Report, pg. 9.

Prepared by Victoria R. Stamper, February 1, 2018

baseline visibility conditions in EPA's regional haze rules. (emphasis added)"⁶ She further asserts that "EPA's 'consistency' rationale requires that the baseline for the BART cost analysis cover a similar period."⁷

The consistency rationale referenced by Ms. Stamper refers to establishing baseline visibility conditions that states can use to determine their reasonable progress glide path and demonstrate reduced visibility impacts.⁸ However, the consistency rationale does not extend to using the same period to evaluate BART controls. In fact, using 2001-2003 emissions data to establish baseline emissions from White Bluff Units 1 & 2 is inconsistent with the BART Guidelines at 40 CFR Part 51 Appendix Y.

EPA's BART Guidelines define annual emissions reductions as "the difference between baseline annual emissions and the estimate of emissions after controls."⁹ The BART Guidelines state that baseline emissions from existing sources "should represent a realistic depiction of anticipated annual emissions for the source."¹⁰ In the absence of future operating parameters that differ significantly from the baseline period, facilities should "calculate baseline emissions based upon continuation of past practice."¹¹

Entergy has no plans to utilize coals with significantly different characteristics (e.g., heating value and sulfur content) than the coals used at White Bluff for the past several years, including the 2009-2013 timeframe. Thus, emissions from 2009-2013 provide a realistic depiction of anticipated annual emissions from White Bluff Units 1 & 2, and 2009-2013 represents an appropriate baseline period for

the White Bluff BART evaluation. Further, this is the time period that was used by EPA in its development of baseline emissions for the FIP.¹²

¹² See 81 Fed. Reg. at 66331

2.0 S&L's August 2017 Cost Estimate for DSI at 50% Control was based on Realistic Control System Design Parameters and Sound Engineering Judgment and Assumptions

Ms. Stamper asserts that S&L's cost estimate for DSI at the 50% control option was based on unrealistic control system design parameters, including: (1) an inlet SO₂ rate of 0.76 lb/MMBtu; (2) a design target emission rate of 0.35 lb/MMBtu; and (3) the need to rebuild the existing ESP control systems.¹³ Control system design parameters and assumptions used by S&L to develop the cost estimates are addressed below.

2.1 Design parameters used by S&L to develop DSI control system costs were based on facility-specific operating information and sound engineering judgment to properly size and cost control system components

S&L used an SO₂ design inlet rate of 0.76 lb/MMBtu to size and cost major components of the DSI control system.¹⁴ The 0.76 lb/MMBtu emission rate represents the highest 5% of SO₂ emissions during the 2009-2013 baseline period.¹⁵ Because the cost-effectiveness of an air pollution control system is calculated as an annualized cost effectiveness (i.e., the annual cost of controls divided by the annual tons of pollutant removed), Ms. Stamper contends that “the design and cost of controls should be based on the average annual reductions in SO₂ emission rate, not the highest 5% of SO₂ emissions over the baseline period.”¹⁶ She concludes that “the capital and operating costs for the DSI system evaluated by Entergy are inflated based on the cost to reduce SO₂ by 50% from [an] uncommonly high SO₂ rate for the White Bluff Units.”¹⁷

Ms. Stamper is confusing the cost-effectiveness calculation with the approach engineers use to design, size, and cost air pollution control systems. Air pollution control systems are not

Prepared by Victoria R. Stamper, February 1, 2018

designed or sized based on average design conditions, in this case the annual average SO₂ loading to the control system. To do so would result in control system components that are undersized, and a system that would not be able to meet target emission rates when inlet loading exceeds the average.

DSI control system components, including reagent storage, milling, conveyance, and reagent injection systems, as well as upgrades to the ESP ash handling systems, must be sized based on a reasonable estimate of the maximum SO₂ inlet rate to the control system. Sizing the major system components based on an average SO₂ inlet rate would result in inadequately sized reagent handling and ash handling systems. Sizing the system based on a design inlet SO₂ rate of 0.76 lb/MMBtu, the highest 5% of SO₂ emissions during the 2009-2013 baseline period, is an appropriate methodology to establish the design inlet SO₂ rate and size the DSI control system components.

2.2 S&L calculated annual emission reductions and annual O&M control technology costs based on facility-specific operating parameters

Ms. Stamper contends that Entergy understated the annual tons per year reduced with the DSI control system by basing the achievable emission limit (i.e., the design target emission rate of 0.35 lb/MMBtu) on less than a 50% reduction in annual average SO₂ emissions.¹⁸ However, in order to achieve compliance under all normal operating conditions, the design target emission rate must be based on a reasonable estimate of the highest SO₂ loading rate to the control system, not the average inlet rate. The design target emission rate of 0.35 lb/MMBtu (30-day average) was based on the highest 30-day average emission rate achieved during the baseline period, and represents an appropriate design target for the control technology evaluation.

¹⁸ *Id.*

Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

Ms. Stamper also contends that “operating costs for the DSI system evaluated by Entergy are inflated based on the cost to reduce SO₂ by 50% from uncommonly high SO₂ rate for the White Bluff units”¹⁹ However, as described in S&L's Report SL-014000, annual O&M costs were calculated based on 50% SO₂ removal from an uncontrolled SO₂ rate of 0.57 lb/MMBtu, the annual average SO₂ emission rate during the 2009-2013 baseline period.

In summary, S&L sized the DSI control system components based on an inlet SO₂ loading rate of 0.76 lb/MMBtu, the highest 5% of SO₂ emission rates during the 2009-2013 baseline period. Capital costs were generated based on control system components sized to treat all reasonably anticipated SO₂ inlet loading rates. Annual O&M costs were calculated assuming 50% SO₂ removal from an uncontrolled SO₂ rate of 0.57 lb/MMBtu, the annual average SO₂ emission rate during the baseline period. The approach used by S&L to calculate capital costs and O&M costs was appropriate based on sound engineering principles, and did not inflate the capital costs or operating costs of the control system.

2.3 *Based on the design and operating parameters established for the DSI control system, it is very likely that the White Bluff Unit 1 & 2 ESPs would have to be rebuilt as part of the DSI project; thus, costs for the ESP rebuild should be included in the BART cost evaluation*

Ms. Stamper asserts that “these and other unrealistic design considerations were carried over into an ESP upgrade that Sargent & Lundy stated may not even be needed at the White Bluff units with DSI at 50% controls but yet included the costs in its DSI cost effectiveness analysis.”²⁰ Design parameters identified as being unrealistic included: (1) the design ash loading rate to the ESP of 55,000 lb/hr; (2) the design Trona injection rate of 22,000 lb/hr; and (3) an outlet PM emission rate of 0.015 lb/MMBtu.²¹

¹⁹ *Id.*

²⁰ *Id.*

Sargent & Lundy L.L.C.
 Comments on the Conservation Organization's Technical Support Document
 Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
 State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
 Prepared by Victoria R. Stamper, February 1, 2018

Operating parameters used by S&L to evaluate potential impacts to the ESP and controlled PM emissions were established using the original ESP design information and operating parameters established for the DSI control system. Fly ash loading to the ESP was based on a coal heating value of 8,450 Btu/lb, 6.5% ash, and assuming 80% of the ash being emitted as fly ash²² as shown below:

$$\text{Fly Ash Loading} = \frac{\text{Heat Input (Btu/hr)}}{\text{Heating Value (Btu/lb)}} \times \frac{\text{Coal Ash Content (\%)}}{100\%} \times \frac{\text{Fly Ash Split (\%)}}{100\%}$$

Based on our experience designing particulate matter control systems, the uncontrolled PM emission factor from AP-42 Table 1.4-1, on which Ms. Stamper relied to calculate ash loading to the ESP (i.e., 10A lb. PM/ton of coal fired, where A = ash content), does not accurately reflect particulate loading at the boiler outlet. Accordingly, establishing control system design parameters using the AP-42 emissions factor would result in an undersized control system.

The Trona injection rate was calculated based on the design SO₂ inlet rate of 0.76 lb/MMBtu (discussed in Section 2.1) and a normalized stoichiometric ratio (NSR) of 1.3 to achieve 50% removal, as shown below:

$$\begin{aligned} \text{Trona Injection Rate} = & \frac{\text{Inlet SO}_2 \text{ (lb/hr)}}{\text{SO}_2 \text{ MW (lb/lb-mole)}} \times \frac{2 \text{ Moles Na}}{1 \text{ Mole SO}_2} \times \text{NSR} \times \frac{1 \text{ Mole Trona}}{3 \text{ Moles Na}} \\ & \times \text{Trona MW (lb/lb-mole)} \times \frac{100\%}{\text{Purity (\%)}} \end{aligned}$$

With respect to the outlet PM emission rate of 0.015 lb/MMBtu, Ms. Stamper argues that the White Bluff units are subject to a PM permit limit that is more than 6 times higher than the target PM emission limit, while conceding that “Energy would want to ensure that actual PM emissions

²² The Babcock & Wilcox Company, *Steam: Its Generation and Use; Edition 41*, Chapter 21. “In a dry-bottom unit most of the ash, typically 70 to 80%, is entrained in the flue gas and carried out of the furnace. This portion of the ash is commonly known as *flyash*.”

Sargent & Lundy L.L.C.
Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

do not increase above PSD significance levels and trigger PSD permitting.”²³ (Stack test data provided by Ms. Stamper showed controlled PM emission rates of 0.019 and 0.016 lb/MMBtu for White Bluff Units 1 & 2, respectively. Modeling conducted by S&L estimated controlled PM emissions of approximately 0.0155 lb/MMBtu, consistent with the stack test results. A design target of 0.015 lb/MMBtu, an emission rate slightly below existing actual emissions from the units, is a reasonable design parameter for evaluating control system operations and provides a compliance margin.

Regardless of the target PM emission rate, the New Source Review applicability determination is based on a past-actual to projected-future-actual test. The PSD significance level for filterable PM is 25 tpy.²⁴ ESPs operate at a constant efficiency assuming the operating conditions (such as temperature, ash resistivity, or flue gas velocity) stay the same; therefore, increased particulate loading to the ESP will likely result in an incremental increase in controlled emissions.

Assuming an annual heat input of 55,830,000 MMBtu/yr (the actual average annual heat input to White Bluff Unit 1 during the 2009-2013 baseline period), an increase in the controlled PM emission rate of only 0.0009 lb/MMBtu would result in an emissions increase greater than the PSD significant level (55,830,000 MMBtu/hr x 0.0009 lb/MMBtu ÷ 2000 lb/ton = 25.1 tpy increase for a single unit). Because, as Ms. Stamper concedes, Entergy would want to ensure that actual PM emissions do not increase above PSD significance levels, a design target emission rate of 0.015 lb/MMBtu following installation of the DSI control system is a reasonable design parameter.

As described in detail in S&L's Report SL-014000, S&L used EPA's ESPVI 4.0W Performance Prediction Model to simulate ESP operating scenarios with and without DSI.²⁵ That evaluation

²³ *Id.*

²⁴ 40 CFR 52.21(b)(23)(i).

²⁵ S&L Report SL-014000, pg. 6.

Sargent & Lundy L.L.C.
Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

concluded that, given the high Trona injection rates needed to achieve 50% SO₂ removal, an ESP rebuild will likely be required to ensure PM emission increases stay below the applicable PSD threshold. In addition to modeling the White Bluff ESPs, S&L engaged an equipment vendor experienced with ESP retrofits to evaluate ESP performance and upgrade requirements. The equipment vendor, FuelTech, concluded, based on the design parameters discussed above, that it would be "extremely difficult to achieve the requested 0.015 lb/MMBtu outlet PM emissions, without retrofitting the entire ESPs to BART technology." [FuelTech Report, October 17, 2016, pg. 4].

Based on the significant increase in particulate loading to the ESP with DSI, ESP performance modeling with and without DSI, and input from an ESP equipment vendor, it is very likely that the ESPs would have to be rebuilt as part of a DSI project to ensure that the air pollution control project would not trigger PSD permitting, and costs for the ESP rebuild should be included in the BART cost evaluation. By removing ESP upgrade costs, Ms. Stamper significantly underestimated the capital costs Entergy would incur to implement DSI at 50% control.

B. Conservation Organization Comment: Entergy's cost analysis of "Enhanced DSI" is also based on design parameters that would overestimate costs of controls

Ms. Stamper repeats her DSI at 50% control comments to support her conclusion that Entergy's cost-effectiveness analysis of Enhanced DSI (i.e., DSI designed for 80% SO₂ removal) was based on unrealistic design parameters that would tend to overestimate control costs.²⁶ In general, Ms. Stamper asserts that: (1) S&L used an incorrect baseline period to establish control system design parameters; (2) a design inlet rate of 0.76 lb/MMBtu is unrealistically high; (3) a design target emission rate of 0.15 lb/MMBtu does not reflect 80% control; and (4) the design and cost of controls should be based on the average annual reduction in the SO₂ emission rate, not the highest 5% of SO₂ emissions over the baseline period.²⁷

As discussed in Section 1.0, emissions from 2009-2013 provide a realistic depiction of anticipated annual emissions from White Bluff Units 1 & 2 and this timeframe was used by EPA to develop baselines for the FIP. Therefore, using the 2009-2013 timeframe to establish baseline emissions for the White Bluff BART determination meets the requirements of Section IV.D.4.d of the BART Guidelines. Using emissions from 2001-2003, as suggested by Ms. Stamper, would not provide a realistic depiction of anticipated emissions from the White Bluff units, and would not be consistent with the BART Guidelines.

As discussed in Section 2.1, air pollution control system components, including reagent storage, milling, conveyance, and reagent injection systems, as well as upgrades to the ash handling systems, must be sized based on a reasonable estimate of the maximum SO₂ inlet rate to the control system. Sizing the major system components based on an average SO₂ inlet rate would result in inadequately sized systems. Sizing the system components based on a design inlet SO₂ rate of 0.76 lb/MMBtu, the highest 5% of SO₂ emissions during the baseline period, is an appropriate methodology to size the DSI control system components. Similarly, the design target emission rate (0.15 lb/MMBtu) was established based on 80%

²⁶ Stamper Report, pg. 11.

²⁷ *Id.*

SO₂ control from the highest 30-day emission rate during the baseline period, not 80% removal from the annual average baseline SO₂ emission rate of 0.57 lb/MMBtu.²⁸ As with the 50% DSI control option, annual O&M costs for the Enhanced DSI option were calculated based on 80% SO₂ removal from an uncontrolled SO₂ rate of 0.57 lb/MMBtu, the annual average SO₂ emission rate during the 2009-2013 baseline period.²⁹

In summary, S&L sized the Enhanced DSI control system components based on an inlet SO₂ loading rate of 0.76 lb/MMBtu, the highest 5% of SO₂ emission rate during the 2009-2013 baseline period control system. Capital costs were generated based on control system components sized to treat all reasonably anticipated SO₂ inlet loading rates. Annual O&M costs were calculated assuming 80% SO₂ removal from an uncontrolled SO₂ rate of 0.57 lb/MMBtu, the annual average SO₂ emission rate during the baseline period. The approach used by S&L to calculate capital costs and O&M costs was appropriate based on sound engineering principals, and did not inflate the capital costs or operating costs of the control system.

C. Conservation Organization Comment: ADEQ Must Ensure that the Cost Effectiveness Analyses Relied on for its Revised BART Determinations Are Not Based on Costs that EPA Does Not Allow in BART Cost Effectiveness Analyses

Ms. Stamper asserts that ADEQ must ensure that the cost effectiveness analyses relied on for its revised BART determinations are not based on costs that EPA does not allow in BART cost effectiveness analyses, and suggests that “it is not clear whether the cost effectiveness numbers being relied on by ADEQ comport with the methodology of EPA’s *Control Cost Manual*.”³⁰ She also states that “[i]t appears that Entergy’s cost effectiveness analysis that [ADEQ] is relying on is based on an entirely different ‘all in’ costing methodology, which seek to determine the actual cost to the owner.”³¹ To remedy these

²⁸ *Id.*, pg. 12.

²⁹ S&L Report SL-014000, pg. 2.

³⁰ Stamper Report, pg. 12.

³¹ *Id.*, pg. 13.

alleged deficiencies, Ms. Stamper prepared alternate control technology cost estimates using EPA’s IPM cost modules.³²

As described in more detail below, Ms. Stamper’s assertion that control technology costs prepared by S&L were developed using an “all in” methodology rather than the methodology described in the *Control Cost Manual* is not accurate. Furthermore, the IPM cost modules on which Ms. Stamper relied to generate alternate control technology costs do not provide unit-specific costs, were not prepared in accordance with the BART Guidelines nor the methodology described in the *Control Cost Manual*, and should not be used as the basis for a unit-specific BART determination.

1.0 BART Guidelines – Cost Estimating Requirements

The BART Guidelines describe, among other things, how agencies should estimate costs and evaluate the cost-effectiveness of available retrofit technologies.³³ Section IV.D.4.a of the BART Guidelines describes the following steps when developing a BART control technology cost estimate:

1. Identify the emissions units being controlled;
2. Identify design parameters for the emissions controls; and
3. Develop cost estimates based on those design parameters.

To maintain and improve consistency in the development of case-by-case BART cost estimates, the BART Guidelines suggest that “cost estimates should be based on [EPA’s] *Control Cost Manual*, where possible,” and that facilities should include documentation for any additional information used in the cost calculations.³⁴

Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

The *Control Cost Manual* describes a cost-estimating methodology that can be used by persons having knowledge of the source being controlled to produce study-level cost estimates.³⁵ Although the manual does not include specific chapters for any of the SO₂ technologies included in ADEQ's BART evaluation, it does describe a methodology that can be used to develop study-level costs.³⁶

The cost estimating procedures described in the *Control Cost Manual* consist of the following five steps:

- 1) obtaining the control system design parameters and regulatory options for a given facility;
- 2) roughing out the control system design;
- 3) sizing the control system components;
- 4) estimating the cost of these individual components; and
- 5) estimating the costs (capital and annual) of the entire system.³⁷

The *Control Cost Manual* describes the equipment and other direct costs that are included in an estimate of the Total Capital Investment (TCI) required to install a given control technology; including all costs required to purchase equipment needed for the control system (purchased equipment costs); the costs of labor and materials for installing that equipment (direct installation costs); costs for site preparation and buildings, and certain indirect installation costs (e.g., engineering costs, construction and field expenses, contractor fees, contingencies, etc.).³⁸

³⁵ *Control Cost Manual*, Section 1, Chapter 2, pg. 2-3.

³⁶ The *Control Cost Manual* does not include chapters specifically for DSI or Dry FGD controls. In fact, the manual specifically states that for certain control systems, including FGD units, it deviates from its standard approach of providing study level costs and, instead, provides a description of the factors that influence total capital cost for the analyst to consider. The *Control Cost Manual* takes this approach because "the control in question is either so large or so site-specific in design that suppliers design, fabricate, and construct each control according to the specific needs of the facility." See, *Control Cost Manual*, Section 1, Chapter 2, pg. 2-27.

³⁷ *Control Cost Manual*, Section 1, Chapter 2, pg. 2-23.

³⁸ See, *Control Cost Manual*, Section 1, Chapter 2, pg. 2-5 for a more detailed description of the costs to be included in a cost estimate developed following the *Control Cost Manual* methodology.

3.0 S&L's August 2017 Control System Cost Estimating Approach

As described in the August 2017 control technology cost basis reports, S&L prepared cost estimates for the White Bluff SO₂ control systems using an approach consistent with the BART Guidelines and *Control Cost Manual*. To develop the cost estimates, S&L:

- Established control system design parameters based on White Bluff specific data;
- Developed a conceptual design and general arrangement drawing of the major components;
- Sized the major components;
- Identified the balance-of-plant (BOP) work that would be needed to integrate the system into the existing units (e.g., civil engineering, mechanical components, demolition and relocation of existing systems, electrical system upgrades, and instrumentation and controls);
- Determined labor costs to install the equipment;
- Calculated indirect construction costs based on industry recognized factors; and
- Calculated annual operating and maintenance costs based on unit-specific design parameters.

Major equipment costs for the SO₂ control systems were based on available costs from similar previous projects, scaled for the White Bluff units, or budgetary proposals from equipment manufacturers.³⁹ Major components of the control systems (e.g., absorber vessels, particulate matter control, reactant storage and distribution, byproduct handling, etc.) were sized based on White Bluff-specific design parameters, including heat input to the boilers, fuel characteristics, flue gas flow rates and temperatures, and baseline SO₂ emission rates. Material quantities for related construction activities needed for control system installation (e.g., steel, concrete, ductwork, piping, cable, etc.) were developed by the various engineering disciplines based on the conceptual design and general arrangement drawings.

BOP costs for equipment tie-ins, ductwork, foundations, structural steel, piping, pumps, conduit, and other similar materials were estimated based on the general arrangement drawings and preliminary

³⁹ See, e.g., S&L's Report SL-012831 pg. 11, FuelTech Report dated October 17, 2016, and S&L's Report SL-014001, pg. 3.

engineering calculations. For example, S&L's structural engineers reviewed the conceptual design of the control system to calculate the quantity of structural steel and ductwork required, and provide an estimate of the number and types of foundations required to support the structure. Material quantity estimates were developed by each engineering discipline based on the conceptual design, actual quantities from similar projects, and engineering judgment. Major equipment costs and material quantities were provided to S&L's cost estimating group to develop the overall cost estimate.

A detailed description of the approach and assumptions used to develop the August 2017 cost estimates is included in each cost basis document. Design parameters, assumptions regarding the conceptual design, and cost factors used to calculate project indirect costs are all clearly described in the reports. The approach used by S&L to develop the August 2017 cost estimates is the industry standard and is used regularly by S&L and other engineering firms to prepare study level cost estimates, and is entirely consistent with the 5-step approach described in the *Control Cost Manual*.

4.0 Conservation Organization's Cost Estimating Approach

Ms. Stamper used EPA's IPM cost algorithms, with adjustments, to calculate alternative capital costs and annual control system costs for each SO₂ control technology.⁴⁰ Ms. Stamper used the revised total annual cost estimates (annualized capital recovery costs plus annual fixed and variable O&M costs) to prepare a revised cost-effectiveness analysis and demonstrate that add-on SO₂ pollution controls are cost effective even with a shortened remaining useful life of White Bluff Units 1 & 2.⁴¹ In her evaluation, Ms. Stamper asserts that the IPM cost modules "are sufficiently grounded in real costs for SO₂ pollution control retrofits for EGUs, while still being tailored to the specifics of each EGU that would effect SO₂ removal."⁴² However, as described in more detail below, costs generated using the IPM modules do not meet the requirements of the BART Guidelines or the *Control Cost Manual*, do

⁴⁰ Stamper Report, pg. 19.

⁴¹ *Id.*

⁴² *Id.*, pg. 22.

not provide unit-specific costs, and should not be used to evaluate the cost-effectiveness of BART control technologies when more appropriate site-specific information is available.

4.1 Purpose and Limitations of the IPM Model Cost Estimating Algorithms

The IPM model is described by EPA as a multi-regional, dynamic, deterministic linear programming model used by EPA's Clean Air Markets Division (CAMD) to analyze system-wide impacts of air emissions policies on the U.S. electric power sector in the 48 contiguous states and the District of Columbia. The purpose of the model is to provide forecasts of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand within specified environmental, transmission, dispatch, and reliability constraints.⁴³

The IPM cost modules were developed to support CAMD's work on the development of regulatory programs. The intended purpose of the IPM cost algorithms is to provide generic costs for various air pollution control technologies that EPA can apply to a system-wide analysis of the electric power generating industry. Cost algorithms in the IPM model were developed by S&L based on a statistical evaluation of cost data available from various industry publications, and provide order-of-magnitude retrofit costs that can be used to compare compliance alternatives.⁴⁴ By necessity, the IPM cost algorithms are designed to require minimal information that is available from publicly available sources. Inputs to the IPM DSI and dry FGD cost algorithms are limited to gross unit size (MW), fuel type, unit heat input or heat rate, and an SO₂ removal efficiency. Given the limited number of unit-specific inputs needed to generate IPM costs, the algorithms do not take into consideration site-specific costs or constructability issues and limitations, and are not intended to estimate costs for a specific unit.

⁴³ See <https://www.epa.gov/airmarkets/clean-air-markets-power-sector-modeling>, "General Purpose of EPA Power Sector Modeling".

⁴⁴ See, e.g., IPM Model—Updates to Cost and Performance for APC Technologies, Wet FGD Cost Development Methodology, Final March 2013. Prepared by Sargent & Lundy, Project 12847-002, pg. 1.

Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

Relying on the IPM cost algorithms to determine project-specific costs is inconsistent with the methodology described in the *Control Cost Manual* for at least four reasons.

- First, the IPM cost algorithms do not account for unit-specific design/operating parameters that can affect control system design and costs.
- Second, the IPM cost algorithms do not take into consideration site-specific constraints and constructability issues that can significantly affect control system design and costs.
- Third, the IPM cost algorithms do not account for site-specific limits and conditions that could affect BOP costs that a facility would incur to install the control system.
- Fourth, the IPM cost algorithms do not account for support facilities and equipment upgrades that a facility would need to install to successfully operate the control system.

4.2 *Site-Specific Constraints and Constructability Issues Affecting FGD Retrofit Costs*

The BART Guidelines state that the cost analysis should “take into account any site-specific design or other conditions...that affect the cost of a particular BART technology option.”⁴⁵ The IPM cost algorithms are not set up to identify and account for site-specific conditions that may affect control system design and costs. Examples of site-specific issues that would affect the cost of a retrofit SO₂ control system include, but are not necessarily limited to:

- Demolition and relocation of existing buildings, foundations, equipment, cables, pumps, piping, and underground utilities needed to install the SO₂ control system;
- Modifications/upgrades that may be required to the facility's material receiving, preparation, and transport systems;
- Modifications/upgrades that may be required to the unit's existing particulate removal systems;
- Modifications that may be required to the unit's existing ash handling systems;
- Impact to the existing draft system and potential need for reinforcement of existing equipment and ductwork;
- Impacts to and potential expansion of existing solid waste management and disposal facilities;
- Modifications/upgrades to the unit's existing auxiliary power system; and
- Modifications to other systems at the facility needed to successfully operate the control system.

The impact of these site constraints on the cost of a retrofit SO₂ control system must be determined during preliminary engineering and development of a conceptual level control system design, as described in the *Control Cost Manual*. By relying on the IPM cost algorithms, Ms. Stamper's cost estimates represent generic order-of-magnitude costs that do not take into consideration any site-specific constraints or limitations that could significantly affect control system costs.

⁴⁵ BART Guidelines, Section IV.D.4.a.

4.3 Cost Estimates Adjustments and Excluded Costs

Ms. Stamper used the IPM cost modules, with adjustments, to generate both capital and annual O&M costs for each SO₂ control option. Adjustments to the IPM-generated costs included removing Owner’s Costs and AFUDC, based on her assertion that these costs were not consistent with the overnight costing methodology of EPA’s *Control Cost Manual*).⁴⁶ Ms. Stamper also escalated (or de-escalated) the IPM-generated costs from 2012 (the year the cost algorithms were published) to 2016. Each adjustment is discussed below.

4.3.1 Allowance for Funds Used During Construction

Ms. Stamper excluded AFUDC from the IPM-generated capital costs, asserting that AFUDC (Allowance for Funds During Construction, or the interest paid on funds used during the construction project) are not allowed under the *Control Cost Manual*’s overnight costing methodology.⁴⁷ However, we see nothing in the *Control Cost Manual* that suggests capital costs calculated using the methodology described in the manual represent overnight costs. In fact, the definition of total capital investment (TCI) in the manual appears to include all costs required to purchase and install the equipment.⁴⁸

⁴⁶ Stamper Report, pg. 22.

⁴⁷ *Id.*, pg. 40.

⁴⁸ Section 2.3 of the *Control Cost Manual* (Section 1, Chapter 2) describes the cost categories used in the manual. Cost categories defined in Section 2.3 include total capital investment (TCI). TCI is defined in the manual to “include all costs required to purchase equipment needed for the control systems (purchased equipment costs), the costs of labor and materials for installing that equipment (direct installation costs), costs for site preparation and buildings, and certain other costs (indirect installation costs). TCI also includes costs for land, working capital, and off-site facilities.” Direct installation costs include costs for foundations and supports, erecting and handling the equipment, electrical work, piping, insulation, and painting. Indirect installation costs include costs such as engineering costs; construction and field expenses (i.e., costs for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system running and to verify that it meets performance guarantees); and contingencies.

The cost estimating methodology in the *Control Cost Manual* is more accurately described as a constant dollar approach. Control system costs, including capital costs, annual maintenance costs, and annual operating costs, are annualized (in constant dollars) over the life of the system. The manual recommends translating the costs in each future year to year zero using an equivalent uniform annual cash flow method and real interest rate (excluding inflation).⁴⁹

AFUDC accounts for the time value of money associated with the distribution of construction cash flows over the construction period, which for a DFGD project could be spread over a construction period of approximately 36 months. AFUDC can be calculated as a capital cost and annualized over the life of the project using the equivalent uniform annual cash flow method. AFUDC can represent a significant cost on large construction projects with long project durations, and excluding AFUDC will skew the results of a cost-effectiveness evaluation towards high capital, long-duration projects. Nevertheless, Entergy provided cost estimates that did not include AFUDC in its August 2017 Revised BART Analysis, and ADEQ relied on these costs estimates to determine BART for White Bluff Units 1 & 2.⁵⁰

4.3.2 Owners Costs

Ms. Stamper also excluded "Owner's Costs" from the IPM cost estimates, arguing that the costs were not allowed under the *Control Cost Manual* methodology.⁵¹ Indirect installation costs are defined in the *Control Cost Manual* to include "costs such as engineering costs; construction and field expenses (i.e., costs for construction supervisory personnel, office personnel, rental of temporary offices, etc.); contractor fees (for construction and engineering firms involved in the project); start-up and performance test costs (to get the control system

⁴⁹ *Control Cost Manual*, pg. 2-18.

State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

running and to verify that it meets performance guarantees); and contingencies.”⁵² The definition of indirect costs in the manual is expansive and does not preclude owner’s costs, as that term was used in S&L’s 2017 cost estimates.

As described in S&L’s 2017 Cost Reports, owner’s costs include the project-related costs that would be incurred to purchase, engineer, manage, administer, and implement the construction project.⁵³ These necessary costs include expenses such as internal labor and management costs, travel expenses, legal services, and builders risk insurance. Owner’s costs clearly fall within the *Control Cost Manual*’s definition of indirect costs. Owner’s costs are also included in specific air pollution control examples in the *Control Cost Manual*, generally under the line item “Engineering & Home Office” and are calculated as a percentage of the total direct capital costs.⁵⁴ Nevertheless, Entergy provided cost estimates that did not include owner’s costs in its August 2017 BART analysis, and ADEQ relied on these costs estimates to determine BART for White Bluff Units 1 & 2.⁵⁵

4.3.3 Using the Chemical Engineering Plant Cost Index (CEPCI) to Escalation Total Annual Costs from 2012 to 2016

Ms. Stamper adjusted the IPM-generated costs for each control technology by escalating the total annual cost (i.e., annualized capital plus annual O&M costs) from 2012 to 2016 using the Chemical Engineering Plant Cost Index (“CEPCI Index”).⁵⁶ This approach is incorrect because the CEPCI index should not be used to escalate (or de-escalate) annual O&M costs.

⁵² *Id.*

⁵³ See, e.g., S&L’s Report SL-012831, pg. 19.

⁵⁴ See, e.g., *Control Cost Manual*, Section 4.2, Chapter 2 (Selective Catalytic Reduction), pg. 2-44.

⁵⁵ Entergy’s August 18, 2017 Revised BART Analysis.

⁵⁶ Stamper Report, pg. 5.

Sargent & Lundy L.L.C.
Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

The CEPCI Index consists of a composite index and several sub-indexes. Plant cost indexes that make up the composite index include Equipment, Construction Labor, Buildings, and Engineering and Supervision. Indexes are compiled and, with weighting and normalizing factors, are summed to make the composite CEPCI Index.

The CEPCI Index was developed to provide a simplified method of escalating construction costs associated with chemical process equipment and chemical process plants. While some of these types of process equipment are used in air pollution control systems, most are not. Thus, weighting factors based on the chemical processing industry to develop the composite CEPCI Index would not be representative of air pollution control systems.⁵⁷ Furthermore, the CEPCI Index does not take into consideration other market forces and site-constructability issues that will affect the cost of retrofit air pollution control systems.

More importantly, Ms. Stamper used the CEPCI index to adjust both capital costs (annualized) and annual O&M costs. The CEPCI index should not be used to adjust annual O&M costs, especially commodity costs. Commodity costs should be based on recent pricing from vendors or publically available commodity price indexes. Applying the CEPCI index to escalate costs is especially inaccurate for the DSI control options. For example, O&M costs account for approximately 40% of the total annual costs for the 50% DSI option (i.e., \$23.76MM/yr. capital recovery and \$14.91MM annual O&M), and reagent costs (Trona) account for approximately 70% of the total annual O&M costs (i.e., \$10.55MM of the \$14.91MM annual cost).

By applying the CEPCI construction cost index to both annualized capital costs and annual O&M costs (including reagent costs) Ms. Stamper incorrectly adjusted total annual costs of

⁵⁷ See, Vatavuk, *Air Pollution Control Escalate Equipment Costs*, Chemical Engineering, December 1995, pg. 89, available at <http://infohouse.p2ric.org/ref/27/26839.pdf>.

Sargent & Lundy L.L.C.
Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

the SO₂ control systems downward by more than 7% (based on a 2012 index of 584.6 and 2016 index of 541.7). This approach is especially inaccurate for the DSI options given the fact that Trona costs during that time period remained constant or slightly increased.⁵⁸

⁵⁸ See, e.g., Solvay press release indicating a \$20/ton price increase for Trona in 2015.
https://www.solvay.us/en/media/press_releases/2015-09-24-Bicar-Trona-Price-Increase.html

D. Correction to S&L's DSI Cost Estimate Basis Report

On Page 9 of her report, Ms. Stamper discusses the basis of the proposed DSI emission rate, "Entergy has also proposed an SO₂ emission limit achievable with this control of only 0.35 lb/MMBtu based on a maximum 30-day average from 2014-2016 of 0.66 lb/MMBtu. It is not clear why Entergy used 2014-2016 data when its cost analysis is based on a 2009-2013 baseline."⁵⁹

S&L notes that the reference to the 2014-2016 data was an error. The 0.66 lb/MMBtu maximum 30-day average that appears in S&L's Report does reflect the maximum 30-day average from 2009-2013 and not 2014-2016 as the text states.

⁵⁹ Stamper Report, pg. 9.

E. Summary and Conclusions

Based on information provided herein, and detailed cost estimating information provided in the 2017 Cost Basis Reports, ADEQ reasonably relied on Entergy's August 18, 2017 Revised BART Analysis for White Bluff Units 1 & 2 for the following reasons:

- Control system cost estimates prepared by S&L (August 2017) and relied on by ADEQ for its revised BART determination, were:
 - Established using an appropriate baseline period;
 - Established using appropriate design and operating parameters;
 - Developed using an approach meeting the BART Guidelines and in accordance with the approach and methodology described in EPA's *Control Cost Manual*.
- S&L sized the SO₂ control system components based on a reasonable estimate of the maximum SO₂ inlet rate to the control system. Sizing the major system components based on an average SO₂ inlet rate would result in inadequately sized systems that would not ensure compliance with emissions limits.
- Annual O&M costs for the DSI options were calculated assuming either 50% or 80% SO₂ removal from an uncontrolled SO₂ rate of 0.57 lb/MMBtu, the annual average SO₂ emission rate during the baseline period.
- The approach used by S&L to calculate capital costs and O&M costs was appropriate based on sound engineering principals, and did not inflate the capital costs or operating costs of the control system.
- Based on the significant increase in particulate loading to the ESP with DSI, ESP performance modeling with and without DSI, and input from an ESP equipment vendor, it is very likely that the ESPs would have to be rebuilt as part of the DSI project to ensure that the air pollution control project would not trigger PSD permitting, and costs for the ESP rebuild should be included in the BART cost evaluation.
- By removing ESP upgrade costs, Ms. Stamper significantly underestimated the capital costs Entergy would incur to implement DSI at 50% control.

Sargent & Lundy L.L.C.
Comments on the Conservation Organization's Technical Support Document
Arkansas Department of Environmental Quality's October 2017 Proposed Revisions to the Arkansas
State Implementation Plan Regional Haze SIP for 2008-2018 Planning Period
Prepared by Victoria R. Stamper, February 1, 2018

- Ms. Stamper used EPA's IPM cost algorithms, with adjustments, to calculate alternative capital costs and annual control system costs for each SO₂ control technology.⁶⁰ However, costs generated using the IPM modules do not meet the requirements of the BART Guidelines or the *Control Cost Manual* for the following reasons:
 - The IPM cost algorithms do not account for unit-specific design/operating parameters that can affect control system design and costs;
 - the IPM cost algorithms do not take into consideration site-specific constraints and constructability issues that can significantly affect control system design and costs;
 - the IPM cost algorithms do not account for site-specific limits and conditions that could affect BOP costs that a facility would incur to install the control system; and
 - the IPM cost algorithms do not account for support facilities and equipment upgrades that a facility would need to install to successfully operate the control system.
- Ms. Stamper incorrectly removed AFUDC and Owner's Costs from her capital cost estimates.
- Ms. Stamper incorrectly escalated (de-escalated) total annual costs generated using the IPM cost modules (i.e., annual capital plus annual O&M) using the CEPCI Index. The CEPCI index should not be used to escalate O&M costs or commodity costs.
- Costs generated by the IPM cost modules represent order-of-magnitude costs that do not take into consideration site-specific operating parameters, site constraints, and balance-of-plant costs that could have a significant impact on control system costs, and, as a result, should not be used as the basis for a site-specific BART determination.

Re: Supplement to Comments Submitted by Entergy Arkansas, Inc. on ADEQ's Draft Phase II Regional Haze SIP: SO₂ Compliance Deadline for White Bluff Electric Generating Station

Dear Ms. Treece:

On February 2, 2018, Entergy Arkansas, Inc. ("EAI") submitted comments on the draft Phase II state implementation plan ("SIP") to address certain regional haze requirements, which ADEQ released for comment on October 31, 2017 ("Draft SIP"). The Draft SIP proposed rolling 30-boiler operating day sulfur dioxide ("SO₂") limits of 0.6 lb/mmBTU for each of the two coal-fired electric generating units at White Bluff. The SO₂ limits are based on ADEQ's determination that a switch to low sulfur coal constitutes best available retrofit technology ("BART") for the White Bluff units. ADEQ proposed a compliance deadline of three years from the date of the U.S. EPA's final approval of the SIP to allow EAI sufficient time to make the switch to low sulfur coal at White Bluff.

As a follow up to public comments on the Draft SIP, ADEQ has requested additional support for EAI's need for three years to meet the SO₂ BART limits. As EAI explained in its comments on the Draft SIP, the company's practice is to contract for a portion of its coal supply for up to three years in advance and the company also is required to keep a reserve supply of coal on site to ensure that the White Bluff units can continue to operate in the event of a fuel supply disruption. EAI Comments on the Draft SIP at 7-8 (Feb. 2, 2018).

The current coal contracts limit the sulfur content of delivered coal to 1.2 lb/mmBTU or less. Although the coal delivered to White Bluff has lately been of lower sulfur content, our experience is that the sulfur content can vary widely, which means that White Bluff cannot ensure that it will receive coal with a low enough sulfur content to ensure compliance with the BART SO₂ limits until the company has had sufficient time to negotiate new contracts and the existing coal pile has been depleted and replaced with lower sulfur content coal. This is because, even if EAI were to purchase lower sulfur coal for the uncontracted portion of its projected coal supply needs over the next few years, White Bluff does not have fuel blending capability on site sufficient to ensure compliance with the SO₂ BART limits. Although the plant can achieve crude fuel “blending” by simultaneously feeding coal from the stockpile and directly from a train, the plant does not track the sulfur content of coal fed onto the stockpile and thus cannot accurately calculate the expected SO₂ emissions where a portion of the total coal feed is from the stockpile and a portion is fed directly from a train. In addition, due to minimum belt speeds, this crude blending ability is limited at low-load and/or single-unit operating scenarios.

For the next three years, EAI forecasts its coal consumption to be between 11.5 and 12.4 million tons per year, approximately half of which can be attributed to White Bluff. EAI currently has contracted for 9.9 million tons of coal for 2018 under the sulfur specification of <.9 lbs/mmBtu. For 2019, the forecast is for 11.5 million tons of coal, approximately 6 million tons of which already has been contracted with a sulfur specification of <.7 lbs/mmBtu. For 2020, EAI forecasts needing 12.4 million tons, and has contacted for 3 million tons to date, also with a sulfur specification of <.7 lbs/mmBtu. If EAI were to cancel its current contracts, the company would face significant financial penalties. The contractual provisions relating to penalties for cancellation are confidential and could be subject to litigation, so EAI is unable to divulge this information to ADEQ. Before making any purchasing decisions on lower sulfur coal that has not previously been used at White Bluff, EAI will need to allow time to conduct test burns.

Given the current coal contracts and the fuel blending limitations, it would be difficult for the White Bluff units to assure compliance in less than three years with the rolling 30-boiler operating day SO₂ emission limits of 0.6 lb/mmBTU and the plant would risk exceeding the limits. Accordingly, EAI requests that ADEQ finalize a three-year compliance deadline for the White Bluff units to meet the SO₂ BART limits.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Keaton Smith

Subject: Please stop Entergy plants from polluting Arkansas and Missouri!
Date: Wednesday, January 17, 2018 6:09:28 PM

Dear Arkansas Department of Environmental Quality,

New data show that the Clean Air Act has saved 80,000 more lives than initially estimated. As a biomedical scientist, and someone whose never-smoking family has severe asthma due to air pollution, I implore you MAKE OUR AIR CLEANER!!!

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Janine Perlman

Subject: Stop polluting Arkansas and Missouri
Date: Wednesday, January 17, 2018 7:34:59 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

Even Exxon, China, India and are divesting from coal to safe renewables. We all know coal is dead. We need to retrain the coal workers to make solar panels and wind turbines. Do the right thing.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Yvonne Segal

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

Dear Arkansas Department of Environmental Quality,

So the "Natural State" is working towards a new motto - the "Toxic State". That should really encourage businesses to invest in doing business in Arkansas. I'm sure it'll be quite the enticement for corporations and employees alike.

And I'm sure our healthcare system in America will take care of these issues without any problems.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Andy Winger

Dear Arkansas Department of Environmental Quality,

Missouri does not need pollution from other states. Hard enough to have Missouri's government put restraints on its polluters.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 5:21:20 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Barbara Bagby

Dear Arkansas Department of Environmental Quality,

Please stand strong for clean air for your customers. As a major corporation, please respect the planet and its resources. In addition, please move forward with renewable energy in your strategic planning for your corporation. We, as a progressive nation along with all major world leaders, are concerned about climate change and the need to become diverse in our energy resources.

Dear Arkansas Department of Environmental Quality,

As an Arkansan with family in St. Louis, I am disgusted by Entergy's management of these coal plants and their effect on the air. There is no good reason for Arkansan energy sources to be considered the dirtiest.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Bill Page

Date: Monday, December 18, 2017 11:54:10 AM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Carmine Coscia

Dear Arkansas Department of Environmental Quality,

We need to make coal clean, or, it will need to go! Consumers would pay a few more cents to breath fresh air. But the technology needs to be used.

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Monday, December 18, 2017 5:32:12 PM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Cecelia Thompson

Dear Arkansas Department of Environmental Quality,

Entergy is also much more expensive than our rural coops. They are pocketing a huge amount of profit. This profiteering on the backs of their customers and their neighbors is unacceptable. Clean it up NOW. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

Dear Arkansas Department of Environmental Quality,

As someone with family members in both AR and MO, this is extremely upsetting. If you're going to continue to burn dirty coal rather than converting to cleaner technologies, at least add catalytic reduction to your power plants!

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Christopher Pinne, SJ

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Danny Jenkins

Subject: Stop Entergy plants from polluting skies over Arkansas and Missouri
Date: Thursday, January 18, 2018 1:26:42 AM

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Dian Copeland

This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Edward Hejtmanek

Dear Arkansas Department of Environmental Quality,

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppb, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Dear Arkansas Department of Environmental Quality,

Why? Why do we need to pollute? Why? How can you sleep at night? Don't answer to me, tell your grandchildren how we are so lazy that we don't mind ruining everything we touch. Good luck to the next generation because we don't care what we leave you!

Dear Arkansas Department of Environmental Quality,

Why should my grandchild's very breath subsidize a coal plant's bottom line? Her asthma is not her fault---it's yours, Entergy. Shame on your criminality! Try finding some morals and ethics in your company.

In reference to: "Revisions to the Arkansas State Implementation Plan Regional Haze SIP Revision for 2008-2018 Planning Period, October 2017"

I am very concerned about the impact of Entergy's White Bluff and Independence coal plants on the air quality of Arkansas and Missouri. There is a plan already in place from 2016 that would require both plants to clean up emissions. Unfortunately, your agency appears willing to remove those requirements and replace them with a weak new plan that will allow those plants to continue operating with high emissions.

There is a troubling new report about the impacts of the emissions from the Entergy's plants on the people of St. Louis. The report, by scientists at Sonoma Technology Inc., demonstrates that those two plants are emitting enough pollution to make the unhealthy ozone smog problems worse in St. Louis. Smog-forming emissions from the Entergy White Bluff and Independence plants are elevating ozone levels by more than 3.6 ppm, many times the level of significance. This report further demonstrates that the Entergy plants are elevating levels of ozone in the St. Louis area 22 days per summer. The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Fran Alexander

Dear Arkansas Department of Environmental Quality,

Not only are these plants environmentally unsound, they are an embarrassment to our state!!

The technology that could reduce smog and haze forming emissions from these coal plants - so-called "selective catalytic reduction" - has been available for more than 20 years, but these plants are not using it.

I strongly support the existing 2016 clean air plan that would require the two plants to greatly reduce their emissions, and I strongly oppose the weak plan that ADEQ is currently considering. Whether its for the sake of clearing the skies on federal lands like the Upper Buffalo Wilderness Area in Arkansas or in the Mark Twain National Forest in Missouri, or especially for the sake of protecting human health from higher levels of smog in cities like St. Louis, please clean up emissions from the Entergy coal plants as soon as possible.

Sincerely,

Ginny Masullo
